When melting, the precipitates are charged semi-dry without acid treatment and with crucible and furnace cold. A crucible cover having a special condenser attached is used, and as the temperature rises the zinc is distilled early in the melting process.

Power for all purposes except precipitation is furnished by a 30-hp. three-phase 30-cycle G. E. induction motor of the old and heavy type. It will carry a 50% overload for indefinite periods. It drives the lineshaft with a short belt using—on the slack side of the belt—a swinging idler pulley, an arrangement which gives a large arc of belt contact with both pulleys without any unnecessary belt tension and requiring but little room and a short belt. The small amount of power required by the zinc-dust apparatus is supplied by the flow of solution.

Mineral Output of Sweden

The official report of Swedish mineral production shows the following: Iron ore, 6,586,630 metric tons; bituminous coal, 366,639; gold ore, 639; silver-lead ore, 3,100; molybdenite, 7; copper ore, 8,839; manganese ore, 3,643; zinc ore, 42,279; nickel ore, 156; pyrite, 33,313; feldspar, 20,818; quartz, 36,128; copper sulphate, 158; iron sulphate, 651; graphite, 56; powdered pyrolusite, 81 metric tons.

Owing to the war, the production of iron ore decreased about 11.9% from the figure of last year (7,475,571). Of the iron ore produced, 3,966,863 tons carried 60 to 70% Fe. There were 8,732 metric tons of ferro-silicon produced, 1,304 of ferromanganese-silicon, 1,300 of ferrochrome and 865 of all other ferro alloys. At Höganäs there were 6,394 metric tons of sponge-iron produced. Slig production was 620,591 metric tons.

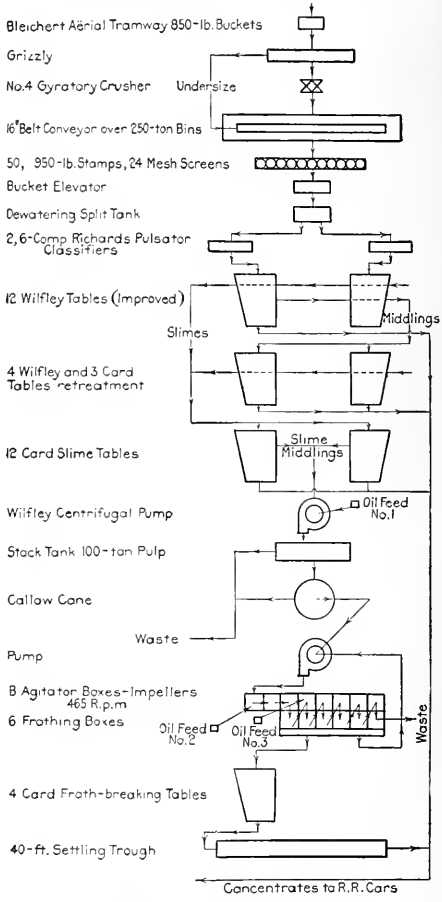
The metal production, excluding iron, was: Gold, 84 kg.; silver, 1,074; lead, 1,395,566; copper, 4,692,244, and zinc, 2,299,761 kg.

Concentrating Gold King Ores

By Warren C. Prosser*

The Gold King mine at Gladstone, San Juan County, Colo., has made a good production record, the total value of which is estimated to be in excess of $12,000,000. The property has suffered from continued heavy mill losses and high-grading.

The development early disclosed the valuable Gold King and Davis veins and has since opened many other profitable veins and stringers, together with irregular occurrences of free gold ore worth up to $15 per lb. These have proven a big factor in inducing sublessees to under-



FLOW SHEET, GOLD KING MILL

take the exploitation of various blocks of ground. A fault, which passes through the mine in a northerly direction, was explored several years ago, and the vein—containing some ore—opened beyond was called the Becker vein.

An irregular system of variable quartz stringers, separated by altered and decomposed horses of andesite, forms the orebody. It contains much iron pyrite, the greasiness

*Mining engineer, Silverton, Colo.

occupied. It requires little power, and repairs are quickly and easily made. The use of the 100-ton sand-storage bin, placed high enough to enable filling the leaching tanks through launders, not only gives storage, avoiding stoppage of the leaching plant in case of delay at mine or crushing plant, but also makes it possible to charge a 75-ton leaching tank—using the rotating distributor—and level the charge with the excavator in less than 30 min. A sliding gate combined with deflectors at the outlet of the sand bin controls and directs the flow of the sand to the distributors. It is operated by a lever having ropes reached conveniently from the ground floor.

Sand Distributor and Excavator

The excavator consists essentially of a four-arm plow, made of 2-in. pipe and equipped with sheet-steel blades, or rabbles, which resemble those used with circular mechanical roasting furnaces. This plow is rotated around the central 5-in. pipe column by a wheel 2 ft. less in diameter than the leaching tank. This wheel has arms and rim of 2-in. pipe, with small rods extending from the upper hub to the rim. Wooden blocks clamped on the rim in pairs about 12 in. apart constitute an interrupted groove for the driving rope.

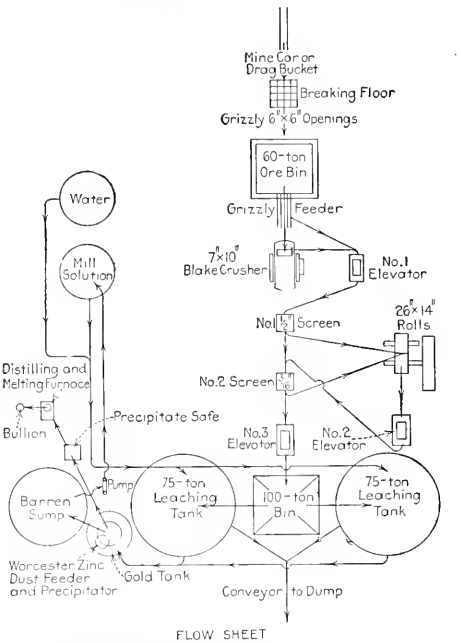
The rope is guided from the jackshaft which drives it to the plow wheel by one stationary sheave and one horizontally movable sheave, which is used as a tightener. When the tightener is relaxed and the plow stopped, the same movement throws a curved lifter between the sheave and the rope, taking the rope clear of the sheave and preventing rubbing. When charging a leaching tank the operator first puts the rope drive in action, using the tightener. He then opens the deflector gate, allowing 3 to 5 tons of sand per minute to flow from the sand bin to the distributing spout, which is mounted on the rotating plow wheel. The hinged end of the spout is then moved, a little at a time, toward the center of the tank as fast as it fills. The plow, hung up close to the wheel, smooths out the ridges and the charge is leveled as the tank is filled. The hinged spout is retained at any desired angle by a telescoping rod with a screw clamp. When excavating and discharging tailings the plow is lowered so as to rest its weight on the charge. A gate beneath the center column is opened and an opening punched through the sand. The plow and conveyors are put in motion, and the plow blades move the tailings to the center, where they drop through the gate to the short conveyor below.

Tailings Stack Formed by Conveyors

The short conveyors deliver to a long bridge conveyor which is pivoted and radially movable. This conveyor has radial movement both vertically and horizontally and covers a large dumping space before extension is necessary. Its outer end is supported by a ratchet jack of 5-ft. lift. When the tailings pile has grown so that the conveyor has been raised to the extreme angle at which sands will carry without running backward, the horizontal radial movement will begin, the jack being pinched along or around the arc on planks laid on flats dug in the tailings pile. An A-shaped tripper is made so that it can be clamped to the bridge at any point in its length. It scrapes the sands off equally on both sides of the belt. The sands are dry enough to pile with slopes of 38° from the horizontal. By occasionally moving the tripper and by radial movement of the conveyor both vertically and horizontally, any one of these operations requiring but a few minutes' time, the available dumping ground is fully utilized. The bridge conveyor is driven from the same jackshaft that drives the two short conveyors and the excavators. The belt tension and direction are easily and quickly adjusted by two movable idler pulleys which are set to suit any change of position of the bridge. The time required to discharge a 75-ton tank is about 2½ hr., so that but little time is lost in charging and discharging and the plant is kept up to capacity.

Usual Methods of Tailings Disposal

The almost invariable method of using tailings conveyors in this district has been to start with a stationary conveyor 25 to 40 ft. long on one or more high trestles and then patch on additional conveyor 10 or 20 ft. at a time,



FLOW SHEET

TREATMENT SCHEME FOR CYANIDE PLANT

building new trestles for each extension. The high trestles are expensive when built on solid ground, and when the usual short trestles are built on tailings heaps they settle irregularly and the conveyors run miserably. When one pile has reached the property line a new string of trestles and extensions is begun in another direction. Trippers are not used, and the one point of delivery is at the end of the conveyor. Patching an extension on the end of one of these conveyors on the top of a tailings heap in stormy, zero weather is a very undesirable job, and the contrivance is always getting out of order. The main drive has to be remodeled every time the direction of the conveyor is changed, and the conveyor is usually the worst nuisance around the plant.

On the other hand, the bridge conveyor here shown costs no more than a trestle conveyor of equal length, and it will pile to the limit all of the ground within its radial reach without any new construction or alter-

Simple Cyanide-Plant Design

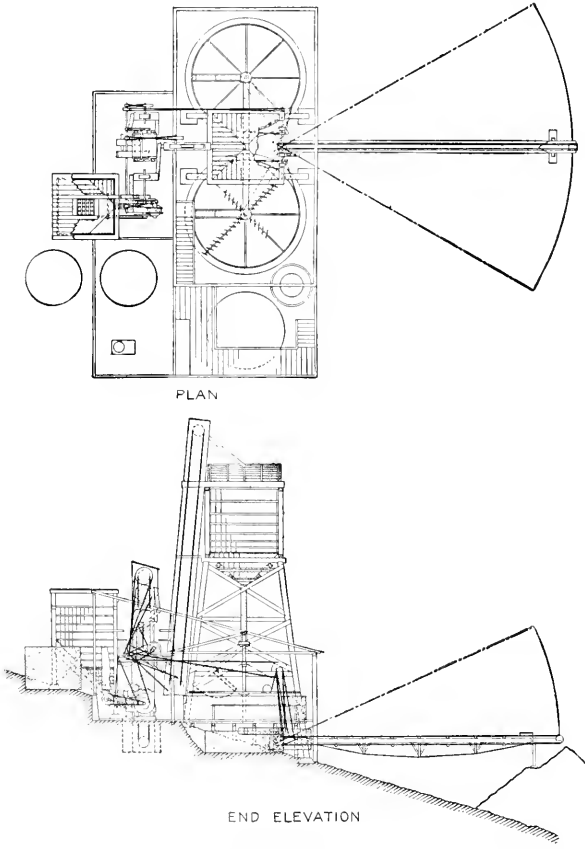
By S. A. Worcester*

SYNOPSIS—A highly oxidized ore, free from cyanicides, is treated by moderately coarse crushing and simple leaching. Automatic appliances and conveniences minimize labor and give maximum capacity. Limited space available for tailings is fully utilized. A new zinc-dust feeder and precipitator is used. Acid treatment of precipitates is eliminated.

This plant, which I recently designed for a local mine in which I am interested, has a capacity of 30 tons daily, treating a friable, thoroughly oxidized ore well-adapted to simple cyanidation. The mill, although small, is highly automatic and includes a number of simple and inexpensive devices which save labor and attendance and insure satisfactory and continuous operation. After passing the coarse grizzly above the 60-ton coarse-ore bin, the material is handled entirely by elevators, launders, excavators and conveyors, and all manual labor is avoided.

The ore, carrying about $4 per ton in gold, is dumped on the coarse grizzly either by the car from the mine or by the drag-bucket of the dump excavator. The attendant who delivers the ore breaks any oversize, and as about 99% of the ore will pass the grizzly without breaking, very little hammer work is necessary. Any coarse waste carrying less than $1 per ton is rejected at this point and sent to the waste dump.

Failure to eliminate coarse and entirely unprofitable waste from the material treated has been the cause of immense losses at several of the mills of this district. A large tonnage of rock averaging less than 50c. per ton in gold is being regularly treated along with the better rock, at a cost exceeding $1 per ton. This low-grade waste is nearly all in large pieces and could easily be sorted out and rejected at a cost not exceeding 15c. per ton. The feed to the crushing plant is regulated partly by adjusting the gate at the mouth of the storage bin and partly by varying the stroke of the oscillating fingers which serve the double purpose of keeping the stationary grizzly clean and feeding the oversize to the crusher. Fully 30% of this ore will pass the 1-in. grizzly spaces and is elevated to the screens, thus increasing the effective work of the crusher by eliminating the undersize and also reducing the production of fines, which have a detrimental effect on percolation. The screens following the crusher also eliminate undersize, sending it direct by elevator to the sand storage, this procedure having a beneficial effect on the work of the rolls, giving a more uniformly granular product and economizing power. The impact screen was chosen as the result of experience. It has great efficiency per foot of screen surface and space



DESIGN FOR A COMPACT CYANIDE PLANT USING BELT-CONVEYOR TAILINGS DISTRIBUTORS

*Mechanical engineer, Victor, Colo.

The lead present in the gray slag is approximately combined as follows:

	%
$PbSO_4$	10 0
PbS	6 0
PbO	25 0
Metallic lead	8 5

From the standpoint of roasting, the elimination of sulphur on the hearth is high in comparison with the other methods now in vogue.

Of the material drawn into the flues and bag chambers the proportion by weight is one of dust to two of burnt fume. From the analyses given below it will be seen that a considerable portion of the lead is present as sulphate, and on retreatment the sulphate, reacting on the sulphide, greatly assists the desulphurizing process.

	Pb, %	S, %
Dust	62 0	11 1
Burnt fume	76 0	5 9

The lead present is combined approximately as follows:

	Dust, %	Burnt Fume, %
$PbSO_4$	18 9	53 6
PbS	55 4	1 2
PbO	2 0	41 5

Taking the foregoing average runs as a basis, the sulphur elimination is calculated as follows:

NEWNAM HEARTH

	Lb.	Sulphur, %	Sulphur, lb.
Dry ore charged	13,179	15 1	1,990
Gray slag	3,318	1 9	63
Dust	776	11 1	86
Burnt fume	1,552	5 9	92
Pounds of sulphur eliminated			1,749
Per cent. of sulphur eliminated			87 9

HAND HEARTH

	Lb.	Sulphur, %	Sulphur, lb.
Dry ore charged	5,091	15 1	769
Gray slag	1,329	2 6	35
Dust	497	11 1	55
Burnt fume	994	5.9	59
Pounds of sulphur eliminated			629
Per cent. of sulphur eliminated			80 6

In several localities the ore hearth has been operated on high-grade galena containing about 80% lead, with an extraction of from 80 to 85% of the metal. In order to determine the adaptability of this grade of ore to the Newnam hearth a test run was made, the average results of which per 8-hr. shift are given here:

TEST ON GALENA CONCENTRATES, CONTAINING 82 0% LEAD AND 11 2% SULPHUR

	Lb.
Dry ore charged	14,436
Lead contents	11,837
Pig lead made	10,790
Gray slag made	1,075
Per cent. of coke breeze used	2 4
Per cent. of crushed limestone	2 0

Percentage of Total Lead Products

Pig lead	91 15
Gray slag	4 25
Dust and fume	4 60
	100 00

Sulphur Elimination

	Lb.	Sulphur, %	Sulphur, lb.
Dry ore charged	14,436	11 2	1,617
Gray slag	1,075	2.5	27
Dust	254	11.1	28
Burnt fume	508	5.9	30
Pounds of sulphur eliminated			1,532
Per cent. of sulphur eliminated			94.7

Beaver Consolidated Report

For the quarter ended Aug. 31, 1915, the Beaver Consolidated Mines, Cobalt, Ont., reports that 1,600 ft. of development work was performed and 1,133.5 cu.yd. removed in stoping. The main shaft is down to 1,100 ft. and will be continued until it reaches the lower contact between the diabase and Keewatin formations. Additions to the mill will increase its daily capacity to 150 tons. Owing to the low price of silver, the company now has 235,075 oz. of bullion in storage in New York. There is also 22,801 oz. due from smelters and 56,634 oz. are contained in ore bagged at the mine. The company has $116,017 in cash.

A. I. M. E. Excursion Around San Francisco Bay

EDITORIAL CORRESPONDENCE

Cottrell and baghouse methods were demonstrated to the members of the American Institute of Mining Engineers that visited Selby, Calif., on Sept. 18. The visitors, including ladies of the party, numbered 198 and were guests of D. C. Jackling aboard his yacht "Cyprus." The A. I. M. E. convention at San Francisco closed on Sept. 17, and the following day was given over to various excursions, of which the yacht cruise was one of the most interesting.

The various points of interest in San Francisco Bay were visited before and after the stop at the smeltery. Just prior to the landing of the yacht at Selby, the dampers were opened and the smoke and fumes poured out of the stack in large and dense volumes, giving a very positive demonstration of the conditions that accompanied the smelting of ore several years ago, which conditions caused a great deal of complaint by farmers, resulting in the installation of the baghouse and the Cottrell system. Within a few minutes after the smoke had been allowed to escape, and at a given signal, the dampers were changed, throwing the smoke and fumes through the Cottrell and the baghouse, demonstrating clearly and practically to the visiting engineers a successful application of these methods of eliminating fume.

The courtesy of Mr. Jackling in placing his yacht at the disposal of the members of the Institute, and of Eugene Braden, manager of the smeltery, in providing the demonstration, was highly appreciated. The excursion gave the members and their ladies a delightful cruise on San Francisco Bay and showed them in a practical way that the control of smelting fumes not only can be, but has been, accomplished.

Chronology of Mining for September, 1915

Sept. 1—Price of silver went to 46¼c., the lowest on record.

Sept. 2—Crushing started in Nevada-Douglas mill.—Entire holdings of Tin Cup Gold Dredging Co. sold by the United States Court of Bankruptcy.

Sept. 10—Final decree of the Circuit Court filed at Trenton, N. J., dismissing suit against the United States Steel Corporation.

Sept. 11—Strike of miners at Clifton and Morenci, Ariz.

Sept. 14—Investigation of alleged zinc-smelting trust in Missouri started at Joplin.

Sept. 15—Holdings of Pittsburgh & Lake Angeline Co. sold to Cleveland-Cliffs Iron Co.

Sept. 17—Teck-Hughes taken over by Buffalo Mines.

Sept. 22—National Association of Mining and Stock Brokers organized at San Francisco.

Sept. 25—Old board of directors of Northport Smelting and Refining Co. resigned and new board elected.

purpose of this paper to describe a new and more fortunate endeavor in this direction.

After a careful study of the hand-hearth operation, it was decided that three things were necessary to perfect it, namely: A cool and sanitary hood; a mechanical rabbler that would effectually replace the continuous and laborious use of the hand rabble; and a lead-well attachment that would mold clean lead direct from the hearth basin with little attention on the part of the furnacemen.

All our experiments were carried out on the ordinary 4-ft. hand hearth. The hood problem was taken up first, and soon a double hood was devised which gave the furnace room a clear and fume-free atmosphere, at the same time reducing the direct and radiated heat to the workmen by 50%. A complete cessation of sickness and an increased output were at once noted. After a few trials a simple and effective lead well and molding device was installed. A traveling rabbler was next put on the 4-ft. furnace, and after numerous changes a successful type was worked out.

Mechanical Rabbler the Chief Stunt

This rabbling machine is hung from a carriage which travels on an overhead track, and it rabbles in one direction only, for a reason given later. The machine being in such a position that the rabble arm is at the extreme end of the furnace, a releasing lever is pulled, which starts the machine, causing the rabble arm to describe a motion similar to that of the hand rabble, but more effective, since there is more power behind it. As the rabble arm is withdrawn from the fire, an eccentric connected with a ratchet wheel moves the carriage forward about 4 in. for the next stroke of the rabble arm. This motion is repeated until the other end of the furnace is reached, when the machine automatically stops and withdraws the rabble arm from the fire.

Two men, a charger and a helper, operate the furnace. The helper follows close behind the rabble arm and with a long-handled shovel pushes back the loose charge, picking out the gray slag as he goes along. Close behind him comes the charger, who spreads a thin layer of ore on the charge as fast as it is shoveled back, adding coke breeze as needed.

Thus the fire is exposed for an instant only, and by the time the trip down the furnace is completed, the end first charged is ready for the rabbling machine. It is for this reason that the rabbling is performed in one direction only. The first trip being complete and the gray slag removed from the apron, the throwing-in of a clutch causes the carriage to return without rabbling to its original position, where it automatically stops in readiness for a second rabbling trip.

Thus on each trip the fire is rabbled 24 times in 48 sec., the return motion requiring 12 sec. One horsepower is required under full load and is supplied by a 1-hp. alternating-current 220-volt motor. The rabbling machine is simple, strong and durable and only requires a few minutes' attention daily.

From the data compiled it was determined that the hearth could be increased to 8 ft. in length, that it would then produce 2.5 times as much pig lead as the hand hearth, and that two men could operate it with less fatigue than that sustained by two men on the ordinary hand hearth. An 8-ft. hearth was at once constructed, and from the first day of its operation it has not only realized our expectations, but considerably exceeded them.

As direct-hearth labor is paid a certain rate per hundred pounds of pig lead produced, it will be seen that the cost of production, as well as the number of furnaces and number of men employed, has been more than cut in half. Moreover, the hearth laborers can earn more money per shift, through the increased efficiency per square foot of hearth area; and this, in turn, enables us to secure a more desirable class of men.

The following tables show that the 8-ft. furnace gives a much higher extraction of metallic lead, with a corresponding decrease in the amount of dust and fume produced.

Another gratifying feature is the reduction of the fuel added in the form of coke breeze. Whereas the hand hearth uses from 8 to 9% of fuel, the 8-ft. mechanical hearth consumes from 3 to 4%; only it is probable that the decrease in dust and fume, as well as in fuel consumption, is due to the shorter time the fire is exposed after rabbling on the 8-ft. hearth.

It has been found that by pugging the flue dust with a certain cheap chemical and mixing it with a portion of burnt baghouse fume, the mixture can be successfully worked up on the hearth, giving a high lead extraction and a very low percentage of dust and fume.

Thus it will be seen that for galena concentrates of over 68% lead content, the disadvantages of the old-style hearth have been overcome and the cost of production has been lowered to such a degree that sintering with subsequent blast-furnace smelting is no longer comparable therewith.

Smelting Flue Dust on the Hearth

The following is an average of the results obtained by smelting a mixture of pugged flue dust and burnt baghouse fume. This mixture is made up so that the average weight of pig lead produced per shift will be approximately the same as that extracted from 70% galena concentrates.

Owing to the low percentage of sulphur present in the mixture as sulphides, 10% of coke breeze is required.

Burnt baghouse fume, containing 76% and pugged flue dust containing 62% are made into a mixture containing 67% of lead. Of this lead 81.3% passes into pig lead, 10% into gray slag and 8.7% into fume and dust.

The gray slag contains: Pb, 32.4; FeO, 41.7; CaO, 11.1; S, 1.2; and insoluble, 18.7%.

The following table is a comparison of the two types of hearth, operating side by side on the same ore, showing the average results per 8-hr. shift over a period of four weeks, the labor being the same on each type.

COMPARATIVE RESULTS ON NEWNAM AND HAND HEARTH

Ore charged, galena concentrates, containing 72.5% lead, and 15.1 sulphur.

	Newnam Hearth, Lb.	Hand Hearth, Lb.
Dry ore charged	13,179	5,091
Lead contents	9,554	3,691
Pig lead made	6,443	2,030
Gray slag made	3,318	1,329
Per cent of coke breeze used	3 6	8.8
Rabble trips per hour	37 2	....
Percentage of Total Lead in Products		
Pig lead	67 44	55 00
Gray slag	15 18	16 20
Dust and fume	17.38	28 80
	100 00	100 00

Analysis of Gray Slag	Pb	FeO	CaO	S	Insoluble
Newnam hearth	43 7	12 8	9 9	1 9	12 6
Hand hearth	45.0	12 2	9 0	2 6	12.2

The mining costs at these mines are calculated per ton of calamine produced, regardless of tenor in zinc. However, the average content of the concentrates from a mine does not vary greatly. In normal years the total cost per ton of production is from 75 to 105 lire. This cost is segregated and distributed into departments in the manner shown in the following table:

COST OF ORE PRODUCTION

Developments	12-15 lire per ton
Mining	25-35 lire per ton
Ore dressing	13-19 lire per ton
Calcining	6- 9 lire per ton
Transport	4- 7 lire per ton
General expense, royalties, etc.	15-20 lire per ton
Total	75-105 lire per ton
Average	90 lire per ton

The developments usually consist of driving along the mineral zones and crosscutting at intervals to explore for rich calamine masses.

The mining method consists of overhead stoping and filling with waste, which for the most part is sorted in the stopes from the broken ore. Much timbering is often necessary to hold up the ore masses, or pillars of ore are left. For the ore masses that occur near the surface, the ore is mined by large openpits. One of the largest of these open workings is at Monteponi which is 300 m. wide and about 600 m. long and over 100 m. in depth.

The mining is being carried on mostly by hand-drilling, though during the last few years machine drills have been introduced. At certain of the mines practically all the underground work is now being done by machine drills.

The ore dressing consists of a careful sorting on the "piazzale" at the mouths of the tunnels where calamine product, mill ore and waste are made. The hand-sorted product is sent to vertical calcining furnaces, where it is calcined before shipping. The mill ore is sent to the mill, where it is first crushed to under 1-in. size and the size from ½ to 1 in. is jigged. Both the products and tailings from these jigs are hand-sorted by boys. The ore under ½-in. size is concentrated in jigs and on tables. The zinc recovery from the ore treated in the mills is from 50 to 60%, the tailings from the mills averaging from 8 to 12%. The mill product is calcined in revolving furnaces, increasing by about 5% the tenor of the calamine.

From some mines the product is transported to the sea and sent in the smaller boats to the port of Carloforte, at the south end of the island, while from other mines it is delivered to the railway and sent to the port of Cagliari or Portovesme. Thence the ore is shipped to the smelters in Belgium and Germany, although at present shipments are being made to England.

The average tenor of the calamine shipments in 1913 was 40.65% zinc. The average selling value of this product delivered at the ports in Sardinia was about 120 lire a ton.

Future of the Calamine Mines

Although the mining of calamine in Sardinia was begun nearly 50 years ago, only a small portion, relatively, of the mineral zones has been explored. The developments that have been made in recent years have been especially successful, and those mines that have extended their explorations now have sufficient ore reserves for the next 6 to 10 years at their present rate of output, while their tonnage of possible ore is about double that of the reserves. At the Monteponi mine it is claimed that the ore in sight is sufficient for the next 40 years. At this mine practically the entire mountain is being mined as is shown in the photograph. It is therefore probable that the Iglesias mining district will continue producing calamine at its present or an increased rate of output for the next half-century.

The Newnam Hearth*

The smelting of galena in the ore hearth has been practiced in many countries for several hundred years with varying success. In the United States the water-jacketed American hearths and the Jumbo hearths have found some favor in the Missouri lead belt, where large quantities of nonargentiferous galena concentrates are produced.

In form and method of operation the ore hearth has changed but little since its earliest conception. Since its field is restricted to nonargentiferous galena containing over 68% of lead, its use is limited to a few districts; and, on account of certain disadvantages attending its operation, modern sintering and blast-furnace practice have nearly driven it out of the Missouri field.

It is not generally known that the cost of producing pig lead is smaller by the hearth method than by sintering and blast-furnace smelting. Yet it is doubtful if any metallurgist knowing this to be true would recommend an American hearth installation—by reason of the disadvantages which will be briefly enumerated.

Disadvantages of the Ore Hearth

The furnace has been limited to a length of from 4 to 5 ft., requiring for its operation two men working an 8-hr. shift as a maximum. The product per man is small, the work is hot and laborious, and the difficulty of completely removing the dust and fume has made it a notorious source of lead poisoning. Although suitable for operations on a small scale, a large number of hearths would be required for a plant smelting 10,000 tons of 68 to 70% concentrates per month; and the number of semi-skilled laborers would be six times the number of hearths—a condition which is prohibitive.

On account of the high percentage of dust and fume produced, a large flue and baghouse installation is required, and in the past the handling and retreatment of this dust and fume has been a serious problem.

On the other hand, the advantages are the immediate reduction of from 55 to 65% of the lead contents of the concentrates, with simultaneous roasting, thus producing a small tonnage of gray slag, which is an ideal product for the lead blast furnace, since it greatly accelerates the furnace operation and is productive of but little matte, the lead being largely present in the form of sulphate and oxide. As previously observed, the cost per ton of pig lead is somewhat cheaper by this method.[1]

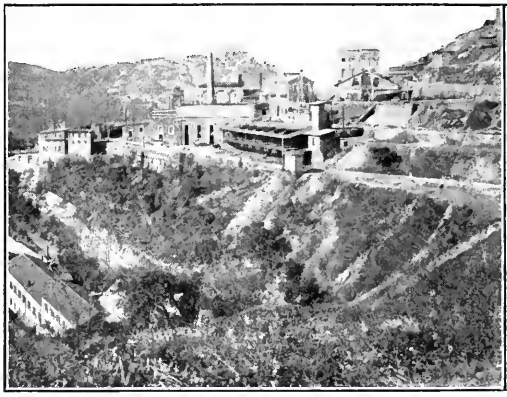
Several attempts have been made to raise the tonnage and reduce the labor on the ore hearths by mechanical means, but up to the present without success. It is the

*Excerpts from a paper by William E. Newnam, to be presented at the February, 1916, meeting of the A. I. M. E.

[1] It may be of interest at this point to note that the lead blast furnace carrying a charge with 20% of gray slag is smelting 7.5 tons of charge per square foot of tuyère area per 24 hr. The lead in this slag is under 1% and the proportion of fixed carbon consumed per charge 7.5%.

The alteration of the original sulphide ores to oxides, carbonates and silicates has probably been due to the action of meteoric waters that circulated along the mineralized calcareous strata, dissolving the sulphides and precipitating the zinc and lead in some as carbonates and silicates. This process has caused but little transfer of the ores. One usually finds some galena with the calamine; and more rarely some blende is present, showing that alteration of the ores has been in place. As gangue mineral, calcites predominate and in some of the orebodies barite and quartz are present. Limonite often occurs in large amounts associated with the calamine; also argillaceous matter where structural disturbances have occurred in the orebodies.

A study of the deposits reveals that after the initial fracturing of the limestones the cementing material along the strata and in the brecciated areas was essentially calcite, while subsequent fracturing was succeeded by the introduction of the calamine and limonite, which also serves as cementing material. Many small seams and masses of limestone in the calamine deposits show a development of calcite adjacent to the limestone walls or included masses, indicating that the deposition of the calcite is anterior to that of the calamine. The finding of these calcite veins and masses in the limestone is usually a good indication of the vicinity of calamine ore. In the calamine masses druses are often present containing small crystals of calcite and occasionally of barite, although such occurrences are later than the calamine. Quartz is of rare occurrence, though the silicate of zinc is usually present with the carbonate, which is the principal ore. The term calamine is applied to the ore, though technically it is essentially smithsonite.



VIEW OF THE MONTEPONI MINE PLANT, SARDINIA

OPENCUT WORKINGS AT THE MONTEPONI MINE

Calamine Sometimes Associated with Lead Ore

Besides the calamine some of the deposits contain lead ore in the form of galena partly altered to cerussite. At certain mines the lead content of the ore is nearly as valuable as the zinc content, while at other mines it is unimportant. Subsequent to the formation of the calamine deposits more or less movement within the mineralized areas occurred, principally parallel to the stratification of the limestones, and caused the development of the argillaceous matter and slickensides that occur frequently.

As to the age of these deposits, it is evident that the fracture zones in which they occur were developed after the limestone strata had been tilted to their present positions. As Devonian strata are interfolded with these Silurian limestones, it follows that the calamine deposits are of post Devonian age. Relatively flat-lying Tertiary strata constitute the next rock formations within the district. As no zinc deposits have been found in these Tertiary beds, they are considered to be of more recent age than the ore deposits.

The ore mined has a zinc content of from 15 to 25%, while an average content of the mineralized zones such as are being mined at Monteponi is from 8 to 12%. At the mines about two-thirds of the production is made by hand sorting, the calamine of which contains from 42 to 48% of zinc, and one-third is produced in the ore-dressing mills, which yield a calamine containing from 30 to 38% zinc. The iron content of the hand-sorted ore is usually from 6 to 8%, while that of the mill product averages from 15 to 30%. Where lead ore occurs with the calamine, as is usually the case, the calamine concentrates often contain from 4 to 8% in lead and the lead concentrates carry as high as 12% in zinc.

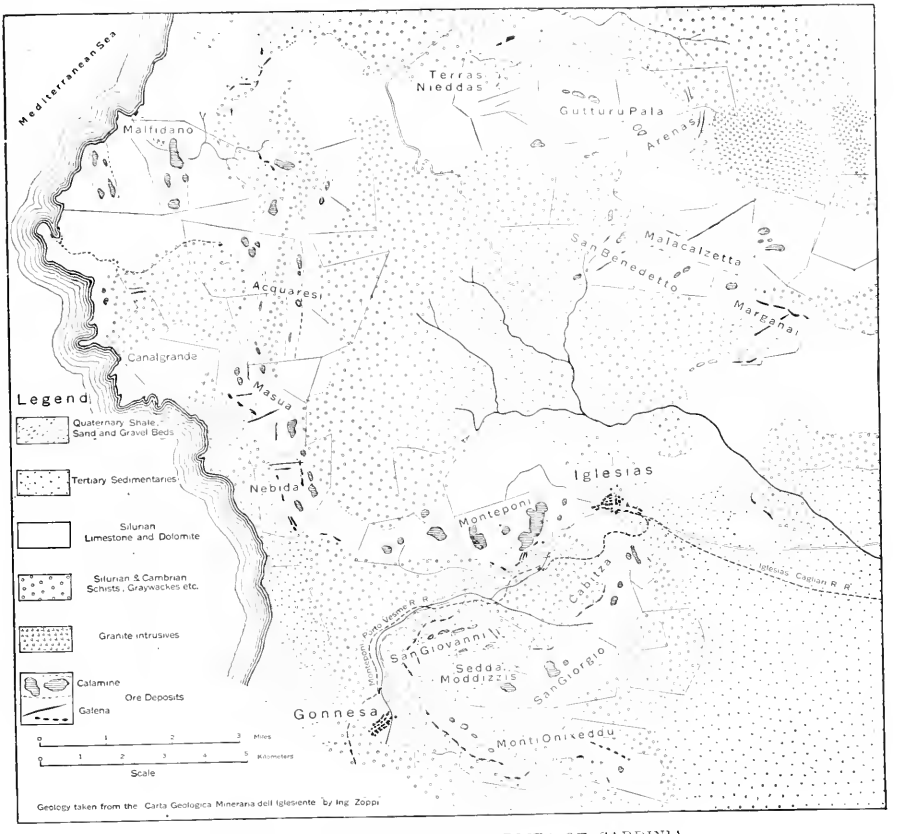
Description of the Mines of the District

The principal calamine mines of the Iglesias district are Monteponi, Buggeru, San Giovanni, Acquaresi, Masua, Nebida and San Benedetto. In normal times the production of each of the first two mines averages from 28,000 to 33,000 tons of calamine annually. The next two produce from 7,000 to 10,000 tons each of calamine and the last three average from 5,000 to 10,000 tons each annually. Besides these there are several small properties that produce from a few hundred to a thousand tons annually. The average annual production for the last 10 years has been approximately 125,000 tons of calamine.

Many of these calamine mines are important producers of lead ore and at the present time it is their lead output that permits them to continue operations at a profit.

In the district there are several important mines that produce lead ores only, and two important producers of blende.

fracturing which are parallel to the structural lines of the inclosing rocks. These mineral-bearing zones vary in width from 20 to 100 meters or more and are often a few kilometers in length. Within the zones the extent of the minable ore deposit is rarely defined by walls of waste and the limits are determined by the amount of calamine present. The ore masses mined are usually from 2 to 20 m. wide and from 10 to 100 m. in length. Usually several important ore masses occur along the same mineral zone and in the same mine. Along orebody. Other deposits consist of a confusion of limestone blocks cemented together by calamine and calcite. An example of such deposits occurs in the area of brecciated limestone and dolomite at the San Giovanni mine, and although these are quite extensive and contain rich ore, locally, they are less regular and less uniform in their zinc content than the Acquaresi type. Another type includes the superficial deposits such as at the Arenas mine, which consist of calamine and limonite ore filling basins in the eroded limestone. These deposits



MAP OF THE LEAD-ZINC DISTRICTS OF SARDINIA

certain of the mineral zones there are two or three mines, and at some of them two or three parallel zones have been developed. In one instance—at Monteponi—the entire mineral zone is being mined by large openpits a few hundred meters in width and several hundred in length.

Ore Deposits in Tilted Limestone Beds

The form of the deposits depends upon the character of fracturing of the limestones within the mineral zones. At the Acquaresi and adjoining mines the limestone beds, although steeply tilted, show but little transverse fracturing or faulting. The calamine occurs in fairly regular veins interstratified in the limestone, and where such veins are found sufficiently close together or are wide enough to be mined separately, they constitute an

are not extensive in depth and are less important than the others.

As to the formation of the ore it is evident that this has been deposited from mineral-bearing waters circulating along the fracture zones in the limestone, and in certain instances the mineral-bearing solutions appear to have dissolved the limestone-inclosing rocks along their course and thus to have formed their own channels and chambers, in which the present ore masses are found.

Originally these ores consisted of veins of sphalerite, pyrite and galena interstratified in the limestones and in masses replacing it. The calamine deposits grade into the sulphide deposits in depth at certain of the mines, while at others masses of calamine ore extend below the lowest levels—in some instances are below sea level.

The Engineering and Mining Journal

Calamine Mines of Sardinia

By Charles W. Wright*

SYNOPSIS—The calamine mines of Sardinia are comparatively recent discoveries in a very old lead-mining district. Mining is by opencut and by overhead stoping and filling. Machine drills have only recently been introduced. Development work presents many possibilities still.

Although Sardinia is one of the oldest lead-silver mining districts in Europe, the value of its large calamine deposits remained unknown until 1865. It was then discovered that the heavy rock that accompanied certain of the lead ores was calamine and that there was a market for it. The development of the known deposits and explorations for new deposits began immediately, and 92,000 tons of calamine was produced in 1870. The output was gradually increased to 127,000 tons in 1900 and since then the annual extraction in the district has varied from 100,000 to 130,000 tons which, valued at the ports in Sardinia, amounts to from 10,000,000 to 15,000,000 lire ($1,930,000 to $2,895,000).

*Mining engineer, Ingurtosu, Sardinia, Italy.

The calamine mines are situated for the most part in the Iglesias mining district, which occupies a mountainous area on the southwest corner of the island.

A small-scale geologic sketch map of a portion of the Iglesias mining district, in which these deposits occur, is added to show the general distribution of the rock formations and the ore deposits. The oldest rocks exposed in the Iglesias district appear to be the Cambrian schists, which contain fossil evidence, principally trilobites, at Canalgrande and in the Iglesias basin at Cabitza and other points. In the limestone beds Silurian fossils have been found at many points, and overlying these, other schist beds occur which are also believed to be of Silurian age. Dolomite in stratified beds and as masses in the limestone is of common occurrence. Overlying the Paleozoic rocks and occupying the lowlands to the south of this mining district are Tertiary beds of sandstone shale and conglomerate. In these, important beds of lignite occur. Still more recent are the lava beds, which in turn overlie these Tertiary beds.

The calamine deposits are confined entirely to the limestone areas, and their occurrence is along zones of

PITTSBURGH—Oct. 5

The resignation of Alva C. Dinkey as president of the Carnegie Steel Co., to become president of the Midvale Steel Co. under its new ownership, astonished the steel trade of Pittsburgh, where it is recognized remarkable financial inducements must have been offered.

Pressure for steel has been increasing still more rapidly. Except in wire products and merchant steel bars there is no question of finishing capacity, the question being simply one of steel supply. Rolling billets are almost unobtainable, and forging billets have sold at fancy prices, even above $40 a ton.

Buyers are specifying very freely on all contracts and in most products the mills entered the fourth quarter with more than half their output specified, and with distinct prospects that specifications on fourth-quarter contracts will bring them to Jan. 1 with specifications for three months' work on books. There is a corresponding disinclination to write first-quarter contracts, though some such business is being done.

Consumptive demand does not appear large, except in relation to the steel supply, and there are many industries that could, in prosperity, consume much more steel than they are taking now. There is therefore a distinct possibility of such a shortage in steel as to cause a runaway market, with prices advancing sharply instead of, as in recent months, at about the rate that obtained in the 1909 and 1912 movements.

Steel bars are up to 1.40c., a level attained last week by shapes, while most mills are quoting plates also at 1.40c. Sheets are up $1 a ton to 2c. Wire products seem on the verge of another advance. Railroad spikes are up $2 a ton for prompt, to 1.60c., and are quoted 1.65c. for first quarter and 1.70c. for second quarter. Shafting is up to 60% discount as minimum, $2 advance in a week and $10 advance on this movement, with the makers practically filled for the remainder of the year.

Pig Iron—The pig-iron market presents a sharp contrast to the steel market. There have been no advances in the past fortnight or more, and present prices are not held with the greatest ease, while actual buying is very light. Consumers are apparently covered for the balance of the year. Sellers expect a general buying movement within about six weeks, for next year's delivery, but the current make appears sufficient for requirements, with quite a number of merchant stacks still idle. Foundry is $14.50 for early delivery and $15 for first half of 1916; malleable is $14.50@15, according to analysis. Bessemer and basic remain at $16 and $15 respectively. W. P. Snyder & Co. announce average prices obtained in September at $15 for basic, a gain of 63.6c. and $15.906 for bessemer, a gain of 84.2c. All prices quoted are f.o.b. Valley furnaces, prices delivered Pittsburgh being 95c. higher.

Ferromanganese—The market is rather quiet, contract material being quoted at $100 for foreign, delivery indefinite, and at $115 for domestic, with delivery assured, and prompt lots ranging between these extremes.

Steel—The market on billets and sheet bars has become nominal. There are no openhearth billets to be had at less than $26, maker's mill, Youngstown, and higher prices have been paid. Sheet bars are nominally $1 higher, while bessemer steel might be had at $1 under openhearth, but it is growing scarcer. Fancy prices are being paid for forging billets, even above $40, with an exceptionally heavy demand, making mills indisposed to quote on rolling billets. Rods are nominally $30, Pittsburgh.

FERRO-ALLOYS

Ferromanganese is quoted at $110@112.50 per ton for domestic 80% material. **Spiegeleisen** has been sold at $27 per ton for 20%, at furnace.—**Ferrosilicon,** 50%, is quoted at $75 per ton at Pittsburgh. Bessemer ferrosilicon is from $20 per ton for 10%, up to $24 for 14%, all at furnace.—**Ferrotitanium** is 8@12½c. per lb., according to size of lots and delivery.—**Ferrovanadium** is $2@2.25 per lb. of contained vanadium.—**Ferrotungsten** is quoted in London at 7s.@7s. 6d. per lb.—$1.68@1.80—for alloy 75@80% tungsten.—**Ferromolybdenum** is quoted in London at 18s.—$4.32—per lb. for 75% alloy.

IRON ORE

Discussion of next season's prices for Lake ore is still going on, in view of the large demand for late shipments. It is generally believed that an advance of 50c. per ton will be asked.

Imports and exports of iron ore in the United States, seven months ended July 31 were, in long tons:

	1914	1915	Changes	
Imports	850,883	671,039	D	179,844
Exports	378,131	252,958	D	125,173

The chief imports this year were 432,845 tons from Cuba, 120,307 tons from Sweden, and 27,008 tons from Spain. Exports were chiefly to Canada.

Imports of manganese ore for the seven months were 163,390 tons in 1914, and 87,136 tons in 1915; decrease, 76,254 tons. Re-exports of imported ore were 28 tons in 1914, and 2,238 tons this year.

COKE

Coke production in the Connellsville region for the week is reported by the "Courier" at 388,884 short tons; shipments, 387,018 tons. Shipments from the Greensburg and Upper Connellsville regions, 45,713 tons.

Connellsville—The contracting movement for furnace coke for 1916 delivery continues, but buyers are showing less eagerness than was expected, and deals are brought to a head slowly. About half a dozen contracts have now been closed, for the first half or all of 1916, involving about 75,000 tons a month. Some of these have been at flat prices, $2.25 and $2.35 respectively, while some operators are still talking $2.50. Other contracts have been closed on a sliding-scale basis, with 20% as much advance for coke as basic pig iron at Valley furnaces may advance, and on such a basis that pig iron at the present market of $15 would mean coke at $2.15; $15.50 pig iron, $2.25 coke and so on. Usually the scale runs down to a minimum of about $1.85, referable to $13.50 pig iron. Contracts now under negotiation are on about the same basis as those already closed. Spot furnace coke has stiffened 5c., being quotable at $1.80@1.85, per net ton at ovens.

Exports and Imports of Fuel in the United States, seven months ended July 31, in long tons:

	Exports		Imports	
	1914	1915	1914	1915
Anthracite	2,211,664	1,997,817	15,902	2,313
Bituminous	9,307,748	10,585,552	758,044	835,222
Coke	408,441	430,604	61,715	24,389
Bunker coal	4,525,876	4,354,037		
Total	16,447,729	17,368,010	835,661	861,924

The bunker coal, or coal furnished to steamships in foreign trade, is practically all bituminous. The greater part of the trade, both exports and imports, is with Canada. There were considerable gains this year in exports to Brazil, Argentina and Italy.

Chemicals

NEW YORK—Oct. 6

The general markets seem inclined to be quieter outside of a few lines, but are rather steady.

Arsenic—Business is still rather slow, but with no change in quotations. Prices are $3.50 per 100 lb. for large lots, and up to $4 per 100 lb. for smaller orders.

Copper Sulphate—Business is steady and sales good for the season. The current quotations are $6.75 per 100 lb. for carload lots and $7 per 100 lb. for smaller parcels.

Nitrate of Soda—The market shows little change and business is fair. The current quotations are 2.42½c. per lb. for spot and 2.45c. for futures.

Pyrites—Imports at Baltimore for the past week included 6,921 tons pyrites from Huelva, Spain.

Imports and Exports of Chemicals in the United States, seven months ended July 31, in pounds:

	Imports		Exports	
	1914	1915	1914	1915
Arsenic	2,609,946	2,291,803		8,825
Bleach	25,554,389	6,181,490	12,654	120,126
Acetate of lime			38,767,339	13,602,955
Calcium carbide			21,351,263	24,732,706
Potash salts	23,041,969	13,562,685	450,302	954,607
Sodium cyanide		3,610,488		1,737,987
Soda salts, value	$380,471	$299,905	$5,542	$22,346

Exports include re-exports of foreign material. This statement does not include nitrate of soda nor crude potash salts used chiefly as fertilizers.

PETROLEUM

The monthly report of the "Oil City Derrick" gives the number of new oil wells completed in September as follows: Pennsylvania grade, 336; Lima-Indiana, 41; Central Ohio, 73; Kentucky, 4; Illinois, 66; Mid-Continent, 371; Texas-Louisiana, 139. The total number of wells completed was 1,030; the total daily production, 101,875 bbl. There were 233 dry holes and 184 gas wells. As compared with August there was a decrease of 16 wells, but an increase of 4,025 bbl in production. On Sept. 30 there were 2,130 wells drilling.

Imports of petroleum from Mexico into the United States in August were 2,039,159 bbl., being 460,512 bbl. more than in July.

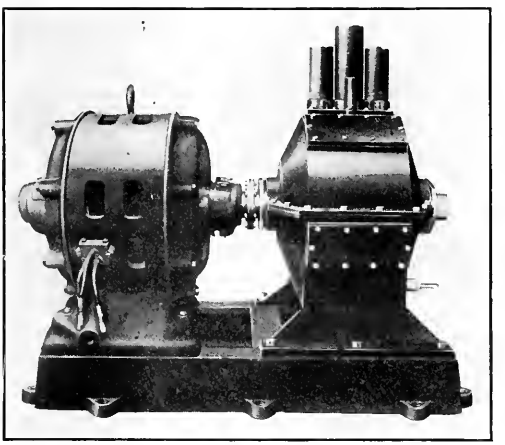
table tops complete with supports and foundation beam should not cost over $50, and to this a royalty of $10 per table must be added for patent rights. A good head motion should be purchased for from $10 to $60, making the cost of the entire table from $130 to $150.

These tables may be built by any good carpenter and blacksmith and the necessary designs and details for constructing and operating them, as well as the permission for their use, may be obtained from the writer.

Jackson Rotary Air Compressor

The Jackson Compressor Co., with office and factory at 1130 12th St., Denver, Colo., has spent about a year and a half perfecting a new type of rotary air compressor. H. O. Jackson was allowed patent for this invention July 16, 1914, his first working model having been completed the preceding February.

The accompanying illustration of the direct-connected motor-driven unit shows this compressor as a small, compact affair. The machine contains no reciprocating parts



JACKSON COMPRESSOR DIRECT-CONNECTED TO A MOTOR

and no valve gearing. Within the member corresponding to a cylinder, ingeniously contrived wings or blades actuated by an eccentric on the central shaft entrap small quantities of free air and these are immediately compressed in a single stage from atmospheric to 100-lb. gage pressure. The volume, or displacement, of each such air compartment is somewhat greater than one-fifth the entire cylinder's volume; hence every revolution of the shaft, with the action of the five compartments, compresses considerably more free air than would be indicated by the cylinder dimensions. Designs and workmanship are so accurate that clearance space is almost nil.

In the size of machine here illustrated the two outer pipes admit outside air to manifolds encircling the cylinder and furnished with poppet-type valves for each of the five chambers between the blades mentioned. The middle pipe is the discharge line, it also having a manifold to receive compressed air through poppet valves from each compressing compartment. These manifolds, as well as the cylinder, are completely inclosed by an outside casing that acts as a water jacket.

Abundant lubrication is effected through an axial hole in the shaft, high-flash oil being distributed by centrifugal action to all interior surfaces, after which it collects in the exhaust manifold and passes into the small drain pipe below, leading to an oil reservoir not included in the picture. The return oil being under the same pressure as the compressed air, a continuous flow is maintained upward from the air-tight reservoir into the shaft, the amount of oil being easily regulated by a simple valve in the line.

Packed Joints Eliminated

There are no packed joints of any sort within the machine, all surfaces being ground to air-tight fits. The compressor runs without noise or vibration. Foundations are unnecessary, the machine being portable in the highest degree. It will operate suspended by a rope with no more perceptible movement or tremor than if it were an electric generator. The intake and expulsion of air is continuous, since several valves are in action simultaneously at every instant of operation. There are, therefore, no noticeable pulsations in either the suction or the exhaust pipes.

The machine will operate equally well running in either direction of rotation, although it is especially designed to work in one direction. Furthermore, it can be used with equal efficiency as a compressor or as a suction pump. In tests for the latter kind of duty, Mr. Jackson states that his vacuum reading has been 22⅝ in. of mercury, which, in Denver, at an altitude of 5,200 ft., is very good.

The speed of revolution of the inner parts can be great. The unit here shown has a cylinder with interior dimensions of 7¾x8¼ in., runs at 1,000 r.p.m., compresses 180 cu.ft. of free air per minute to 100-lb. gage pressure and weighs 345 lb. without the motor. Weights of the Jackson compressors will be about one-tenth the weights of standard piston-displacement machines of equivalent capacities. The consumption of power is slightly less than in reciprocating compressors.

Mr. Jackson has fitted an automobile truck with one of these compressors mounted for exhibition purposes, a silent-chain drive from the engine shaft being provided, whereby the compressor can be thrown into action at any place on the road. He is visiting the mining camps and demonstrating the machine. The company is not yet prepared for or seeking orders, the present purpose being merely to acquaint users of compressors with the invention.

Ten Advantages of Wood Pipe Over Iron or Steel

The Continuous Wire Wound Pipe Co., of San Francisco, in an interesting circular on its new method of winding wood pipe with a continuous wire makes the following 10 claims of superiority for wood over iron pipe:

(1) First cost less; (2) more durable; (3) cheaper to transport and lay; (4) lighter to handle in construction; (5) cheaper to repair and to tap for connecting lines; (6) greater carrying capacity in given size; (7) age has no effect on carrying capacity, except to increase the volume; (8) does not corrode; (9) does not affect the taste of water, and (10) is not affected by electrolysis.

Correspondence and Discussion

Sensitiveness of Frozen Gelatin Dynamites

In an article on explosives, by Percy E. Barbour, which appeared in the *Journal* of Sept. 25, I noticed the following statement: "Unlike 'straight' dynamite, gelatin dynamite is very sensitive to shock when frozen." I have often heard this statement, but never proof for the same.

On p. 29 of *Bull.* 48 of the U. S. Bureau of Mines, also quoted by Mr. Barbour, is an account of some experiments in the detonation of frozen dynamites. The explosives used in these tests were all rated at 40% strength and included "straight" dynamite, ammonia dynamite, low-freezing dynamite and gelatin dynamite; No. 6 electric detonators were used; all the explosives were in a frozen condition, the temperature of experiment varying in different trials from —16° C. to 6° C. In the case of the first three, only one failure to detonate occurred; that being of low-freezing dynamite at the lower temperature mentioned. In the case of the gelatin dynamite, every cartridge failed to explode and in no case was there even a partial detonation.

From a consideration of the foregoing, it seems to me that if we can place any reliance on these experiments, they effectually dispose of the old belief in the sensitiveness of frozen gelatin dynamite.

J. A. Reid.

Kingston, Ont., Oct. 1, 1915.

Making Primers

Referring to an article in your issue dated June 19, 1915, by J. P. Ruth, Jr., entitled "Making Primers," the method he describes by passing the fuse through the dynamite cartridge is bad. It is important that the powder does not become ignited before the detonator explodes, as otherwise an incomplete detonation will result, causing noxious fumes. Although such a system as described can be employed when using electric detonators, it should be avoided with the ordinary burning safety fuse in order to obviate premature ignition of the powder. No part of the fuse should touch the explosive before reaching the detonator.

W. Gérard Boulton.

Valparaiso, Chile, Aug. 17, 1915.

Cost of Winter Construction

The recent contributions of Mr. Curran and Mr. Wood have been interesting. I hope that other builders will contribute their views about the relative cost of construction in summer and winter; that is to say, metallurgical construction. Everybody knows, of course, that the building of a mill, even in the midwinter of a severe climate is feasible. The Hollinger mill at Porcupine was built under such conditions.

I once built a plant in the Rocky Mountains in weather that was below zero—down to minus 30° F.—a good deal of the time. On some days the masons had to quit, owing to the mortar freezing on their trowels. Except for that, however, there was no trouble about the cement and concrete work that was done under cover, as most of it was. In the following summer all the foundations were as true as when they were laid. Not so in the case of some outside work that was exposed to the sun. It is the alternate freezing and thawing that plays the mischief with such work.

So much for quality. As for cost it is a different matter. It stands to reason that workmen who are trying to do their jobs with stiff fingers are not going to do so much as if they were physically comfortable. Mr. Curran is correct in saying that the cost of construction is likely to be very much more in winter than it is in summer.

New York, Sept. 20, 1915.

Technical Journalism and Mining Brokers

The *Journal* of Sept. 4 blossoms out with that old perennial—"The mining broker is a gambler." This diatribe differs from sickliest effusions on the same subject in the *Mining Age, Copper, Curb and Mining Outlook, et al.,* in three ways: Their work is more artistic, the *Journal's* is the more sincere, theirs carries its antidote, slow but deadly, in the advertising columns beside the editorial, while the *Journal's* is rendered innocuous by the painful adage which echoes raucously in the wake of most humanitarian, soul-saving and money-safeguarding sermons and which may be summed up in: "Deeds, not words."

Mining swindles were a prolific source of income for certain satraps of Persia 3,000 years ago, but muleting the public was the legal industry in those days for the man-higher-up. What has the *Journal* done about it in the last six years? In 1909 the *Journal* cleaned an individual cesspool; unfortunately it used an evanescent antiseptic instead of dynamite. That the Augean stables overflow again is proved by its own aforementioned editorial. Permanent sanitation of the mining industry is beyond the strength of any single available Hercules, whether he works with a linotype, typewriter or human gas; yet it is surely within the prerogative and power of our strongest technical journal to lay the foundation for an organized activity which will accomplish the desired result.

Civilized progress, to be permanent, must be based on popular education. A religion may be promulgated with no other motive power than faith; crime, of the purely animal variety, can be hampered by legislation; but protecting the ubiquitous folly of humanity against itself, whether in the matter of typhoid germs or stock certificates, becomes a permanent possibility only when potential sufferers are shown that filth and disease are one, or that the mining broker's much advertised passes to the alms-

house are the most expensive misery with which luxury has ever baited her golden hook. Our engineering fraternity, organized with the assistance of the technical press, possesses the only voice that could effectively instruct the public. It has never tried.

Whence this hitherto insuperable aversion of American mining engineers to strike at an evil that confronts the majority of them in their daily work? To call the body of these honorable men venal—the men who after all are the backbone of the business (to say nothing of the fact that they are *Mining Journal* subscribers)—would be, as far as really useful editorials are concerned, a transfer of the shoe that pinches a small corn, from the left foot to the right, where it would contort the whole foot. This would produce a cramp in the publisher's income tax without ameliorating the condition of that great tribe—the American sucker—whom, in Broad Street, we have always with us. The difficulty lies not in want of good intention or courage among mining engineers, but in lack of organization.

When I am asked to survey, for a consideration, a tract of sand and shingle rock somewhere north of Winnemucca, do I turn down the job because I don't think there's any appreciable quantity of metal (at least in a vertical direction) closer than the molten core that separates us from China? No. My house is glass, yet it's safe if none throw stones save they who be without similar sin. Should the promoter later use my plat as a stock-selling argument, pronouncing me "one of the best-known engineers in the state," do I sue him for libelous exaggeration? No. I hope for the worst because that is the best: May the promoter or broker steal everything in sight within 90 days and drop the venture, for thus will accrue the, in the aggregate, least evil to the least number.

Engineers will always do more or less work on doubtful prospects and their reports, however honest and correct, are always amenable to misinterpretation by stock salesmen because the most hopeless-looking ground may conceal the richest ore. The remedy will lie in the ready availability of an authoritative statement as to the ascertainable condition of any mine or prospect offered to the public.

The essentials of human nature have not altered since the cave-man era. We can expect no diminution in the number of people willing to buy "1,000 shares of Euripides Oil Co. stock for $30," for isn't there "A 33% advance on this oil stock Monday, Sept. 20"? A similar announcement appeared this week in a paper of Joplin, Mo., the most active mining district in the country today. Here we have several large and countless small mines that are working at fair profit for everybody concerned. There's not a live fake broker in the town, although we've had a year's boom in production. The local business community is as firmly set against the prostitution of its mineral as of its human resources; yet, probably because the manager of the Joplin paper does not realize that he is doing for another district what he does not want to see in his own, he spills that six-column stain on his own sheet. Now for the vital question: Has any mining engineer called the attention of that publisher to his mistake? Can readers of the advertisement ask any mining engineer for advice on the Euripides Oil Co.'s prospects for oil and obtain that advice at a price within the reach of a purse opened by the offer of 1,000 shares for $30?

Let an institute of mining engineers organize an information bureau that shall have on file duplicate reports of all work done by the members of that institute. To these reports might be appended a little private mark such as Dun and Bradstreet use, then AA1 will not be set against mining promotions quite as frequently as is at present done in prospectuses. The correspondent system of the *Journal* could be utilized as a skeleton for a network of information agencies responsible to the central bureau. Their work would be far from perfect, but it would be subject to a definite check; gross misuse of the confidence placed in its men would be known to threaten disbarment from connection with any body of approved standing in the professional mining world. The public would at least have a chance to get some of the information it needs. Educational publicity could be promulgated by the bureau, training investors to a clear conception of the hazards as well as the opportunities in mining stocks. Many general newspapers could be brought into line with little trouble, and in time the majority of them. Mining-machinery makers may be persuaded to furnish some of the funds necessary to the campaign, for these manufacturers are vitally interested in seeing investment money go to users of machinery rather than to smudgers of printer's ink.

If we will face the fact, we know that a cloud hangs over our business in the public estimation. This cloud will disappear within 10 years if we but act in unison, and the commercial world will recognize that the greatest, most profitable and safest business, by daylight or candlelight, is mining.

ARTHUR PRILL.

Joplin, Mo., Sept. 10, 1915.

The Situation in Mexico

I have just read in the *Journal* of Sept. 11 some "special correspondence" from Mexico, in which the writer makes a rude criticism on the last decree of Carranza on mining taxes. This criticism I consider unjust, and I wish to give the readers of the *Journal* my own views on this subject.

Formerly the annual taxes on mining properties had been only $3 per hectare (2½ acres). The last decree of Carranza establishes an annual tax of $6 per hectare on a property not over 10 hectares; $7.50 per hectare on what exceeds the 10 hectares and is less than 20; $9 per hectare on that from 20 to 50; and $12 per hectare on all above 50 hectares. This is only an application of the proportional tax to mining property and has been very well received by all single-taxers in this country, and they would see with pleasure these same principles applied soon to rural and city properties. It will promote the subdivision of the property, making the earth available to more individuals, which is the fundamental of prosperity in any country.

At present the mining interests of the Republic, as well as agricultural lands, are in the hands of a few individuals and corporations, which hold large tracts of mineralized lands that they do not develop or explore in the least, only waiting for the opportunity to sell at a high price what has cost them almost nothing. This is not fair. The effect of the new mining tax, we hope, will be to promote the subdivision of the mining properties, forcing landlords to abandon the greater part of their mining

holdings in order to work the rest; and hundreds of prospectors will rush to the freed mineral lands, where we expect to have in the near future many small lively mines working successfully, instead of large dead property producing nothing; and all this will be highly beneficial to the prosperity of mining industry of our country.

Small companies, with hardly enough capital to explore a claim of 1 or 5 hectares, are now holding claims of 20 to 50 hectares, which they cannot develop. The new tax will oblige them to concentrate their attention and efforts over a small area, and the results they obtain will be far better than formerly, while the mining tax they must pay will mean little to them.

To powerful companies working successfully great claims of hundreds of hectares, worth many thousands dollars each, the new tax is of little significance, and it only represents a fraction of 1% of the property's value.

F. ROEL.

Monterey, Mexico, Sept. 25, 1915.

Fettling Reverberatories

Referring to L. D. Ricketts' letter in the *Journal* of Jan. 23, 1915, intimating that Harry Charles, who was employed at Cananea at the time the roof-fettling experiments were being made there, and I were identical, I have not been able to make earlier reply owing to the time necessary to secure evidence of the fact that I was not the Harry Charles referred to, that I was not in Cananea during the period in question, and that I have never been there.

I have recently been in communication with several men who were familiar with my work in Butte and Salt Lake in 1905 and 1906-1907. These men know that I was not working at Cananea during these years, as can be seen from the following quotations from their letters. From Thomas D. Hughes, Tooele, Utah, July 7, 1915:

> In regard to your inquiry about using ore for the lining in the reverberatories at the Montana Ore Purchasing Co.'s plant, it was on No. 4 furnace before I went to Humboldt, Ariz. You experimented on both the stack and the charging; you had a pipe going from the charge floor through which the Snowstorm ore was fed and after we came down to the Bingham Consolidated you fed with the self-feeder. It is "all the go" at all the plants now. In Anaconda they are charging nearly all on the sides; the same at Garfield, and they are doing so well that they are doing away with the blast furnaces.

From the letter of John C. Slater, Midvale, Utah, July 9, 1915:

> In regard to your patent reverberatory feeder, I have not gotten everything clear. After a period of 10 years many things have been forgotten, but I do know that you were intending to put hoppers to use siliceous ores for claying up (fettling) the furnaces at Butte before shutting down there. I also remember that on one of the furnaces—I believe it was No. 3—we cut out a brick from the roof along the side walls, about every 2 ft., and clayed up the sides that way with ore. I do know that while at the Bingham Consolidated we also used a feeder to charge calcine and flue dust continuously in very small quantities but we did not get that completed.
>
> It seems to me that there was some shafting and pulleys or sprocket gearing got ready at Butte for charging but I cannot remember that it was ever put in place. . . .
>
> I remember hearing you say that some day these furnaces would be charged differently, and you were always telling us to keep the ore banked high against the sides and bridgewall, so the charge would be thinner in the center of the furnace. You would say, never mind if the sides are not ready as long as the center is clear so you can skim. If I remember rightly we made two furnaces do what four did when dropping all the charge at the center.

Mr. Hughes and Mr. Slater were the general foremen at the Heinze plant in Butte, 1905-06. They both filled similar positions in 1906-07 at the Bingham Consolidated near Salt Lake City. I could name several others that worked at the Butte plant in 1905, but these two letters will be sufficient to prove who was the first to drop ore around the sides of a reverberatory furnace for fettling and smelting purposes.

In the spring of 1905 at Butte, Mont., while in charge of the Montana Ore Purchasing Co.'s works (Heinze's plant), I drew my first plans of a reverberatory furnace with side hoppers to feed siliceous ores for fettling and smelting purposes. We were treating a very profitable ore from the Snowstorm mine in the converter linings and decided that it would be a good substitute for silica in the reverberatory furnace for fettling. We tried it, but it failed as we could not make it stick to the walls. Later, we cleaned off the bottom in front of the bridge-wall and back angles and made a solid foundation for the ore, which we dropped through the roof. This seemed to hold fairly well, but before proceeding further Mr. Heinze wished me to perfect a continuous feeder that I had had in mind and to patent them both at the same time, since they are capable of being applied simultaneously. Before my plans were worked out Mr. Heinze sold his Montana interests to the Amalgamated and I was instructed to take my plans and adopt them at the Bingham Consolidated plant in the Salt Lake Valley. It was my intention to feed everything at the sides in Butte, but he made me add small charges at the center when we went to Utah.

In the spring of 1906 I started to remodel the reverberatory furnace with the idea of incorporating my feeding and fettling scheme and secured the assistance of W. N. Tanner, of Salt Lake City, now chief construction engineer for the Anaconda company, in preparing the plans and to work out the unfinished mechanical device. It was Mr. Tanner's drawings, based upon my old drawings from Butte, that went forward to prepare the patent application.

In the early days of reverberatory smelting, I was continually trying to figure out how to eliminate the labor and delay incident to fettling. After studying and experimenting with the subject for 20 years, I finally decided on the method of dropping the materials on the side walls instead of trying to throw these materials across the furnace from a small opening on the other side. That always appealed to me as a wasteful method, because it was an exceedingly exhausting task for the men and not more than one in four could place more than 60% of the material where it belonged; furthermore, the furnace became much cooled during this operation and smelting could not be resumed at full speed for some time thereafter.

The inefficiency of the old shoveling method of fettling contributed to an unsatisfactory base for the fettling material to rest upon. I had proved in a small experimental way in Montana that if a satisfactory base were secured, the material could be dropped along the side walls or bridge and made to stick, just as it does on the bottom of the furnace when charged in the old way too rapidly. This led me to the development of the idea of dropping the material along the side walls, and then I also conceived the plans of a more satisfactory distribution of the charge over the furnace, as shown in my earlier drawing at Butte. This drawing shows a bank of ore dropped along the side wall and the tines distributed over the bank and the remainder of the hearth.

At the Bingham Consolidated plant we were not able to apply these ideas exactly as outlined in my patent papers (U. S. Pat. 811,477). I wished to feed practically continuously dropping calcine on siliceous ore and corrode the siliceous-ore bank instead of the brick walls. I also wished to be able to charge anything from the finest material to ores the size of goose eggs, thereby making the reverberatory furnace more efficient than ever before. While many people were skeptical or ridiculed my plan for preventing corrosion of the side walls by dropping material against them instead of trying to throw it across the furnace, it is noteworthy that very few smelters are now attempting to throw their fettling materials across the furnace and thus cooling it down. They have incorporated in their practice my idea of preventing corrosion by dropping the ore against the edges of the hearth.

HENRY L. CHARLES.

La Fundición, Peru, Sept. 6, 1915.

Fineness of Crushing for Assaying

It may be well to preface any discussion of this subject by saying that, while there is an impression that an undetermined, intermediate degree of fineness gives the highest assay results, there is not, so far as I know, any definite information on the subject, such as screen analysis of the sample and slag assays. And it is not positively known whether this is true with all characters of charges, and the exact cause.

We may accept the theory that some of the particles of gold and silver in a sample are so small that they would be held in suspension if not dissolved by the lead, and from this it is safe to assume that the gold and silver must be liberated before the lead has settled, which condition would not obtain in a coarse sample. I am not so sure, however, that the underlying cause is the same for finely ground material, as suggested by Mr. Dewey (*Eng. and Min. Journ.*, Aug. 21, 1915). His premises are none too well taken. It is quite possible that the dusting loss is considerable with finely ground samples, and I have seen cases where this amounted to over 10%. (This is not saying that the sample was properly assayed.) The sample is usually the most infusible constituent of charge, retaining its dry state the longest, with opportunity of being lost with evolved gases.

The effect of boiling is a question which we have been investigating for some time, and find the results are so influenced by contributing conditions that a definite statement is undesirable.

As a single illustration of the difficulty in determining the exact effect of boiling, the following experiment[1] is given:

Jewelers' polishings screened through 150 mesh. The eight charges were fused and cupeled together. The assays for the two different charges were placed alternately in the furnace.

	Charge A	Charge B	No.	Pb Reduced A	Pb Reduced B	Silver, Oz. per Ton A	Silver, Oz. per Ton B
Sample, a.t....	0.2	0.2	1	22.6	21.2	4333.5	4306.0
SiO_2, grams...	5	3	2	21.3	21.3	4337.5	4297.5
Na_2CO_3, grams...	12	15	3	21.5	21.2	4329.0	4313.5
PbO, grams...	50	37	4	22.5	20.6	4316.5	4317.0
$Na_2B_4O_7$, grams...	5	7	Average	22.05	21.08	4329.1	4311.25
Argol, grams...	2	2					

Slag Volume	A	B
Maximum boiling	105 c.c.	45 c.c.
After fusion...	11 c.c.	5 c.c.

[1]Experiment by T. L. Lee, metallurgical student.

The natural inference is that the results substantiate Mr. Dewey's contention, but the slag assays leave the question in darkness. Slags 1A, 2A, 2B, 3B were assayed by adding flux to make them of equal composition, and gave practically the same results: 0.9, 1.0, 0.9, 0.9 mg. silver.

Mr. Dewey's statement in reference to the niter method considers a type of charge which has been largely superseded. The modern high-litharge niter charge boils the least and produces the most fluid slag of any charge we have, and yet is the best for excess reducing ores. It must be admitted that a lead button larger than usual is required[2], but there is no proof that this is necessitated by lack of boiling. It may be a question of relative solubility. We know that slags high in uncombined litharge will contain more silver than where the litharge is satisfied with silica, and we believe that there is an equilibrium between the amount of silver dissolved in any particular slag and the lead button, and that this varies with the ratio of lead to slag. The following illustrates this point: Two slags, from the foregoing experiment, were melted over 10 grams of lead, in compact form, for 30 min. The resulting buttons on cupellation gave 0.56 and 0.80 mg. of silver, while the slag assay of parallel fusions, as previously noted, is 0.92 mg.

These results show a relation to some of those for copper presented by Frank E. Lathe in his interesting article on "Metal Losses in Copper Slags" (*Eng. and Min. Journ.*, Aug. 7, 14 and 21, 1915).

The fallacy in regard to sodium bicarbonate ($NaHCO_3$) dies hard, particularly as there is neither theoretical nor practical evidence in its favor. Bicarbonate when heated decomposes as follows: $2\,NaHCO_3 = Na_2CO_3 + H_2CO_3$, the latter of course being dissociated. As the reaction is to all intents and purposes complete before any fusion takes place, there can be no stirring action except in the dry state, with doubtful advantage. The boiling in a charge is produced by the gases evolved from oxidation of reducing agent and the carbon dioxide (CO_2) displaced from sodium carbonate (Na_2CO_3), which is the same in amount whether the normal or bicarbonate of soda is used, provided they are employed to give equal quantities of sodium oxide (Na_2O).

As practical evidence: In a law case we used normal carbonate for 25 samples from a camp where it was insisted that bicarbonate was essential for the best results. Our results were about 0.25 oz. higher than those obtained by our opponents. The samples contained approximately 25 oz. of silver and had a siliceous gangue. Further, after using the normal carbonate for 10 years, adopted after careful testing with satisfactory results and a saving of 50% in cost of sodium oxide (Na_2O) content, we prefer soda ash to bicarbonate.

New York, Sept. 26, 1915. E. J. HALL.

Assay Charges at Salt Lake

Only a few weeks ago there was a great parade made over the determination of the Government not to compete with the local assayers at Salt Lake City; therefore, if the United States Assay Office would make a charge of $2 per determination. Now we hear that the charge will be $1. How about competition?

Salt Lake City, Oct. 8, 1915. SUBSCRIBER.

NEW PUBLICATIONS

REPORT ON THE SALT DEPOSITS OF CANADA AND THE SALT INDUSTRY. By L. Hebel Cole. Pp. 174, illus. Canadian Department of Mines, Mines Branch, Ottawa.

GUIDEBOOK OF THE WESTERN UNITED STATES. Part D. The Shasta Route and Coast Line. By J. S. Diller and Others. Pp. 142, illus. Bull. 614, U. S. Geological Survey. May be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., at $1 a copy.

GUIDEBOOK OF THE WESTERN UNITED STATES. Part C. The Santa Fé Route with a Side Trip to the Grand Canyon of the Colorado. By N. H. Darton and Others. Pp. 194, illus. Bull. 613, U. S. Geological Survey. It may be obtained from the Superintendent of Documents, Washington, D. C., at $1 a copy.

TRANSACTIONS OF THE AMERICAN ELECTROCHEMICAL SOCIETY, VOL. XXVII. 5½x9, pp. 486, illus. Published at the office of the Secretary, South Bethlehem, Penn.

Contains proceedings of the meeting of April, 1915, together with the papers presented and discussion thereof.

"THE ENGINEER" DIRECTORY. 5¼x8, pp. 176, paper. "The Engineer," 33 Norfolk St., Strand, London, England.

This will be a very useful book to those who are interested in foreign manufacturers of machinery and engineering supplies. It is a classified compilation of the specialties advertised in "The Engineer," the publishers of which issue it gratuitously.

POOR'S MANUAL OF INDUSTRIALS FOR 1915. Sixth annual number. 6x9, pp. cliv + 2872; $7.50. Poor's Manual Co., New York.

The sixth number of this well-known Manual contains about 412 pages more than the 1914 issue. It is impossible to say how many pages are devoted to mining companies as they are not given in a separate section as was formerly done. However, the previous issue had 375 pages devoted to mining, and at the same rate of increase the total number in the present volume is about 435.

As in former issues the volume covers all the important companies, giving complete and accurate information regarding their organization, officers, holdings, earnings, dividends, etc., compiled from official sources. In a volume of this size it is astonishing how nearly up to date it has been brought. Thus, we note certain matters referred to, which happened in mid-August.

MECHANICAL DRAWING. With Special Reference to the Needs of Mining Students. By Joseph Husband. 8½x11, pp. 79, illus., paper; 80c. Longmans, Green & Co., New York.

It is rather interesting to see a book published on mechanical drawing—a so much overwritten subject—with a definite aim. Although the book meets all the essential requirements of general mechanical drawing, containing many examples known to all branches of engineering drawing, the chief value of the book seems to be in the effort to familiarize the student of colliery engineering with all the details with which they are in everyday contact. The language is clear, concise and a well-deserved praise is to be expressed on the legible and neat-looking line-engraving plates—something which is badly lacking in the average publication on this branch of art.

A. L. ORMAY.

UNITED STATES MINING STATUTES ANNOTATED. By J. W. Thompson. 6x9, 1772 pp., cloth; in two parts. Bulletin 94, U. S. Bureau of Mines. For sale by the Superintendent of Documents, Government Printing Office, Washington, D. C., at $2.50 a copy.

This bulletin is a compilation of all sections of the United States Revised Statutes, and of all acts of Congress relating to mines, mineral lands and the mining industry on the public lands. It does not include the state laws, which may be taken up by the Bureau of Mines in the future. References to Alaska and the Philippine Islands are included, and it is the only complete work in its field.

All sections and acts are annotated. These consist of abstracts of decisions of all courts and public officers wherein any of these sections or statutes are explained, construed and applied. The annotations are arranged under each section or statute with appropriate title lines in definite order, and consist of plain propositions of law, and point out how the courts have cured many defects, made clear the uncertainties, and aided in the practical application of these statutes. The large number and wide range of these decisions show that the practical value of the mining laws depends on their present status as established by the courts. The person interested is thus aided in determining the course to pursue in applying any given act to his mining enterprise. The work is indexed and any desired subject may be readily found.

Calumet & Hecla Report

The Calumet & Hecla Mining Co., Calumet, Mich., reports that in 1914 it produced 53,691,562 lb. of copper at a cost of 11.35c. per lb., which it sold at an average of 14.01c. per lb. There was 2,592,462 tons of rock treated, yielding 20.70 lb. of copper per ton. The cost of mining and milling, excluding construction, was $1.85 per ton of rock. The construction cost was equal to 1c. per lb. of copper. The following table gives a comparison of production and costs for the last four years:

	1911	1912	1913	1914
Tons of rock treated	2,909,972	2,806,610	2,035,625	2,592,462
Mine cost per ton of rock, excluding const	$1 84	$1 91	$2 38	$1 185
Pounds of refined copper produced	74,130,977	67,856,429	45,016,890	53,691,562
Pounds of copper per ton of rock	25 47	24 18	22 11	20.70
Cost per pound for construction	0 27c.	0 80c.	1 54c.	1 00c.
Total cost per pound of copper produced	8 52c.	9 86c.	14 25c.	11.35c.
Price per pound received for copper sold	12 82c.	16 65c.	15 77c.	14.01c.

The Conglomerate lode produced 37,996,045 lb. of copper from 1,139,986 tons of rock. The average yield of this rock was 26.38 lb. of copper per ton and the average mine cost, excluding construction, was $2.37 per ton. This copper was produced at a cost of 10.42c. per lb. The following gives the depths of the operating shafts on the Conglomerate lode: Calumet No. 2, 6,186 ft.; Calumet No. 4, 7,995 ft.; Calumet Nos. 5 and 6, 6,155 ft.; slope shaft, 1,588 ft.; Hecla No. 6, 7,874.6 ft.; Hecla No. 7, 7,977.5 ft.; South Hecla No. 8, 6,102 ft., and South Hecla Nos. 9 and 10, 7,930.5 ft. The Osceola lode produced 15,695,517 lb. of copper from 1,152,476 tons of rock, averaging 13.62 lb. net yield of copper. No work was carried on in the Kearsarge lode during the year.

The following table gives a comparison of results at the old recrushing plant (No. 1) and the new crushing plant (No. 8) during the year. Sixteen of the tube mills in the new crushing plant were started during the summer:

	No. 1 Plant	No. 2 Plant	Both Plants
Tons of coarse tailings crushed	351,929	75,630	427,559
Pounds copper per ton in material treated	11 52	11 84	11.58
Pounds of copper saved per ton	3 74	4 59	3 89
Pounds of copper produced	1,316,704	347,363	1,664,067
Cost per pound, excluding smelting and selling	7 38c.	5 66c.	7 02c.

In April, 1915, work was again commenced on a leaching plant to re-treat the tailings from the recrushing plants. At the smeltery the new electrolytic plant is now working to its full capacity of about 65,000,000 lb. of copper per year. Dividends of $1,000,000 paid during the year bring the total dividend disbursement to $124,250,000 at the end of 1914. Cash and quick assets amounted to $1,132,236 and current liabilities to $529,370, leaving a balance of quick assets of $1,134,000. There are further liabilities in the form of 10-year 4% notes dated Feb. 18, 1909, aggregating $1,134,000. The following stocks are owned and not included in the assets stated: 24,512 shares of the Ahmeek Mining Co.; 41,000 shares, Allouez Mining Co.; 11,500 shares, Centennial Copper Mining Co.; 19,400 shares, Cliff Mining Co.; 50,100 shares, Gratiot Mining Co.; 32,910 shares, Isle Royale Copper Co.; 152,977 shares, La Salle Copper Co.; 37,550 shares, Laurium Mining Co.; 32,750 shares, Osceola Consolidated Mining Co.; 11,207 shares, Seneca Mining Co.; 50,100 shares, Superior Copper Co.; 19,400 shares, Tamarack Mining Co.; 42,702 shares, White Pine Copper Co., common; and 15,799 shares, White Pine preferred.

Editorials

Respecting Ore Contracts and Their Failings

Producers of zinc ore are meeting with increasing difficulties in disposing of their product. New producers are in some cases running around vainly in their efforts to find anybody who will take their ore. On the other hand, some smelters are canceling existing contracts that are so loosely drawn as to permit them to find pretexts for doing so.

This is rather unfair, though what is sauce for the goose is no doubt sauce also for the gander. The matter of ore contracts between miners and smelters of ore has been from time immemorial a loose thing in this country. In other minerals it is different. The miner of phosphate rock, for example, contracts to deliver a certain tonnage of known product within a certain period. If he is unable to do it out of his own property he must buy it in the market.

Many years ago attempts were made to get ore contracts upon such a basis, but it was impossible to do this. Ores are quite different in nature from other mineral substances—phosphate rock for example—that are more uniform in character and composition. A buyer may contract for a certain tonnage of phosphate rock guaranteed to exceed a certain percentage of tricalcium phosphate and to be under certain limits of iron and alumina. If he be unable to deliver the stipulated tonnage he can go out into the market to buy it and may have to do so. The producer of lead ore, on the other hand, might be quite unable to duplicate his product. The smelter contracts for a particular thing, not something similar.

Moreover, miners are loath to enter into contracts for specified tonnages of their ore which they may fall short of in the event their mine should unexpectedly and suddenly peter out. These conditions, and others, have bred a looseness in the contractual relation between buyer and seller. The seller delivers what he has agreed to—if he wants to. If he does not want to, some accident happens in his mine; his shaft gets out of order, or by some uncontrollable event it becomes impossible to produce ore. Perhaps it is not deemed necessary to offer any excuse. About 15 years ago the custom of contracting for ore on sliding scale was introduced in the Joplin district. The sellers lived up to their contracts so long as the net yield per ton of ore was above what they could get in the open market. After a few months the condition changed. The sellers then simply broke their contracts. With them it was a case of "Heads, I win; tails, you loose."

The smelter, to meet this attitude of mind, puts in his contracts provisions about impurities in the ore, which enable him to refuse receipt whenever he wants to, always to the great surprise of the miner, who believes he has a real contract. In fact such contracts mean nothing more than the terms of settlement for such business as both parties are willing to do during the stipulated period. This relates especially to business among the small fry. There are some big contracts that are more binding.

The Old Story of Fraudulent Mining Promotions

A correspondent whose communication appears on another page discusses in a breezy way the old question of who should be the guardian of the unwary against the fraudulent promoters of mining stocks. He makes two suggestions that are good in so far as they go, which is only a little way, but are neither novel nor broad-reaching in their practicability. One of them is that the mining journals of good standing should be more energetic in their pursuit of the wildcats; the other is that mining engineers should organize and disbar from the practice of their profession any member found guilty of improper acts.

Now, it is hardly the duty of the engineering journal to act as grand jury and prosecuting attorney in the case of every suspicious promotion. The editors of a paper cannot, even with the assistance of all of their correspondents, become aware of all the schemes that are being put through to inveigle the public; nor can they spare the time and expense to run down more than an occasional one of those that come to their attention. This may be done now and then for an example, for the sake of drawing public attention to an evil, but to expect more than that is unreasonable.

The individual is in a similar position, without owing the responsibility to the public that the journal does. There is not a mining engineer whose eye does not fall often on some advertisement or prospectus that he thinks suspicious—nay, believes to be fraudulent, and would not hesitate so to advise any client that might consult him. But there is great difference between opinion and knowledge. The client that has confidence in the engineer accepts his opinion. The engineer would hardly be justified in communicating to the public any unsolicited opinion, through the medium of the press or otherwise. If he had knowledge of a fraud being perpetrated it might be his duty to expose it. Such exposures are not uncommon.

It is precisely the distinction between knowledge and belief that constitutes the whole difficulty in scotching the fraudulent promoter. If one of that ilk had been advertising a process of extracting gold out of sea water and had been caught in a diving suit putting gold on the submarine plates that he had represented as extracting the precious metal from the brine, there would be no question about his fraudulent intent or his conviction if the officers of the law could lay their hands upon him. The chances are, however, that he would previously have skipped by the light of the moon, just as the Rev. Mr. Jernegan did.

Let another artist appear, however, with an Adirondack gold-mining company or the supposed existence of an orebody beyond a fault; he will, if cornered, maintain that he honestly believed in the things that he had estimated, that he relied upon his "geologists," "engineers," etc., and it is likely to be impossible to prove the contrary.

although everyone experienced in mining may be firm in the conviction that the scheme was fraudulently conceived from the outset. Nobody of intelligence ever was under the illusion that George Graham Rice and Julian Hawthorne ever had any mines of consequence, yet how long and arduous was the adducing of legal proofs in the courts? And even today, Albert Freeman, who pulled the wires that made poor Julian Hawthorne dance, is contesting his conviction on appeal.

It happens on occasion, moreover, that chance may redeem even the baldest kind of a fake. Suppose, for example, that Chicken Bill, of Leadville fame, had promoted a stock company after he had salted the Chrysolite mine, instead of merely selling it to H. A. W. Tabor. The experts would have testified against him to a man, yet his dupes would have forgiven him, as no doubt Mr. Tabor did, and the experts would have been blamed for not being able to look into the ground. The case of the Cananea mines was quite different. There were great outcrops there, great indications of ore, but Colonel Greene, who was a man of the Colonel Sellers type, was hardly justified in making the promises he did. The promotion of his mines through the medium of newspaper broadsides impressed most conservative persons as having all the earmarks of a fake, but the thing made good. Hence the need for caution in summarily condemning some flamboyantly offered enterprises.

The position of mining engineers with respect to fraudulent promotions is perfectly clear. The mining engineer is like other professional men, neither better nor worse. There are shyster lawyers and also there are mining engineers who prostitute themselves. If the public be not discriminating it is the public's own fault. There are organizations—the Institution of Mining and Metallurgy in Great Britain and the Mining and Metallurgical Society in the United States—in which membership means something and whose members would be disciplined if they should transgress.

One other point relates to a clearing house for information about mines. Such information exists in the archives of the several exploration companies and in the files of many mining engineers. There is hardly a mining prospect of promise, besides thousands that are not of promise, about which information cannot be obtained in New York. Such information is often exchanged among engineers. It would be unwise and impracticable to throw it open to the public in the way Mr. Prill suggests.

The eradication of the evil of fraudulent mine promotion is something that can hardly be expected. It has baffled legislators, district attorneys and post-office inspectors. The blue-sky laws enacted in many states are well-meant but humorously ineffective. The actions of the post-office department in closing the channels of the mail and of the Department of Justice in taking chances on conviction where state officials feared to step in have been the most useful things that have been done. There is, however, one relatively easy reform and an important one, namely, a better attitude of the newspapers with regard to their advertising pages. The newspapers that circulate invitations to subscribe to shady and suspicious promotions know that they are aiding and abetting something improper, just as they know it when they are carrying patent-medicine advertisements, and they do it simply for the money it brings them.

Mechanicalizing the Lead Ore Hearth

In a paper just published by the American Institute of Mining Engineers, William E. Newnam, the superintendent of the smelting works of the St. Louis Smelting and Refining Co., at Collinsville, Ill., describes what is manifestly an important improvement in lead smelting in the ore hearth. This method of smelting high-grade ore, relatively simple both in plant and practice, has long been in use in Missouri and at those places in Illinois where Missouri ore is smelted. One of its old drawbacks was eliminated by adding to the smelting furnaces means for the filtration of their smoke—specifically, flues and baghouse—as a result of which the extraction of lead from the ore smelted rose to a high figure, 98% and upward being realized.

This change put smelting in the ore hearth far ahead of smelting in reverberatory furnaces as practiced at Desloge, and also ahead of the roast-reduction, blast-furnace smelting as practiced at Herculaneum. A modernization of the smeltery at Herculaneum kept it in the field, however, the great loss of lead formerly experienced in roasting being reduced, first by the use of the Savelsberg pump and later by the Dwight & Lloyd sinterer.

However, the ore hearth still had the great drawback of extraordinary severity upon the men operating it, they being obliged to work exposed to intense heat, which made their duty well-nigh unbearable in summer, and also exposed to lead fumes in about the worst form. Mr. Newnam succeeded in eliminating both of these difficulties, and incidentally greatly improved the metallurgic results of his furnaces, in fact raising a time-honored type of furnace to an entirely new plane for development. This was an achievement that was worth while.

Terms for Buying Zinc Ores

A correspondent asks about the new method of buying zinc ores that smelters are introducing in the West. We have heard of no new *method*. Any method of buying any ore must necessarily be the value of the metals extractable from it less a sum that will pay costs and leave the buyer a profit. This principle is expressable in a variety of ways. The *terms* for ore are, however, constantly changing, according as market conditions change. The only new terms for buying zinc ore that we have heard of are the fixing of maximum prices; that is, the smelter will not pay for the zinc content at anything above 8c. per lb., no matter what the spelter market may be; or he may agree to pay for only one-third or one-half of the excess over 8c.

Smelters are adopting such a course in order to avoid being stuck with a large stock of high-priced ore when the market collapses, as sooner or later it will. In view of the plethora of zinc-ore supply they are able to dictate their own terms. Two or three years ago, when spelter was very low and certain ores were especially in demand, some contracts for Leadville calamine were made at minimum prices; that is, the spelter of the ore was paid for at a fixed price no matter how much lower the market might be. Even at the present time the best terms are given for calamines. This is for the reason that many smelters have more distilling capacity than roasting capacity.

BY THE WAY

According to the first mining laws of the old Oriental district in Nevada, miners were exempted from annual location work on proving that they had served 15 days in repelling Indian raiders.

⁂

India is ordinarily thought of as one of the diamond-producing countries of the world, but the production of Central India and the Madras Presidency averaged only 45.94 carats per year from 1909 to 1913. The return for each laborer employed was about $7 per year. Rather poor, even for India.

⁂

The *Portland Oregonian* contains the following succinct account of an accident at the Lane County rock quarry, 21 mi. west of Portland: "William Clinton Keever today lighted his pipe, then started to load a hole in a rock with 12 sticks of dynamite. He lived an hour and leaves a wife and four children."

⁂

The *South African Mining Journal* states that the South African Institution of Engineers has passed resolutions offering its services to the British Government in any way in which they can be used to further the interests of the Allies, either in the line of scientific investigation or in mobilizing existing engineering facilities.

⁂

The mystery of the origin of some of the strange market letters on mining stocks that one sometimes sees seems to be explained by the following advertisement in one of the leading financial papers:

WANTED—STENOGRAPHER-STATISTICIAN—Wall Street firm wants services of young man accomplished in stenography, with experience or ability to assist in compiling reports and writing market letters on mines and industrials. State age, experience, salary expected.

⁂

The Grove City correspondence of the Philadelphia *Public Ledger* states: "It was learned here that rich deposits of humus nitrogen estimated at over 4,000,000 tons of raw material, the value of which ranges from $9 to $13 a ton, have been discovered about 2 mi. from the city. Because of the desire to purchase land adjoining that under which the deposit lies much secrecy is being maintained. Samples of the nitrogen brought into this city have been pronounced the finest ever found in this country." We have taken three strikes at expressing our feelings on the varying qualities of nitrogen, but we must leave it up to the readers, after all.

⁂

In describing "Ghost Cities of the West," in the *Saturday Evening Post* of Sept. 4, 1915, Charles E. Van Loan has gone down to Eureka, Nev., which he characterizes as "The Camp of Nine Graveyards." It was a cruel wag from Salt Lake City who said the town of Eureka had graveyards enough to give a decent burial to everything that ever died there, with the single exception of the town itself. Automobilists who plan to drive their cars to the Panama-Pacific International Exposition, by way of the Overland Trail or the Lincoln Highway, will do well to remember that this joke gets more of a laugh in Pioche and Austin than it does in Eureka. When it comes to the subject of death, Eureka is the least little bit sensitive. True, she has nine graveyards, scattered over the low hills that hem in the town—none of them small and some of them more populous than the county seat in its present state—but she sturdily asserts that in her prime she needed them all; for was she not the second largest town in the state of Nevada? Did not Eureka County hold second place in ore production among the counties of a mining state? In the words of one of her prominent citizens—and all the citizens of Eureka County are prominent, one way or another—"The pennant, set at a hundred and twenty-five million dollars, waves unyieldingly on Retention Mountain." The second-place pennant, you understand; the first-place pennant flies on Mount Davidson.

⁂

A careful study of men's fashions has been made by *Engineering and Contracting*, the results of which follow: "Overalls for business wear will remain in vogue at least another season, the most popular shades being sky blue and army brown. There are strong indications that reinforced seats are on the wane. The tendency is plainly to revert to the old-style single-ply effect even though it is less resistant to wear. One regrets that conservatism retards adopting brighter colors for overalls. There is an innate attractiveness, an appeal to the esthetic in the more brilliant hues. Then, too, they often have practical advantages. Leaf-green, for example, is so inconspicuous in the woods and among the tall grass that a foreman clad in overalls of this color may readily come unobserved upon one or more of his gang who are prolonging their vacation beyond all reason. However, leaf green is not insisted upon for evening wear. After 6 p.m. it should be *de rigeur* to don more sedate colors. Dark-maroon pants are a welcome change when worn with a black-velvet waistcoat and a *chic* Stetson hat in one of the mouse grays that are so deservedly popular. Now, a word about the proper buttons to select for overalls. Nothing shows the taste of the well-dressed foreman more clearly than the buttons he chooses. 'Tis a little thing—a button—but much depends on it. The small tin saucers that have served so well for many years are going out. On this point, at least, there can be no question, yet many will regret the change. There was so much that was eminently sensible about the tin-saucer type of overall button. You will recall how readily you could find one if lost in the bunkhouse, even without lighting a match. You had merely to walk around in your bare feet until you felt the sharp circular edges of the tin button pressing deeply into the skin. Then you lifted your foot and removed the button. Also, the old tin button would never split, as do the more beautiful but fragile celluloid substitutes that you must use this fall. A word of caution right here as to the new celluloid buttons for overalls. Considerately handled they are a constant delight. They never rust. They may be had in colors to match the pants, or they may be had in colors that vividly contrast with the pants—just as your personal taste dictates. They depreciate slowly, at least if not brought too near a fire. But avoid scratching a match upon or even near a celluloid button, for celluloid is made, as you may not know, of gun-cotton steeped in nitro-glycerin and then kiln-dried. Clearly, some caution should be exercised by those who adopt this [illegible] styles in overalls and celluloid buttons."

Midvale Steel and Ordnance Co.

William E. Corey, a former president of the United States Steel Corporation, announced on Oct. 6 the details of the formation of a new independent combination of steel companies as follows:

The Midvale Steel and Ordnance Co., organized in Delaware, with an authorized capital stock of $100,000,000, divided into 2,000,000 shares of only one class of the par value of $50 each, today concluded a contract for the purchase of all of the capital stock of Worth Bros. Co., a Pennsylvania corporation, and for all the property and business of the Pennsylvania copartnership trading as the Coatesville Rolling Mill Co.; also for somewhat more than 98% of the capital stock of the Midvale Steel Co., of Pennsylvania, and for all of the capital stock of the Remington Arms Co., of Delaware, which last-named concern has contracted to manufacture 2,000,000 Enfield rifles for the British Government. The company has also under option 300,000,000 tons of iron ore. To acquire the stock and property named and provide working capital, $70,000,000 of the capital stock of the Midvale Steel and Ordnance Co. will be issued.

Neither the Midvale Steel and Ordnance Co. nor the three companies and firm whose capital stocks and properties it is acquiring have any debts other than current and no bonds or mortgages or preferred stock outstanding, and the aggregate working capital of the parent company and its subsidiaries will be in excess of $15,000,000. The money necessary to carry through the transaction has been privately subscribed at par for the stock.

The following are the directors and officers of the Midvale Steel and Ordnance Co.:

Directors—William E. Corey, Albert H. Wiggin, Samuel F. Pryor, Ambrose Monell, Frank A. Vanderlip, Alva C. Dinkey, Samuel M. Vauclain, William P. Barba, Percy A. Rockefeller, Charles H. Sabin, Marcellus Hartley Dodge, and Frederic W. Allen.

Officers—President, William E. Corey; vice-president, Alva C. Dickney; secretary and treasurer, William B. Dickson.

Schwab in New Steel Combine

C. M. Schwab had an all-day conference at the Bethlehem Steel Corporation's office on Oct. 5, with directors of the Pennsylvania R.R., having as its purpose the purchase by Mr. Schwab and his associates of the railroad's controlling interest in the Pennsylvania Steel Co., says the New York *Times*.

On Oct. 12 it was rumored that the Bethlehem Steel Co. did not wish to guarantee the obligations of the smaller companies and that the outcome would be merely a union of the Cambria and Pennsylvania companies. The Pennsylvania Co. owns 51% of the Pennsylvania Steel Co.'s stock and Mr. Schwab desired to take over all of it. The steel company has outstanding $31,200,000 of preferred and common stock and owns all of the stock of the Maryland Steel Co., which has large rolling-mill and blast-furnace capacity at Sparrows Point, Md. More to the point from Mr. Schwab's point of view, the Maryland company has also at Sparrows Point a well-equipped shipyard able to build the largest class of merchant vessel.

Through ownership of all the stock of the Spanish-American Iron Co., the Pennsylvania Steel Co. possesses 52,000 acres of the Mayari ore fields and 17,000 acres of ore lands in the Province of Canay, near Nipe Bay, Cuba. Mayari ores are famous in the industry, the steel made from them being of great value in the manufacture of armor plate and ordnance. This steel is a natural chrome-nickel alloy, and when forged it has from 8,000 to 10,000 lb. per sq.in. more tensile strength and elastic limit than the ordinary carbon steel.

There is reason to believe that control of the Cambria Steel Co. will also pass to the Bethlehem in the near future. The Cambria is also controlled by the Pennsylvania R.R. through the ownership of $22,500,000 of the steel company's $45,000,000 stock, but on this stock an option was given some time ago to W. H. Donner at $50 a share. Mr. Donner is understood to be associated with Henry C. Frick.

The Pennsylvania Steel Co. is made up of three steel- and iron-producing companies and several water, coal and power concerns. The main plant is at Steelton with steel-ingot capacity of 750,000 tons and finished-steel capacity of 500,000 tons a year. Its product in finished lines is diversified, including rails and other railway material, bridgework and many structural forms. Its coal mines turn out more than 700,000 tons a year. The iron-ore properties have produced in the last five years approximately 1,500,000 tons annually.

Reserve Corps of Engineers

The joint committee appointed by the five national engineering societies, the purpose of which was outlined in the *Journal* of Sept. 11, is composed of the following men, each chairman of the committee of his respective society: William Barclay Parsons, A. S. C. E.; Henry S. Drinker, A. I. M. E.; William H. Wiley, A. S. M. E.; Bion J. Arnold, A. I. E. E.; Ralph D. Mershon, A. I. C. E.

This committee, officially known as the Joint Committee of the National Engineering Societies on the National Reserve Corps of Engineers, has selected Mr. Parsons as its chairman and is in communication with the War Department.

A plan is being considered whereby a reserve corps of engineers can be formed, for which, of course, legislation by Congress is necessary, the details of which legislation are now being studied by the War Department. While it has not yet been definitely decided to do so, it is under consideration to issue commissions as officers to such engineers as will meet certain professional and physical standards, and who in times of war would be subject to orders from the Secretary of War as other officers of the army, and in times of peace would perform such duty as would not seriously interfere with ordinary work, but would give each officer some military education and experience. In this way it is hoped to have a large body of engineers that could be called quickly for duty.

The separate committees are still in existence to do the necessary work among their fellow members of the several societies as soon as the decision of the War Department is given and a general scheme of organization adopted.

The members of the committee of the A. I. M. E. on the engineers' reserve-corps movement are: Henry Sturgis Drinker, chairman; Arthur S. Dwight, Warren A. Wilbur.

PERSONALS

J. D. Irving, of New York, is in Butte, Mont., on business.

Ben S. Revett has returned from Colorado to San Francisco.

Henry Krumb and F. S. Schmidt, of Salt Lake City, are in Alaska.

D. C. Bard, of Butte, Mont., has been in British Columbia on business.

L. N. Wagner, formerly operating in California, is in Salt Lake City.

J. Dawson Hawkins, who has been on a holiday to Tahiti, has returned to Denver.

J. A. Van Mater, of New York, has gone to the West on professional business.

H. O. Howard, of San Francisco, is investigating the districts around Lovelock, Nev.

Eugene H. Dawson, of New York, is making examinations in Nevada for Boston interests.

George H. Garrey, who has been in California on examination work, was at Goldfield, Nev., last week.

J. E. Johnson, Jr., will address the Pittsburgh Foundrymen's Association, Oct. 18, on "What Is Good Iron."

C. S. Herzig, of London, is interested in the project to build a seven-mile cable tram to the Alta camp in Utah.

Desaix B. Myers has returned to Los Angeles, Calif., after spending about six weeks in Colorado on professional work.

Kirby Thomas, of New York, has been making examinations in the Rochester and Willard camps, near Lovelock, Nev.

Prof. J. F. Kemp, who has been suffering from overwork, will not take up his academic duties until later in the year.

N. Dickerman, general manager of the Pato Mines (Colombia), Ltd., was in New York last week on his way to the Coast.

Nicholas S. Penn, of the Imperial Institute of Technology, at Tomsk, Siberia, is visiting Grass Valley, Calif., on his way back to Russia..

S. W. Cohen, general manager of the Crown Reserve Co. of Cobalt, is examining a mining property in California, with a view to its purchase by the company.

J. D. Connor, metallurgist for the Government of South Australia, reached San Francisco recently. He will investigate the leaching of copper ores in the United States.

T. B. A. Price, of Boston, has gone to investigate the Rice Lake gold area, in Manitoba, where he expects to make extensive investments if satisfied with the country.

William M. Dailey, private secretary to A. C. Dinkey since 1906, has resigned his connection with the Carnegie Steel Co. and will go with Mr. Dinkey to the Midvale company in the same capacity.

G. C. Bateman, who for the past three years has been connected with the Canadian Mining and Exploration Co., has left that company to accept a position as field engineer for La Rose Consolidated Mines of Cobalt.

M. S. Davys, managing director of the Silverton Mines, Ltd., operating the Hewitt-Lorna Doone group of silver-zinc mines and concentrating mill in Silverton camp, has returned to British Columbia from a business trip to New York..

Edward Hamilton, heretofore assistant general superintendent of the Duquesne works of the Carnegie Steel Co., has been appointed general superintendent to succeed Homer D. Williams, elected president of the company.

W. A. Locke is now resident manager of the Taunton-New Bedford Copper Co., in New York, having succeeded William H. Steele, who held that position for the past 20 years. Mr. Locke has been associated with the sheet-copper business for a period of over 25 years.

Dr. Frank D. Adams, of Montreal, has been in the West, where he and W. J. Dick, mining engineer to the Conservation Commission of Canada, have been investigating deposits of phosphate of lime in the Banff National Park in the Rocky Mountains.

George E. Collins and J. V. N. Dorr have been selected by the Colorado Scientific Society to represent it at the convention in Washington, Dec. 16, to impress upon Congress the need for a revision of the mining laws, which convention is to be held under the auspices of the Mining and Metallurgical Society of America.

Henry M. Rives has resigned the secretaryship of the Nevada Industrial Insurance Commission to accept a similar position with the Nevada Mine Owners' Association. Mr. Rives was formerly with the Pittsburg Silver Peak Gold Mining Co., and a member of the Assembly from Esmeralda County at the last session of the Legislature.

J. P. Keane, who for some years was manager of the Caribou-McKinney mine and mill in Camp McKinney, British Columbia, and later engaged in developing the Wonderful silver-lead mine, near Sandon, was in Victoria recently, endeavoring to make arrangements to lease or purchase a concentrating mill in the Slocan, so that he and his associates might resume the custom ore-concentrating business.

OBITUARY

Dennis Sullivan died at Denver, Colo., Oct. 10. He was well known in New York and had long been a business associate of Grant Schley in British Columbia and Mexican mines. He was a heavy investor in the utilities companies of Henry L. Doherty & Co and in other enterprises.

William Watson died in Boston, Sept. 30, aged 81 years. He was for a number of years an instructor in Harvard University and the Massachusetts Institute of Technology and was an authority on mathematics as applied to engineering; he was also the author of several textbooks. He had been secretary of the American Association of Arts and Sciences for a number of years.

Frank B. Blackmar died on Sept. 29 at the Methodist Episcopal Hospital, Brooklyn, N. Y. He came to New York on Aug. 27 from Puerto Andes, Colombia, where he had been engineer for the Chicago mine, was taken ill on the steamer, and after his arrival was operated on for appendicitis. He received his engineer's degree from the University of Kansas, where he was a member of the Phi Kappa Psi. He was also a member of the American Institute of Mining Engineers.

Isaac B. Hammond died at Portland, Ore., Sept. 23, aged 71 years. He was born in Lambs Corners, New York, but removed to the West in early life, where he had been associated with a number of industries and had much to do with the commercial growth of that part of the country. At the time of his death he was president of the Hammond Manufacturing and Electric Co., which he founded more than 25 years ago. Practically all his life had been devoted to the manufacture of mining and electrical machinery. He was president of the Board of Trade of Portland and active in civic affairs.

SOCIETIES

Mining and Metallurgical Society of America—The New York Section will hold a meeting at the Machinery Club, New York, at 6:30 p.m., on Oct. 19. Woolsey McA. Johnson will make an address on the Lungwitz method of smelting zinc in blast furnaces under pressure.

American Institute of Chemical Engineers—The winter meeting will be held in Baltimore, Md., Jan. 12-15. The date selected is somewhat later than usual because summer meeting was held late in August instead of in June as is customary. Baltimore is the center of a considerable number of important chemical industries. Excursions to a number of these will be arranged. The experimental laboratories of the Johns Hopkins University and the Naval Academy at Annapolis, Md., are also of great interest and will be visited. A number of papers on recent and important developments in some of the chemical industries of the United States are being arranged for.

Rice Lake Mining Association of Manitoba—At a meeting held in Winnipeg, Sept. 29, by those interested in the development of the Rice Lake gold fields of Manitoba, an association under the above name was organized with H. R. McTavish as chairman and J. D. Perrin, secretary. Reports compiled from official records were presented showing that 746 claims are in good standing in the Rice and Gold Lake districts and that some $260,000 has been spent in the country. As there are considerable transportation difficulties to be overcome an effort will be made to receive government help in the construction of a road. A committee was appointed to approach the government with the object of securing an amendment to the Sale of Shares Act so as to permit a mining company to offer stock to the public on its having shown that it has a reasonable prospect of securing mineral in paying quantities.

Editorial Correspondence

SAN FRANCISCO—Oct. 6

Apex Litigation between the Empire and the Golden Center mines at Grass Valley has been settled out of court, upon agreement between the owners. Under the terms of settlement the Golden Center may work all ledges within the disputed area having their apex west of Auburn St., south of Main St., and north of Grass Valley townsite line, with an indefinite western boundary. The Empire may work all ledges apexing east of Auburn St., north of Main St., and south of the townsite line. It is further agreed that each company may work in the grounds of the other when following its own ledges. This will provide for both companies working in the same area, one above the other. This provision is especially advantageous to the Golden Center which is operated by a new company reopening an old mine in the center of the town of Grass Valley. Development brought the operators into Empire ground, which caused the litigation. The settlement is also of great advantage to the Empire mine as it will enable development of orebodies which otherwise might have been contested by the Golden Center. This agreement to take the matter out of the courts, it is hoped, will have some influence in providing for the same kind of settlement between the Empire and the North Star, which litigation is now in the federal courts.

Mining Week at the Panama-Pacific Exposition offered the greatest composite attractions that were presented in any period during the life of the Fair. The chief attraction, not only to mining men but to the visitors generally who have taken some interest in the various exhibits of mining industry, was the Third Annual Field Meet of Mine-Rescue and First-Aid teams. The initial contest on Sept. 22 was the first California First-Aid meet, in which nine teams contested. The Mammoth Copper Co. team won the contest with a score of 374 out of a possible 500. The Mine-Rescue elimination contest, Sept. 23, between three teams from Washington and two teams from Utah, was won by the Utah Fuel Co. with a score of 461.5 and by the Roslyn Fuel Co. by a score of 142. The First-Aid elimination contest on the same date between nine California teams, three Nevada teams, two Utah teams, and three Washington teams was won by the Kennedy Mining and Milling Co. team of California by a score of 491; the Utah Fuel Co., 473; Pacific Coast Coal Co., Washington, 476; Nevada Consolidated Copper Co., 488. The First-Aid interstate contest on Sept. 24 was participated in by 13 teams representing Alaska, Arizona, California, Illinois, Montana, Nevada, Oklahoma, South Dakota, Utah, Washington, West Virginia and Wyoming. The contest was won by the Homestake Mining Co. of South Dakota with a score of 495. The second largest score was by the Nevada Consolidated Copper Co. with a score of 493, and the next the Bunsen Coal Co. of Illinois with a score of 180. The Mine-Rescue interstate contest on Sept. 24 was participated in by seven teams representing Arizona, California, Montana, Nevada, South Dakota, Washington and Utah. The contest was won by the Utah Fuel Co., with a score of 480, the next highest being the Roslyn Fuel Co., 477, and Goldfield Consolidated, 468. The resuscitation contest was participated in by the same teams as were in the First-Aid contest. The contest was tied by the Homestake Mining Co. and the Nevada Consolidated Copper Co. with scores of 100%. The Nevada Consolidated won the tie.

DENVER—Oct. 7

The San Juan National Park, proposed by Enos Mills, is causing considerable discussion and uneasiness in Silverton. It is feared that the park would seriously discourage prospecting and interfere with the development of the county's mineral deposits. Any proposal which would result in hampering mining activity by introducing difficulties in obtaining and maintaining title to mineral lands will be strenuously opposed by the citizens of San Juan County. They will no doubt make every effort to prevent their county from being included in such a national park if there is any likelihood of such embarrassing restrictions as are feared.

Cripple Creek District's Production, which is steadily increasing, during September exceeded the production for August by 5,000 tons, having a gross value of about $48,000, according to estimates. Of the total tonnage—89,800—treated by the various mills and smelteries, the Golden Cycle works at Colorado City handled approximately 48% and the Portland company's three mills, approximately 44%. The American Smelting & Refining Co.'s plants in Denver and Pueblo received about 3,900 tons of an average value per ton of $55. The Portland-Independence mill treats about 10,600 tons of $2 ore per month. October is expected to establish another tonnage record.

Economic Mine Dump is being loaded into cars and shipped at the rate of nearly 400 tons daily. No attempt is made to sort the material. Waste rock at present hoisted through the Gold Coin shaft is also shipped with this dump stuff. At the Elkton mine dump, John Sharpe is ready to start operations with his newly installed plant and expects to handle 200 tons daily. A double-drum steam hoist has been mounted above a receiving bin at highest part of the dump and, by means of drag buckets, will elevate the rock from the lowest portions. Grizzlies, trommels, revolving washers and a sorting belt comprise the equipment below the bin.

Another Nug in the Cresson Mine was opened a short time ago and is sufficiently explored to present a rough estimate of its gross value at about half a million dollars.

BUTTE—Oct. 7

The Socialists Imported an I. W. W., who, according to his own statements, was induced to leave Ireland for the good of Ireland, and last Sunday night they attempted to defy the city and county authorities in Butte and resume last year's interrupted soap-box agitation against all things orderly. The imported agitator and the former Butte socialist mayor were denied the use of the city hall and so they advertised by banners that they would hold an open meeting in front of the hall. The banner bearer was arrested and thrown into jail. He said the ex-mayor had hired him to carry the banner. There was a big crowd on the streets at the hour the ex-mayor and the "importation" were to speak. The former, seeing many officers in the crowd, was a bit diffident about starting anything, but the "importation" nudged him and told him to go ahead. The ex-mayor got so far as to say "Folks," to the crowd, and then the chief of police got hold of his coat collar and one arm and told him to move on. The ex-mayor asked for permission to tell the crowd that he couldn't say anything, but even that was not permitted. Then the socialist ex-mayor and the I. W. W. "importation" headed their followers in a search for a hall, but before they found one they ran up against the county sheriff and a bunch of deputies with "night sticks" and when some of the would-be disturbers got loud they were "nudged" with the sticks, their banners were destroyed, and they were given other evidences of the fact that law and order were triumphant in Butte. When they finally secured a hall a few more than one hundred followers were present to listen. All of which goes to show that Butte, without a socialist administration, is not at all the place it was something like a year ago when the I. W. W. and socialists ran riot, property was dynamited and martial law was brought about in the county.

Local Unions Are Protesting against methods of manual training in Butte Public Schools. How far Butte labor unions can go in their assumed jurisdiction was discussed in a most spirited manner at a meeting held by the Butte school board Oct. 6. A communication from the typographical union in regard to the new printing plant installed in the high school and a report from the school superintendent regarding the position taken by the carpenters' union toward carpenter work being done by the manual training department of the junior high school were submitted. The request of the typographical union that no printing should be done in the school shop outside of regular school work, was granted. The other demand that a practical printer from the union should do the teaching, was held in abeyance, pending the appointment of such a teacher. At the Washington school under the direction of the manual training teacher, boys had been engaged in putting in a partition between two rooms. To this the agent of the carpenters' union objected on the ground that this was work carpenters should do themselves and be paid union wages for. The majority of the school trustees took the position that the work was for the purpose of training the boys in actual carpentry problems

and was not in any sense in competition with the union carpenters. Accordingly the manual-training department was instructed to go ahead and to ignore the demands of the carpenters' union. Whether the latter will take further steps to prevent practical teaching of their trade in Butte schools remains to be seen. Under the rules of the unions, limiting the number of apprentices, boys and girls have no chance of acquiring practical experience and the board held that schools are the proper place for them to receive instruction in these lines of work.

SALT LAKE CITY—Oct. 7

In the New Zinc Camp, in the Lake View Mining District, on the south end of Promontory Mountain, 20 miles west of Ogden, there is considerable activity. Six different properties are operating: The Lakeview, Cedar Ridge, Molman-Smith, Jay Hawks, Corey, and Little Valley. The ore in carload shipments averages about 35% zinc. The Lakeview Co., has paid $12,000 to $15,000 to its five principal stockholders since March. This company produced from the grass roots, so to speak; only $700 to $800 in cash having been expended in development, before it was placed on a producing basis.

SEATTLE—Oct. 6

A Big Shipment of Copper Concentrates from the Beatson Copper Co.'s mine at Latouche, consisting of 2,800 tons, was lost recently when the ore shifted in the hold of the steamer "Edith" and the vessel sank in the Gulf of Alaska. The shipment was valued at $150,000.

Farthest North Camp Yields $690,000 this summer according to the last report brought down from the Koyukuk district. This is an average of $115 per day for the 20 days of the mining season for each man of the 300 operating in that district. The camp lies 140 mi. inside the Arctic Circle and while Koyukuk is extremely rich the difficulties in getting into the district and the high cost of provisions have kept back a stampede. One nugget taken out this summer is valued at over $3,000 while several were taken out averaging $600 apiece. The gold of the camp assays $19.72 to the ounce. Lumber at the camp is worth $600 per M, and during 10½ months of the year there is only on mail. The $690,000 output of the camp last summer is considerably better than the season of 1914 when only $400,000 was produced. The mining season is never longer than 25 days.

First Big Tin-Ore Shipment to the tin smeltery in Seattle will arrive from Buck Creek, Nome district, the first part of November, according to the plans of the American Dredge Building and Construction Co., which installed a new tin dredge there this summer. It now has three machines in the same district, two having operated all season on the Anikovik River. The gravel on Buck Creek contains a large percentage of tin ore and small percentages of gold. The new dredge is equipped with a screen and double flumes, so that no time is lost in cleaning up. A 2-ton truck was shipped up the early part of the year to carry the ore to Nome from the dredge. At the same time a shipment will arrive from Walter W. Johnson of San Francisco who also has a dredge on the same creek from which he took out about 100 tons of tin ore last year. Several small shipments of tin have come down from the North to Seattle before but nothing on a large scale and the results of the smelting will be watched with considerable interest by tin operators in Alaska and the mining interests on the Coast.

DOUGLAS, ARIZ.—Oct. 5

Only a Few Properties Are Working in the northern part of Sonora. The mines at Cananea are working in the smallest way possible as no party has complete control and preparations have been made to close down all the properties should conditions get any worse. Nearly every night the town is entered by bandits connected with neither side and the Chinese stores and small Mexican stores are looted and those who resist are murdered. The Americans and foreigners have armed themselves and are prepared to defend themselves should the bandits attempt to molest foreign properties. Nacozari and El Tigre will be unable to work should the threatened invasion of Villa materialize. Nearly all of the men in both of these camps are Carranzistas and at the approach of the Villa forces they will all retreat to some Carranza base, leaving the mine with none but Americans who are in too small numbers to attempt to operate. At the present time all of the Mexicans within 200 mi. of the border, who are financially able, are bringing their families to Agua Prieta; those who are too poor to send their families out, are going out into the hills where they think that they will not be found by the invading army. Agua Prieta, which is across the border from Douglas, has more people now than it has ever had before and the trains into town are always crowded. There are no houses to be had in Agua Prieta so the people are sleeping in box cars and in the stores. The better class has gone to Douglas and it is now impossible to get a house there. Should Villa come into Sonora it is nearly certain that every mining property will be shut down and as even now there are few provisions to be had of the mining companies Villa would have very hard pickings.

ST. PAUL, MINN.—Oct. 2

State's Income from Iron Properties this year from iron-ore royalties will not be so great as last year. The Leonidas, at Eveleth, will lead the state properties with about 650,000 tons for the season. Based on present explorations the state is assured of an average annual income of $1,000,000 for the next 30 years. Twenty-two state employees are maintained on the Mesabi Range to look after the state's iron-ore royalties, checking operations, tonnages, etc. To Oct. 1 these properties have shipped more than 1,800,000 tons.

BLUE HILL, ME.—Oct. 6

A Large Deposit of Rhodonite at the summit of Blue Hill has been acquired, and is being opened up by C. Vey Holman, formerly state geologist of Maine. This deposit formerly furnished the manganese for the Katahdin Iron Works, Maine's pioneer and only iron blast furnace, which for several decades turned out a considerable output of high-grade charcoal iron. When that furnace went out of blast about 1883, this deposit fell into disuse, and has been practically forgotten. Mining, or rather quarrying, will be simple and cheap, as conditions all conduce to easy handling at low cost. Shipments will be from tidewater at the base of the hill. Analysis of the ore gives SiO_2 43.12%; TiO_2 0.12%; Fe_2O_3 17.53%; MnO, 32.93%; CaO, 3.45%; MgO, 3.48%.

LOVELOCK, NEV.—Oct. 7

A Carload of Antimony Ore from the Sutherland property, at Cole Cañon, 15 mi. northeast of Lovelock, has been recently shipped east by Robert Brown, representative of the Magnolia Metal Co., of New York.

A Small Matting Furnace to treat copper-nickel ores south of Lovelock, near the properties formerly operated by the American Nickel Co., is being planned by W. J. Flick and associates, of Lovelock. The district is about 40 mi. south of the railroad. A small copper furnace on the Boyer mine in that locality is idle but may be started up again. The project for the Southern Pacific to build a cut-off which would make these properties more accessible seems to be suspended for the present.

Tin Ore, Occurring in Veins in Granite, has been found near Battle Mountain, Elko County. Samples analyzed in Los Angeles gave upward of 22% tin. The ore is black and was passed by as iron until very recently. So far most of the discoveries have been in narrow veins, a few inches wide. It is claimed now that a 4-ft. vein has been opened. The deposits lie about 20 mi. north of Battle Mountain. Already 140 locations have been made. Several engineers have visited the district recently, but so far no large interests have taken hold of the prospects, which are controlled by ranch holders in the vicinity. George Russel, Jr., of Battle Mountain, is largely interested in the development of these tin discoveries.

TORONTO—Oct. 9

The Ontario Nickel Commission has completed its investigation of the nickel mines of the Sudbury district, in which it was afforded every facility by the companies interested, who submitted their books and records to a thorough examination. The commissioners will inspect other mines in northern Ontario and will afterwards visit the New Jersey nickel refineries. It is understood that they will make no interim reports and their conclusions are not expected to be made public before many months have elapsed.

The Discovery of Large Nickel Deposits in the Fond du Lac country on the northeast side of Lake Athabasca in Northern Alberta was reported some months since. H. V. Dardier, a prospector who then left for England taking with him samples of the ore with a view of interesting British capitalists has returned in charge of an exploration party sent out by Vickers, Maxim & Co., the noted gun manufacturers of London and Liverpool, who will thoroughly prospect the region. The expedition, which left Edmonton, Alta., for Fond du Lac about three weeks ago, comprises 25 experts, including engineers, mineralogists and assayers and a large force of laborers. Seventeen scows were required for the transportation of their equipment and supplies. The machinery cost $50,000 and the supplies $10,000. The party expect to remain in the district over two years. Their destination was kept secret as long as possible and was not generally known until some time after their departure. The total cost of the enterprise will be about $100,000.

The Mining News

ALASKA

GOLDEN (Port Wells)—Five-stamp mill and other equipment installed by Doctor Chase, of Seward, and associates.

KENSINGTON MINE (Juneau)—Superintendent Rogers and gang of men are doing about 40 days' work, drifting in preparation for more extensive work in spring.

GRANITE MINE (Port Wells)—Graphite mine continues big production. Joe Domenzie, discharged miner, is charged with blowing up powder house at this mine and has been arrested and held for trial. Explosion damaged mill, but no one was injured.

YANKEE BASIN-EAGLE RIVER (Juneau)—Present operating company working Eagle River mine, under management of B. L. Thane, will take over Yankee Basin claims worked by Pete Early and John G. Heid. This will consolidate large properties and require installation of large power plant and driving long tunnel to run to orebody.

MOUNT ANDREW COPPER MINE (Prince of Wales Island)—After being closed down for three years owing to low price of copper this mine has resumed shipping and has just sent 1000 tons of copper ore to Tacoma smeltery. Large quantity of ore is now on hand and company will be regular shipper. W. J. Rogers is manager.

CACHE CREEK DREDGING (McDougall Station)—Is preparing to freight its new 7-cu.ft. bucket gold dredge to Yentna district back of Cook Inlet this winter. It will have a capacity of 3,000 cu.yd. a day and will be first dredge to go into that district. E. L. Smith is president of company. E. E. Todd, of Redding Iron Works, Redding, Calif., is also interested in company. Chas. Harris, formerly of Marysville Dredging Co., Marysville, Calif., is superintendent.

GILPATRICK CLAIMS (Seward)—Development work on this property carried on last summer has resulted so satisfactorily that owners, Gus Brown, Felix Brown, of Seattle, and G. Sieffert, William Dashley and others of Seward will install stamp mill and aërial tramway on property next spring. Several tons of ore recently brought down from property gave return of $102.76 per ton. This was taken from cross vein which cuts main body of gold ore which gives average of $22 per ton. A 10-stamp mill will be installed.

ARIZONA

Gila County

PINAL MOUNTAIN MINING (Globe)—Will begin making regular shipments of gold ore to smelter from its mine, 8 mi. southwest of Globe.

ASBESTOS DEPOSITS (Globe)—Messrs. Fisk and Snell who recently discovered large deposits of asbestos on Ash Creek, 40 mi. from Globe are building mill. They recently made shipment of 4 tons of natural product to Japan.

Mohave County

GOLD REED (Oatman)—Reported splendid showing of ore encountered on 375 level. Milling ore in large body has been opened, alongside of which is found considerable rich material. L. L. Moore is manager.

Yavapai County

HAYDEN DEVELOPMENT (Jerome)—Is erecting 200-ton mill at its Copper Chief mine near Jerome. More than 500,000 tons of ore are said to have been blocked out in mine.

BIG LEDGE DEVELOPMENT (Prescott)—Plans have been adopted by company for erection of mill on its Butternut claims recently purchased. Company has also acquired Henrietta mine which was formerly well-known gold producer. Extensive development to be conducted upon newly acquired properties.

ARIZONA CON. SMELTING (Humboldt)—Smelting capacity will be doubled by addition of new reverberatory furnace, necessitated by increased tonnage from copper mines of De Soto company, which totaled 3,200 tons for August and 4,000 tons for September. Daily swing-train service to Middleton will be inaugurated to handle De Soto tonnage and that from other mines at way station. G. M. Colvocoresses is manager.

CALIFORNIA

Amador County

MARSING (Volcano)—Reported that property will be prospected with diamond drill.

CLINTON BAR (Sutter Creek)—Drifting along channel in progress; prospects of pay gravel.

PINE GROVE (Pine Grove)—Reported that installation of mill is contemplated. Good grade of ore being developed.

Butte County

MANGANESE deposits at Clipper Mills being developed under bond by Noble Electric Steel Co., of San Francisco. Reported that ore will be hauled by autotrucks to Heroult smeltery in Shasta County.

UNDINE (Chico)—D. S. Nesmith, of Boston and San Diego, has secured control and will reopen this gravel property on Butte Creek. Reported that Nesmith will arrange for payment of creditors before purchase payment is made.

Placer County

GOULD (Dutch Flat)—Mineral survey being completed. Owner, J. L. Gould, is one of largest owners of mineral ground in district. Property is developed by 2,200-ft. tunnel that can be made to serve as drainage for Dutch Flat basin. Tunnel has been cleaned out and timbered and car track repaired. Blue lead channel, which has been large producer of gold, is said to cross Gould property.

Plumas County

UNITED STATES EXPLORATION (Quincy)—Development of Granite Basin district on large scale is reported to be contemplated in undertaking of which initial work is being done at Robinson mine where shaft will be deepened 100 ft. during winter. The 20-stamp mill is being dismantled and Sears-Smith rotary mills will be installed with capacity equivalent to 40 stamps.

ENGELS COPPER (Taylorsville)—Survey for narrow-gage railroad from mine in Lights Cañon, through Indian Valley and Indian Creek Cañon to the junction with the Western Pacific Ry. near Keddie is reported to be in progress. Mining company is enlarging its concentrating plant. Electric power line between Butt Valley and mine has been completed and property is now being supplied with electricity. About 200 men are employed at mine.

Siskiyou County

HUMBUG CREEK district is being developed by active operation, including Boyle, Spencer, Summit, High Waters, Ideal, Old Flag and Eliza mines. There are three arrastres in operation and some large cleanups are made. There are several of these mines which were worked in early days when no ore was saved under value of $20 per ton. In the '50s Humbug Creek was known as one of richest producing sections in county.

Tuolumne County

RAWHIDE (Jamestown)—Reported that mine has been sold to men at Blair, Nev., and that new owners contemplate expending about $200,000 in development and remodeling milling plant. Property was originally owned and operated by Captain Nevills, deceased, and is said to have produced several million dollars.

Yuba County

WEST POINT (Camptonville)—Large concrete dam to be constructed for impounding débris and tailings from hydraulic operation.

SOLANO WONDER (Challenge)—Installation of mill and other equipment in progress. Mine is an old producer of high-grade quartz. Present operators giving more attention to medium-grade ore.

COLORADO

Pueblo County

COLORADO FUEL AND IRON (Pueblo)—Has added 250 men to its force in Minnequa steel works at Pueblo making its monthly payroll about $50,000. Rod mill works double time on heavy orders that will require until next spring to fill. President J. F. Welborn states that plant is not filling and will not accept any war orders.

San Juan County

KITTIMAC (Silverton)—New mill nearing completion. Huff electrostatic machine has been installed and management will now add flotation machine. Development work will be resumed in several parts of mine, including west heading on Clark vein.

San Miguel County

TOMBOY (Telluride)—Under management of Exploration Company Ltd., of London, return for month of September shows mill ran 28 days; crushed 13,000 tons of ore, yielding $45,000 bullion; concentrates shipped, $40,500; expenses for period, $56,700, operating profit, $28,800.

Teller County

BLUE BIRD (Altman)—Regular operations by Franklin Leasing Co., which has held this property since last December, are temporarily suspended. Plans are under way for erection of cyanide mill at mine.

PORTLAND-INDEPENDENCE (Victor)—Narrow-gage railroad track that has heretofore been sole access to Independence mine is being rebuilt to standard gage and spurs will be laid to every important building.

ROOSEVELT TUNNEL (Victor)—Total progress during September amounted to 326 ft. On Sept. 20 additional flow of water was encountered in heading of tunnel, in territory owned by Raven and Pearson Hill Gold Mining Co. During few days following, total flow was about 12,500 gal. per min. Breast of tunnel is now about 1170 ft. west of main shaft of Elkton Con. Mining and Milling Co. on southwest slope of Raven Hill.

GOLD SOVEREIGN (Victor)—New shaft will be sunk an additional 200 ft. to total depth of 1525 ft. Work will be performed by Union Leasing Co., which operates property under lease from Gold Sovereign Mining and Tunneling Co., and will be under supervision of C. G. Jackson. Crosscutting and raising operations are in progress and 150 tons of milling ore were produced from development during September. Mine dumps are under lease to Edwin Gaylord, owner and operator of Gaylord mill. Construction of aërial tramway is under consideration, to transport dump material to mill.

IDAHO

Elmore County

BOSTON-IDAHO DREDGING (Featherville)—Operating on Feather River has only worked on small scale this season, owing to lack of water. It is proposed to build 35-mi. ditch to provide more water. Captain Rupert Winters is in charge.

Idaho County

GRANGEVILLE MINE (Elk City)—Under lease and bond to J. J. McKim, H. Cone and Andrew Prader has just completed mill run on ores from 115-ft. level. Results satisfactory. Lessees propose installing compressor. Will carry on extensive development work this winter. There is a 5-stamp mill on property; several hundred tons of ore have been mined and milled since first of year.

MINERAL ZONE (Elk City)—Work on removal of 3-stamp mill from Elk City Reduction Co.'s plant to this property is nearly completed and erection of mill on new site is well under way.

Shoshone County

GUELPH (Wallace)—A 200-ft. shaft will be sunk on this property, which lies north of Hercules. Compressor has been installed and hoist ordered.

EAST CALEDONIA (Wardner)—Has made promising strike in drift on 200 level, where two shifts are driving. Mine has recently been cleaned of debt and is said to be in shape financially for considerable further development.

KILL BUCK (Wallace)—Constructing electric-power line to compressor at portal of Vulcan tunnel and will start driving for Kill Buck vein as soon as power is available. Vulcan tunnel is in 3500 ft. and has about 400 ft. to go to reach vein.

IMPERIAL (Wallace)—Directors of this company have inspected mine and announce that work will be resumed. Winze will be sunk on promising oreshoot in upper tunnel and crosscut will be driven from lower tunnel to prospect body of ore discovered by diamond drilling.

COPPER PRINCE M. & M. CO. (Wallace)—Capital stock of this company has been reduced from 4,000,000 shares to 400,000, par value $1. On Copper Prince claim winze is sinking from 500-ft. adit. On Gold Ridge claim three crosscuts show ore in vein. Property is equipped with compressor and air drills. Samuel B. Holbert is president and general manager.

FRISCO (Wallace)—This mine, now owned by Federal M. and S. Co., has been started up after short shut-down for purpose of making alterations in mill. Mine was reopened to recover zinc ore left in old workings but exploration at depth has proved large quantities of ore carrying lead and zinc. Owing to difficulty of separating lead and zinc, recovery at 400-ton mill has never been satisfactory.

MICHIGAN

Copper

ESTIMATED PRODUCTION OF LAKE SUPERIOR COPPER MINES for the month of September, based on rock tonnage and known averages of refined copper is as follows: Tamarack, 561,600 lb.; Osceola Consolidated, 1,755,000; Ahmeek, 2,225,000; Wolverine, 711,000; Mohawk, 1,359,000; Franklin, 381,600; Centennial, 53,000; Allouez, 818,000; Mass, 486,000; Superior, 326,000; Hancock, 159,800; La Salle, 177,000; South Lake, 21,600; Isle Royale, 900,000; Copper Range Consolidated, 4,600,000; Quincy, 2,000,000; Calumet & Hecla, 6,500,000; White Pine, 491,000; Lake, 280,000; Winona, 220,000.

WHITE PINE EXTENSION (White Pine)—Management, both in Michigan and in east, will be in hands of Stanton interests who became associated with Smith interests some months ago. Frank Stanton will arrive in few days to visit other mines of Stanton interests in this district and likewise to go over work already done at White Pine Extension and to map out plans for future.

OSCEOLA CONSOLIDATED (Osceola)—Average rock for all mines in this corporation for September ran close to 14 lb. Old Osceola shipped 24,000 tons and Kearsarge branches 99,000. No. 3 shaft, old mine, goes into commission this week, adding to low-grade rock tonnage. Shaft has been repaired and cleaned down to 8th level. Rockhouse equipment is permanent and in good condition

Iron

OHIO (Michigamme)—Small pile of ore that has been in stock for years is now being shipped. No mining is being done.

MINNESOTA

Mesabi Range

WEBB (Hibbing)—Mine will be reopened within few days. Has been idle for two years. Mining will continue all winter. It is large underground property. Employs between 400 and 500 men when working full force.

LA RUE (Nashwauk)—M. A. Hanna Co. has reopened this mine. One hundred men have been given employment. One shovel is working two shifts. Pipe line five miles in length is being built from O'Brien Lake to the washing plant. Fifty cars of ore will be shipped daily until end of season.

QUINN-HARRISON (Nashwauk)—Five shovels and three merry-go-rounds are working days in pits. All five shovels are working nights. Rapid progress is being made with stripping. Washing plant is now working one shift. About 30 cars of wash ore are shipped daily. About 85 cars of merchantable ore are going direct from pit. Machine shop 200x50 ft. is to be erected. An addition is being made to office.

Missouri—Kansas

VAN BIBBER & CO. (Joplin, Mo.)—Has made strike on Block City land, west of Joplin. Encountered run at 127-ft. level, and now has 12-ft. face of 15% ore and is still sinking in good ore.

JUMBO MINING (Alba, Mo.)—Fire of unknown origin destroyed concentrating plant of Company northeast of Alba. Cost of plant $25,000; insurance about $7,500. Property owned by Carthage men. Mill had been running about 1½ years.

STANLEY MINES (Galena, Kan.)—John McLaren and associates have taken lease of 40 acres on what is known as Stanley mines, and are installing pumps and 60-hp gas engine. Expect to have machinery in place in about three weeks and have water out in from six to eight weeks. This tract of land was formerly owned by Ex-Vice-President Adlai Stephenson, of Bloomington, Ill. Was formerly large producer, but has been idle for several years.

MONTANA

Silver Bow County

ANACONDA (Butte)—Has completed installation of surface plant at Emma mine, of Butte Copper and Zinc Co., taken over under lease and bond recently. Pumping will be started in few days and as soon as water is out of mine sinking and mining will be started.

BUTTE & LONDON (Butte)—Cole-Congdon interests are also about to start sinking in Butte & London; big electric pump having been installed at station on 1,100. Water is practically all out of mine, and sinking will be started at once to depth of 1,600 ft., at which point entire ground of company will be crosscut and explored both north and south.

RAINBOW DEVELOPMENT (Butte)—Shaft has reached depth of more than 1,450 ft., and station will be cut at 1,500. After station and sump are completed company will crosscut to big Rainbow lead, according to present intentions. It is anticipated that ore will be found in vein at that depth, but if it is not of commercial character shaft will be sunk deeper.

DAVIS-DALY (Butte)—Is developing Hesperus vein, which has been opened on 2,500-ft. level distance of 150 ft. In all that distance vein is about 12 ft. wide, containing 1½ to 5 ft. of commercial ore well sprinkled with copper glance, bringing average grade up to 5½% copper. Colorado is so poorly ventilated that work on 2,500 level is slow. New orebody has appearance of permanency.

NEVADA

Clark County

BULLION (Goodsprings)—New dry-concentrating plant has been in operation for last few weeks, successfully treating low-grade lead ore. Plant has a capacity of 50 tons per day and uses Stebbins dry-concentrating tables.

ANCHOR (Goodsprings)—New dry-concentrating mill is nearing completion. R. W. Moore is in charge of property. Mill was designed and erected by Ore Concentrator, of Los Angeles. Plant will use crusher, rolls and Stebbins' tables, and will be of 50-tons capacity.

YELLOW PINE (Goodsprings)—Mill is operating two shifts daily, producing full contractual allowance of 1,500 tons zinc-carbonate ore monthly, also 200 tons of lead concentrate. A dividend of 1c. per share, amounting to a total of $100,000, has been declared, making total of $230,000 paid by this company during current year.

Esmeralda County

CHAMP DOR FRENCH GOLD (Hornsilver)—William Dunphy lease on Orleans group now shipping 25 tons of $35 ore per day. Haul 16 mi. to railroad is done by autotrucks at contract price of 20c. per ton-mile.

GOLDFIELD CON. (Goldfield)—Estimated production for month of September, 1915, is: Total tons mined, 32,500; gross extraction, $269,000, operating expense, $159,000; net realization, $110,000.

JUMBO EX. (Goldfield)—Production approximately 80 tons of $45 ore per day. No. 2 shaft, a 4th compartment shaft on the Velvet claim, projected to 1,000-ft. level to facilitate operations in present workings and development of northern portion of ground, now down 525 ft.

Nye County

TONOPAH ORE PRODUCTION for week ended Oct. 2 amounted to 9,496 tons, valued at $196,888, compared to 9,629 tons week previous. Producers were Tonopah Belmont, 2,756 tons; Tonopah Mining, 2,800; Tonopah Extension, 1,850; West End, 851; Jim Butler, 1,100; and miscellaneous leasers 139 tons.

ROUND MOUNTAIN MINING (Round Mountain)—Hydraulicking suspended Sept. 1 on account of lack of water. Now cleaning bedrock and preparing races for next season's run, which begins about March. Cleanup so far indicates value of about $2 per yd. for gravel handled this season.

Storey County

COMSTOCK PUMPING ASSN. (Virginia)—Repairing and equipping main south drift from Ophir-Mexican winze on 2,700 level.

UNION CON. (Virginia)—Saved from No. 1 stope north drift 36 cars of ore, averaging $17.10 per ton; from No. 2 stope southwest drift, 8 cars, averaging $15.73 per ton; from stope No. 3, near Sierra Nevada line, 86 cars, assaying $21.67 per ton.

MEXICAN (Virginia)—On 2,500 level started southwest drift from south drift No. 3, showing 3 ft. of quartz of low assay. East crosscut No. 3, 2,700 level, shows porphyry and stringers of quartz. Mill crushed 248 tons of ore, assaying $9.66 per ton

CROWN POINT-BELCHER (Gold Hill)—Water 6 ft. below 1,600 station of joint incline; 1,600 level drained, repairs started in east crosscut. Saved 11 cars mill rock from Belcher 1,300 raise. Jacket mill received 966 tons of dump rock.

CON. VIRGINIA AND OPHIR (Virginia)—Equipment and winze between 2,500 and 2,700 levels completed. Small station cut on 2,700 level for starting west crosscut. Ophir discontinued raise on vein from 2,500 level southwest drift; prospecting vein below sill floor. Central mine extended north drift on 2,500 level distance of 12 ft., 5 ft. of quartz assaying $5 to $11 per ton. Extracted 21 cars of ore and milled 220 tons.

NEW MEXICO

Grant County

HARDSCRABBLE (Pinos Altos)—Lease has been granted on property and several shafts will be opened up. Property has been offered for sale.

EMPIRE ZINC (Hanover)—Company has practically completed erection and installation of machinery at new powerhouse. Will generate electricity for mines and mill soon to be constructed.

85 MINING (Lordsburg)—Company has bought Atwood mine from Atwood Copper Co. Consideration reported in neighborhood of $100,000. Diamond-drill work now being done on Atwood. The 85 Mining Company now controls most important property in Virginia District. During month of September 232 carloads of ore were shipped from camp.

Lincoln County

ROBERTS MINES (Oscura)—Mines of D. W. Roberts have been leased to A. Chavez. Leaser has commenced work on property.

NAYLOR MINES (Tularosa)—Bismuth is being mined in San Andres mountains by Joe Naylor. Payment of 75c. per lb being received.

Luna County

ROYAL JOHN MINING CO. (Deming)—Company has filed articles of incorporation. J. C. Watson, agent. Capital $250,000. Mines are at Lake Valley, N. M.

AMERICAN SPELTER CO. (Deming)—Company is being incorporated by J. S. Vaught and D. S. Robins, of Deming, N. M. Will do general mining and milling.

SADDLER MINE (Cook's Peak)—Messrs. Hohlmeyer and Gunther, of El Paso, have bought mine from G. M. Sadler and W. O. Grace. Zinc ore will be shipped to Oklahoma from Spaulding Siding.

Santa Fé County

SANTA FE GOLD AND COPPER (San Pedro)—Company produced 289,766 lb. copper in August. $74,130 profits reported for past quarter.

Taos County

MEMPHIS RED RIVER MINING (Red River)—Mill and machinery of Trinidad Mine and Milling Co. acquired by company. Plant being put in condition for operation.

TEXAS

Culberson County

GEORGE A. PLUMMER (Port Arthur)—Plans to install large plant for extracting and refining sulphur from big deposit situated in northern part of Culberson County. Proposed improvements will cost about $370,000, it is stated.

UTAH

Beaver County

CREOLE MINING (Milford)—Articles of incorporation for this company were filed Oct 4. Capitalization is 1,000,000 shares, par value 10c. on 600,000 shares issued. Norman W. Maire is president. Several hundred tons of copper ore are said to be exposed. Further development and shipments are to be started in near future.

Juab County

TINTIC ORE PRODUCTION for month of September amounted to 506 carloads, estimated at 25,300 tons, valued at $830,000. This compares with 648 carloads in August and 817 in July. The producers for month of September, 27 in number, were as follows: Chief Consolidated, 107 cars; Iron Blossom, 78 cars; Centennial Eureka, 78 cars; Mammoth, 52 cars; Eagle & Blue Bell, 48 cars; Gemini, 29 cars; Grand Central, 17 cars; Dragon Consolidated, 16 cars; Gold Chain, 11 cars; May Day, 11 cars; Beck Tunnel, 11 cars; Sioux mill dump, 10 cars; Victoria, 7 cars; Lower Mammoth, 6 cars; Beck Tunnel, 6 cars; Colorado, 3 cars; Carisa lease, 3 cars; Uncle Sam, 3 cars; Minnie Moore lease, 2 cars; Opohongro, 1 car; Eureka Hill, 1 car; Ridge & Valley, 1 car; Tintic Standard, 1 car; Utah Consolidated lease, 1 car; Cliff lease, 1 car; Utah Mining concentrates, 1 car; Utah ore sampler, 1 car.

KNIGHT-DERN MILL (Silver City)—It is understood that this plant will treat large tailings dump at Eureka Hill.

RIDGE & VALLEY (Eureka)—Since lowering of water level to 1,700, work has been done between that level and 1,600. Ore carries lead, silver, copper and gold. On 1,600 and 1,500 levels development work is being done toward north.

GEMINI (Eureka)—Leasers shipped 150 tons of ore in September. New work is being done on company account on lower levels, where water has recently been lowered to 1,700 level. This will allow development of orebodies, opened some time ago, and later covered by water.

CHIEF CONSOLIDATED (Eureka)—Good progress is being made in building new wagon-road between Scotia mine under lease and bond to this company, and loading station at Jericho on S. P. L. A. & S. L. R.R. Ore will be hauled by traction engine, capacity being 15 tons per trip.

Salt Lake City

UTAH COPPER (Bingham)—The August production was the largest in the history of the company, amounting to 15,966,543 lb.; 9 steam shovels are being worked on ore, and 11 shovels on stripping and waste; 30,000 tons of ore are being mined daily, and the shovels on waste are handling more material proportionally, per shovel.

Summit County

PARK CITY ORE PRODUCTION for month of September amounted to 7,835 tons, valued at $313,400. Shipments made by the principal mines in September were as follows, according to weekly shipment records: Silver King Coalition, 2,960 tons; Daly-Judge, 2,000 tons; Silver King Consolidated, 1,323 tons; Daly West, 945 tons. Ontario, 52 tons; D. W. Quincy, 45 tons; others (estimated) 500 tons.

NAILDRIVER (Park City)—Work is to be started at this property in eastern part of camp.

WISCONSIN

Ashland County

SOO LINE (Ashland)—New concrete-steel dock is to be erected at Ashland, to replace wooden structure that is in bad shape. Work will be started as soon as navigation closes. It will cost about $3,000,000 and will be one of largest docks at the head of Lake Superior. Old dock will be torn down. Work will be rushed with all possible speed in order that there will be no loss of time in spring. Soo line will handle over 1,000,000 tons from Gogebic range this year.

Zinc-Lead District

VINEGAR HILL ZINC (Platteville)—Site has been staked out for new mill equipment on Graham land at Millbrig.

FRONTIER (Galena, Ill.)—This company has started shaft sinking and will assemble Baxter mill equipment on the Treganza property just west of Benton.

UTT-THORNE (Platteville)—Rich strike of high-grade zinc ore has been made by churn drill ahead of Lawrence mine on Lawrence land northeast of Cuba City.

WISCONSIN ZINC CO. (Platteville)—Steel construction work on new 75x100 roaster at New Diggings has been completed. Skinner type of roaster and Cleveland-Knowles separating machines will be used. Shaft sinking has been begun on C. A. Thompson land and shafts will be started soon on Longhorn and Birkbeck leases which have been proven by churn drill.

CANADA

British Columbia

RAMBLER-CARIBOO (Three Forks)—After suspension of payment for about 12 years, will resume dividend disbursements Oct. 15, when 1c. per share will be distributed. Second payment of equal amount will be made Dec. 15. Total of two payments will be $38,500.

Ontario

DOME (South Porcupine)—Monthly statement for September shows bullion production of approximately $139,000 making new high record. Tonnage treated was 28,500 of average value of $4.87 per ton.

DOMINION REDUCTION (Boston Creek)—This company is operating property adjoining Papapassmakes claims, on which there is an orebody 10 to 15 ft. wide in places carrying low gold content. Putting down a 200-ft. shaft.

KENZIE (Boston Creek)—This property, one of claims controlled by John Papapassmakes, has been worked all season. Vein having paystreak 12 in. wide rich in free gold is being developed. It has been stripped for 450 ft. and two shafts are being put down.

MUNRO CONSOLIDATED (Munro Township)—This company recently organized owns six claims, operations on which are in charge of George Leyson. Sinking has been begun on vein carrying free gold, which was 4 in. wide at surface and at 70-ft. level had widened to 14 in.

HOLLINGER (Timmins)—Regular 4-weekly statement for period ended Sept. 9 shows gross profits of $149,936 from treatment of 28,172 tons of ore of average value of $9.03 per ton. Working costs $3.17 per ton. Mill also treated 11,559 tons ore from Acme mine. Total surplus on hand was $1,331,461.

Quebec

A DISCOVERY OF MOLYBDENUM is reported by J. D. Kennedy, of Sherbrooke, Que., on the river Metabetchasuan, near Chambord. The property is crossed by the Canadian Northern Ry. and offers good facilities for transportation.

CANADIAN CHINA CLAY (Huberdeau)—Kaolin property and plant at Huberdeau have been closed down for winter. It is expected that railway will be built to property by spring and in meantime additions and alterations will be made to plant to permit of steady output.

MEXICO

Sonora

THE ORE SHIPPED FROM MEXICO through the port of Agua Prieta for the month of September was as follows; from Nacozari, 7,736 tons; Montecristo, 22; La Caridad, 24; La Bellota, 101; Minnesota, 111; Crestoncita, 31; San Ygnacio, 55; Archipelago, 14; Belen, 22; Silver Snake, 23; Cobre Parado, 36; Palacio de Hierro, 18; Los Metalles, 16; Maria, 5; Santa Maria, 32; Rosario, 6; Mexico, 37; San Pablo, 50; La Coqueta, 68; San Jose, 47; Esperanza, 20; La Cruz, 14; El Tigre, 257. Total, 8545 tons. El Tigre also shipped 100 sacks of silver and gold precipitates weighing 19,459 lb. and 99 bars of silver and gold bullion weighing 18,205 lb. Estimated value of shipments in Mexican gold, or at the rate of 2 for 1 American dollar is, copper, $1,176,500; silver, $410,800; gold, $264,300; total, $2,551,600.

MONTECRISTO SONORA MINING (Moctezuma)—Thirty tons of ore that will average nearly 300 oz. silver have been shipped to Douglas smelters.

ARCHIPELAGO (Cumpas)—Three feet of 15% copper ore have been exposed in cleaning up old workings and men are now at work breaking ore. About three tons daily are being shipped from mine and dump.

NACOZARI CONSOLIDATED COPPER (Nacozari)—New body of ore has been encountered in what is thought to be ancient Spanish workings. Ore is silver glance and native silver. First car of concentrates shipped since railroad has been re-opened between Nacozari and Douglas netted $2,356.

AFRICA

Rhodesia

THE GOLD OUTPUT OF RHODESIA in August was $2,545 oz., being 1,876 oz. more than in July. This brings the production for the eight months ended Aug. 31 up to a total of 601,954 oz. or $12,442,389. Other production in August was 16,830 oz. silver, 321 tons copper, 3 tons lead, 26 tons asbestos, 4,271 tons chrome ore and 38,143 tons coal.

The Market Report

Metal Markets

NEW YORK—Oct. 13

All of the principal markets were quiet during the last week without material change in prices. Copper and spelter exhibited drooping tendencies, while lead was a little stronger in tone.

Copper, Tin, Lead and Zinc

Copper—The outstanding feature of the last week was the continued pressure to sell Lake copper which was offered on even terms with electrolytic. The domestic demand was light. The relatively small business reported was done at 17.82½@17.87½c., regular terms, delivered in Connecticut. Some half-million and million-pound lots were sold on that basis, the deliveries being for November and December. Copper for any delivery was available in large quantity at the same price.

There was a good demand for copper from Europe and excellent prices could be realized by anybody who could find the freight room. The deficiency of the latter continued to be an obstacle to this business.

The domestic consumption of copper appears to be improving, this being indicated by the inquiries from concerns that have nothing to do with the ammunition business.

Copper Sheets are quoted about 23c. per lb. for hot rolled and 24c. for cold rolled, with usual extras. Wire prices are unsettled; quotations may be put at 19½@19¾c. per lb. at mill. The chief maker does not quote base price.

Imports of Copper for the week ended Sept. 25 as reported by the Department of Commerce were 3,706,464 lb. metal and 3,089,314 lb. in ore and matte; 6,795,778 lb. in all. The chief imports were from Peru, Cuba, Canada and Chile. Exports for the week were 8,273,826 lb., the chief items being 5,257,786 lb. to France, 1,368,899 lb. to England and 1,273,266 lb. to Italy.

Visible Stocks of Copper in Europe on Sept. 30 are reported as follows: Great Britain, 20,995; France, 4,163; afloat from Chile, 825; afloat from Australia, 3,000; total, 28,983 long tons, or 64,921,920 lb. This is a decrease of 3,169 tons from the Sept. 15 report.

Tin—This market was dull and quiet, the price sagging off when the excitement over the prospective British export duty waned. The New York Metal Exchange on Oct. 8 passed a resolution to the effect that its existing form of contract was clear upon the point that any such duty that might be levied must be paid by the buyer. Nothing more definite respecting the imposition of such a duty appears yet to be known.

Tin production of the Federated Malay States eight months ended Aug. 31 was 33,075 long tons in 1914, and 30,908 tons in 1915; decrease, 2,167 tons.

Visible Stocks of Tin on Sept. 30 were: Great Britain, 5,120; Holland, 5; United States, excluding Pacific ports, 10,066; total, 15,191 long tons, an increase of 64 tons during September. The figures include 6,968 tons afloat.

Shipments of tinplates from the United States to Great Britain are unusual. Shipments from Baltimore for the past week, however, included 2,476,768 lb. tinplates to Glasgow.

Lead—This market stiffened upon the appearance of some fairly large orders from abroad which developed into business. The quotations at St. Louis improved a little, but in New York business was done at the old price, at which supplies of lead appeared to be freely available.

Spelter—This market dropped right through the week, there being no general demand worth mentioning from domestic consumers. On the other hand, the big demand from Europe continued and many thousands of tons were sold for export far ahead, most of the principal producers participating in this business. These contracts were made generally to run through long periods beginning in October or November, and running to March or April. The stock of spelter available for immediate delivery appears to be increasing, but smelters are naturally more interested in selling their prompt supplies in conjunction with distant futures than they are in selling for early months alone. The demand for early spelter is, however, so light, that producers who are willing to sell in that way have been obliged to offer the metal down and toward the close of the week prompt spelter was liberally offered at 13c., with the probability that any firm bids of 12¾c. would be snapped up. As has been noted above, the bulk of the transactions were for export, on long-running terms. One large domestic contract, on such terms, was reported, but this appeared to be an isolated transaction, the domestic interest having by no means been general. The galvanizers continued to be conspicuous by their absence.

Zinc Sheets—Business has been active, sales good but with no material change in quotations. The base price for carload lots is $16 per 100 lb. f.o.b. Peru, Ill., less 8% discount.

In this table of prices the figure for sterling exchange of Sept. 22 was given at 4.470, through a typographical error. The correct figure was 4.700 for that date.

DAILY PRICES OF METALS IN NEW YORK

			Copper	Tin	Lead		Zinc
Oct	Sterling Exchange	Silver, Cts. per Oz.	Electrolytic Cts. per Lb.	Spot, Cts. per Lb.	New York, Cts. per Lb.	St. Louis, Cts. per Lb.	St. Louis, Cts. per Lb.

13	4 6725	49½	@ 17 67½	32½	4 50	@ 4 45	@ 13 00

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies, and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St. Louis is given as the basing point. St. Louis and New York are normally quoted 0.17c. apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars. Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash. The difference between the price delivered and the New York cash equivalent is at present about 0.20c. on domestic business. The price of electrolytic cathodes is 0.05 to 0.10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands. Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St. Louis being the basing market. We quote the New York price at 17c. per 100 lb. above the St. Louis price.

Silver quotations are in cents per troy ounce of fine silver.

Some current freight rates on metals per 100 lb. are: St. Louis-New York 17c.; St. Louis-Chicago, 6.3c.; St. Louis-Pittsburgh, 13.1c.

Other Metals

Aluminum—The scarcity of metal for early delivery is still the main feature in the market. For such deliveries prices are firmer and as high as 55@57c. per lb. has been paid for No. 1 ingots. For futures no quotations are available.

Antimony—Business has been rather more active, with some fair-sized transactions. Prices remain about the same, 28@29c. per lb. for Chinese and other ordinary brands; 45@46c. per lb. for Cookson's. A large shipment of Chinese metal is held up by the trouble in the Panama Canal.

Nickel—Quotations for ordinary forms are nominally 45@50c. per lb., according to size and terms of order. A premium of 3c. per lb. is charged for electrolytic nickel.

Quicksilver—The market has been active and is strong, on account of the scarcity of stocks, which are very low. In New York quotations are $92@94 per flask of 75 lb. for both large and small orders. San Francisco reports by telegraph quotations $87.50@92 per flask, with brisk demand and stocks low. London price is lower, £15 10s. per flask, with no discount from second hands.

Gold, Silver and Platinum

NEW YORK—Oct. 13

Gold receipts of $6,000,000 from Australia at San Francisco are reported this week.

Platinum—The market continues uncertain and no new supplies have been received. Prices remain high, and we quote $51@55 per oz. for refined platinum, and $55@59 per oz. for hard metal.

Our Russian correspondent writes under date of Sept. 8 that the market has shown an extraordinary increase in activity and prices. This has been mainly due to the scarcity of foreign bills and the high rates of exchange. In Petrograd these rates have stood as high as 14 rubles to £1 and 3 rubles to $1—the normal rates being 9.40 and 1.94 rubles. Speculators have bought large quantities of platinum for export to secure the bills, which can be sold on the Stock Exchange at a high profit. The advance has been as much as 6,000 rubles per pood. The current quotations for crude metal, 83% platinum, are 10@10.50 rubles per zolotnik at Ekaterinburg; 38,000@40,000 rubles per pood at Petrograd; equal to $38.54 and $38.22 per oz., average.

Silver—The market continues steady with slightly upward trend, but the decline in sterling exchange has reduced the New York price from 49¾c. on Oct. 7 to 49½c. on Oct. 13.

Zinc and Lead Ore Markets

PLATTEVILLE, WIS.—Oct. 9

The base price paid this week for zinc ore was $76@80 per ton for 60% grades; medium grades sold at a base price of $72@75 per ton. The base price paid for 80% lead ore was $53@55 per ton. The shipment this week was the largest on record for the Wisconsin District. The net tonnage of zinc ore for the first nine months of 1915 exceeded the figures for the corresponding period of last year by 31,539,810 lb.

SHIPMENTS, WEEK ENDED OCT. 9

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	4,643,370	214,500	620,580
Year	152,849,410	4,996,120	21,114,770

Shipped during week to separating plants, 7,123,460 lb. zinc ore.

JOPLIN, MO.—Oct. 9

Blende, high price, $89.50, base per ton of 60% zinc, premium ore, $87.50; medium grades, $87@85; lower, $84@80; calamine base per ton, 40% zinc, carlots, $60; average, all grades of zinc, $81.99 per ton. Lead, high price, $56; base per ton 80% metal content, $55@50; average, all grades of lead, $50.53 per ton.

	Blende	Calamine	Lead	Values
Total this year	414,689,820	33,707,780	69,506,010	$19,560,050
Total this week	11,684,410	62,000	1,784,130	$526,640

Blende value, the week, $479,700; 41 weeks, $16,968,210.

Calamine value, the week, $1,860; 41 weeks, $768,920.

Lead value, the week, $45,080; 41 weeks, $1,822,920.

An entire week with very light rainfall encourages a belief that the excess is past and lends promise of a possible moderation for some time. Water is very heavy in the mines and the strain on pumping machinery causes frequent trouble, it is generally under control in all the large mines, but some small mines are still idle. The lighter shipment of this week added approximately 600 tons stock in the bins. Buying was lighter to the close, with a feeling among buyers of an easier market next week.

MONTANA ZINC ORE

In September the Butte & Superior mills treated 40,400 tons ore saving 11,600 tons concentrates, containing a little over 13,000,000 lb. zinc.

Iron Trade Review

NEW YORK—Oct. 13

Export orders continue large and domestic business is growing steadily. Structural work is the slowest end of the market, but is improving.

Orders for rails are coming in quite freely, and many companies are making up their orders for next year. More orders for cars are also noted.

Steel companies are rather holding back on orders for 1916 business, at any rate beyond the first quarter. Most of the mills are so full that they are not able to guarantee early deliveries. Price advances are being firmly held and some more are expected to be made before long.

Pig iron is in greater demand and quotations are firm, notwithstanding the increased production. It is to be noted that a good share of the larger make in September was from the steel works furnaces. There has been no considerable buying for next year thus far, and not much is expected this month.

The United States Steel Corporation reports unfilled orders on its books on Sept. 30 at 5,317,618 tons of material of all kinds. This is an increase of 409,163 tons over the statement for Aug. 31, and is the highest figure reported for many months.

Pig-Iron Production again increased in September. The reports of the furnaces, as collected and published by the "Iron Age," show that on Oct. 1 there were 268 coke and anthracite stacks in blast having a total daily capacity of 97,535 tons of iron; an increase of 6,460 tons over Sept. 1. Making allowance for the charcoal furnaces, the estimated production of pig iron in the United States in September was 2,882,500 long tons; for the nine months ended Sept. 30, it was 20,518,500 tons. Of this total 15,072,575 tons, or 73.5%, were made by furnaces owned and operated by the steel companies. Production in September was at the rate of about 35,000,000 tons a year.

PITTSBURGH—Oct. 12

Week by week the steel mills find themselves more oversold, with respect to deliveries they should be making currently, and with respect to specifications booked for forward shipment. In bars, plates and shapes specifications on open contracts are coming in so freely that Jan. 1 will probably find the large mills with specifications on books for three months of solid work. That will not mean that buyers will necessarily be inconvenienced through delay in delivery, as much of the tonnage now being specified is being placed because buyers realize the delivery will be slow. The condition greatly strengthens the market as the mills have little occasion to sell for first quarter, and prices are going up. With such slow deliveries the small mills, which do not sell ahead, are reaping a harvest on prompt business, at premium prices, as high as 1.60c being paid for plates for early delivery. On bars, plates and shapes the large mills are generally quoting 1.40c. on specific orders for delivery at mill convenience, and 1.45c. on first-quarter contracts, in case they quote at all.

Sheets are stiffened rapidly, with 2.00c. as minimum on 28-gage black, for bessemer, and 2.05@2.10c. for openhearth, with no selling for first quarter, except specialties and at advanced prices. The wire mills have very little to offer in plain wire and in barb wire they are filled solidly for at least three months.

Railroads have already contracted for at least 400,000 tons of rails for next year, and they are eagerly buying plain steel and track material both for early and for extended delivery.

The scarcity of steel is due in large part to the war demand, which diverts much steel to forging shops and also curtails the supply available for finishing mills by the specifications requiring heavy cropping from the ingots, 30% very commonly.

It is now quite generally predicted that steel prices will advance more sharply in the next three months than they have in the past three, owing to the physical conditions as to demand and supply, coupled with the new idea among steel mills that little if anything is to be gained at this juncture by endeavoring to keep prices within bounds, when higher and higher prices are evidently to be obtained without difficulty.

Pig Iron—The market continues very quiet. Some of the merchant stacks that recently went into blast are but indifferently supplied with orders, even for early deliveries, and buyers show no anxiety about the future. Evidently they are convinced that whatever shortage there may be of steel there will be ample supplies of pig iron. With recent advances the less well positioned furnaces should be able to make profits, and there remain a fair number of merchant stacks idle. While Lake Superior ore is expected to be about 50c. higher for next season, and Connellsville coke has advanced somewhat, all the advances accomplished or in prospect in blast-furnace raw materials are covered by advances that have already occurred in pig iron. The foundries as a class are not really busy. If their condition should change materially for the better advances in pig iron might easily be resumed. We quote: Bessemer, $16; basic, $15; malleable, $14.50@15, according to analysis; No. 2 foundry, $14.50@15, according to delivery, all f.o.b. Valley furnaces, 95c. higher delivered Pittsburgh.

Ferromanganese—The market continues rather uneventful, with foreign on contract quoted at $100, Baltimore, for indefinite delivery and domestic at $115, for assured delivery, prompt lots commanding intermediate prices.

Steel—The demand for special steel for forging shells and for rolling large rounds for shrapnel has taken up all available openhearth capacity, with an insistent demand left. Mills are securing $140@45 for billets for rolling shrapnel rounds, under special specifications that are not difficult and make very profitable business, to the entire neglect of ordinary soft-steel openhearth billets. There are occasional offerings of openhearth sheet bars, at $27@27.50, Pittsburgh. Consumers are likely to turn more to bessemer, which has lately been neglected. It is understood that occasional lots of bessemer might be obtained at $25@25.50. Youngstown, for billets and $25.50@26 for sheet bars. Rods are nominal at $31, Pittsburgh.

FERRO-ALLOYS

Ferromanganese is quoted at $110@$115 per ton for domestic 80% material. **Spiegeleisen** has been sold at $27 per ton for 20%, at furnace.—**Ferrosilicon**, 50%, is quoted at $75 per ton at Pittsburgh. Bessemer ferrosilicon is from $20 per ton for 10% up to $24 for 14%, all at furnace.—**Ferrotitanium** is $@12½c. per lb., according to size of lots and delivery.—**Ferrovanadium** is $2@2.25 per lb. of contained vanadium.—**Ferrotungsten** is quoted in London at 7s.@7s. 6d. per lb.—$1.68@1.80—for alloy 75@80% tungsten.—**Ferro-molybdenum** is quoted in London at 18s.—$4.32—per lb. for 75% alloy.

IRON ORE

Shipments of iron ore from the Lake Superior regions in September were 7,863,146 long tons, the heaviest September shipments on record. For the season to Oct. 1 the total shipments were, in long tons:

Port.	1914	1915	Changes
Escanaba	3,019,651	4,011,682	I. 992,031
Marquette	1,385,718	2,313,532	I. 927,815
Ashland	2,741,917	3,829,582	I. 1,087,665
Superior	9,478,253	5,937,023	D. 3,481,230
Duluth	5,278,800	11,807,219	I. 6,528,320
Two Harbors	4,804,975	6,710,528	I. 1,905,553
Total	26,709,413	34,669,566	I. 7,960,153

Shipments from Superior decreased on account of the light work this year on the Hill ore lands.

Some additional sales of Lake ore for this season's delivery are reported, a furnace company in the Mahoning Valley having taken 100,000 tons. October shipments are being rushed. A severe storm on the Lakes delayed shipping last week.

The total iron ore mined in New Jersey in 1914 is reported by the State Geological Survey at 350,135 long tons. The quantity sold was 346,820 tons.

OTHER ORES

All production of molybdenite, of wolfram ore and of scheelite in Australia has been requisitioned by the Commonwealth. The prices fixed for molybdenite are 105s.—$25.20—per unit for molybdenite and 55s.—$13.20—per unit for wolfram or tungsten ore. Australia supplies a considerable part of the demand for these ores. Burma is also a considerable producer.

Molybdenite. 90% MoS_2 is quoted in London at 120s.—$28.80—per unit.—**Tungsten** ore is high. wolfram, 65% WO_3 being quoted at 55s.—$13.20—per unit.

COKE

Coke production for the week in the Connellsville region is reported by the "Courier" at 397,589 tons. Shipments, 395,243 short tons. Production of Greensburg and Upper Connellsville districts, 44,715 tons. The "Courier" states the Connellsville production for the third quarter at 4,063,811 short tons, for the nine months ended Sept. 30, at 12,300,358 tons.

Anthracite shipments in September are reported at 5,535,771 long tons. For the nine months ended Sept. 30 the total shipments were 50,067,589 tons in 1914, and 47,379,111 tons in 1915; a decrease of 2,688,470 tons, or 5.8%, this year.

Connellsville—Contracting for furnace coke for 1916 delivery is proceeding at a moderate pace, and at prices a shade lower than operators expected a month ago they would be able to obtain. Contracts closed thus far on the movement amount to between 125,000 and 150,000 tons a month, somewhat more than half being for the full year rather than the half year, buyers being tempted by the fact that operators will sell at as low a price for the year as for the half year, and sometimes at a shade lower. One contract recently made at $2.35 for six months has been revised, at the request of the buyer, at $2.25 for the entire year, the operator being well satisfied to make the change, and these prices represent the markte quite closely. Operators are more inclined to sell at such flat prices than on the sliding-scale basis, which generally gives $2.25 coke on $15.50 pig iron, $2.35 on $16 pig iron and so on, when the market basis now is only $15, making a settling basis for coke at $2.15. Spot furnace coke has stiffened fully 5c. and is now quotable at $1.85@1.90. Foundry is quotable $2.30@2.60 for prompt and $2.40@2.60 on contract.

Fuel Exports of Great Britain eight months ended Aug. 31, in long tons:

	1914	1915	Changes
Coal	44,257,161	29,522,179	D 14,734,982
Coke	694,061	576,218	D 117,843
Briquettes	1,324,937	864,503	D. 460,434
Steamer coal	13,249,027	9,657,927	D 3,591,100
Total	59,525,186	40,620,827	D 18,904,359

Steamer coal is that furnished to steamships in foreign trade. The heavy decrease shown this year is due to the war conditions.

Chemicals

NEW YORK—Oct. 13

The general markets show little change, but there is a slight gain in business in several lines.

Arsenic—The market is quiet and rather dull. Prices are unchanged. Quotations are $3.50 per 100 lb. for large lots, and up to $4 for smaller orders.

Copper Sulphate—Business is steady and no change can be reported. Quotations are $6.75 per 100 lb. for carload lots and $7 per 100 lb. for smaller orders.

Nitrate of Soda—The market for this article continues strong and business has been on a fair scale. Prices are firm and 2.45c. per lb. is bid for both spot and futures.

Production in Chile is improving and is expected to increase still further. That for August was 4,961,580 quintals, or 23,125 tons.

Pyrites—Arrivals at Baltimore for the week included 5,822 tons of pyrites from Huelva, Spain.

Imports and Exports of Fertilizing Chemicals in the United States, seven months ended July 31, in long tons:

	Imports		Exports	
	1914	1915	1914	1915
Kainit	291,875	6,646	.	.
Manure salts	135,422	12,647	.	.
Other potash salts	170,091	66,821	2,228	600
Nitrate of soda	341,480	436,944	5,862	12,771
Sulphate of ammonia	45,383	23,519	.	1,186
Phosphates	.....	.....	878,147	111,703

Exports include reëxports of foreign material. Some phosphates are imported, but are not reported separately in the returns.

Imports and Exports of Raw Material for Chemical Manufacture, seven months ended July 31, in long tons:

	Imports		Exports	
	1914	1915	1914	1915
Sulphur	9,432	13,121	81,2	7
Pyrites	577,489	450,321		
Chrome ore	42,071	18,555		
Magnesite	82,741	16,911	1	0

Exports include reëxports of foreign material. The sulphur sulphur contents of pyrites the total imports of sulphur this year were 193,341 tons.

PETROLEUM

Exports of mineral oils from the United States in August were 232,224,014 gal. For the eight months ending with July 31 the total exports were 1,443,937,331 gal. in 1914 and 1,718,884,770 gal. in 1915; an increase of 24,947,439 gal. this year.

Moving Ore in Flat Stopes

By E. M. Weston*

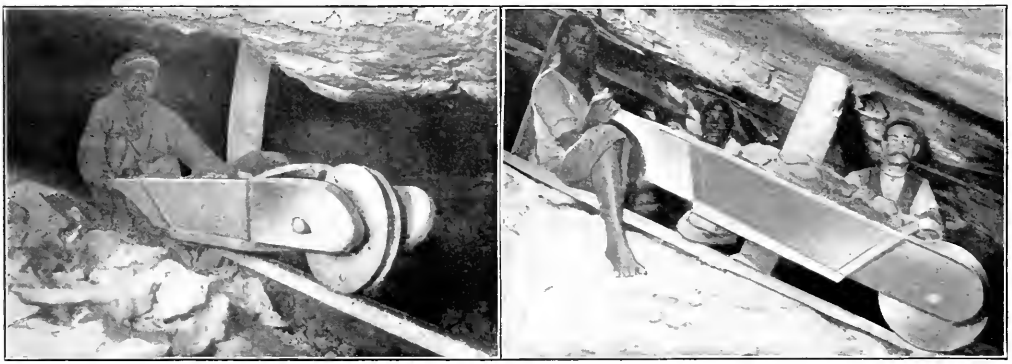
SYNOPSIS—Methods devised on the Rand for moving ore in flat stopes. Shallow wheelbarrows with grooved wheels running on a monorail prove efficient. Sharp curves and grades changing quickly from flat to 25° are no obstacle, but slightly smaller barrows are used. Is better method for Rand conditions than shaking chutes, is far cheaper than shoveling, and suits habits of native laborers admirably.

A serious problem has always existed in working small ore or coal deposits having a dip of from 5 to 20°, where the deposit is irregular, or where the timbering necessary is such that rails cannot be laid into the face; also where shaking conveyors are either too expensive to install or the dip too flat to render them effective.

The problem has been to avoid the amount of hand shoveling necessary to bring the ore either to the nearest tram line or to some central installation of "shakers" or other conveyors. Recent articles in the *Journal* dealing with such cases have described the use of small trucks running on rollers, as in the North Star mine, California, or an arrangement of a fixed iron chute to facilitate shoveling.

The question in some parts of the Witwatersrand is a most important one. Shoveling a "lashing," as it is called, is generally most inefficiently done. The native, unless well-taught, prefers to use his shovel like a hoe and to scrape the ore along instead of lifting and throwing it. There is often far too much of lashing down 100 or 200 ft. of stope on the Rand. I was given charge of reclamation work in an area of a mine consisting principally of stopes of the grades mentioned, where comparatively small quantities of rich ore in pillars and overlooked foot- and hanging-wall sections were spread over considerable distances from tram lines and where the stopes were often narrow. Ore had sometimes to be brought through places not more than 30 in. high.

I was compelled to consider some method of avoiding the excessive amount of shoveling that would have rendered much of the ore too costly to remove. I finally decided that the solution of the problem lay in adapting the old Cornish barrow to new conditions. The plan was to use a combination of a monorail truck, a Cornish barrow and a sled. The construction of a wooden model is shown in the photographs.



NEW SYSTEM OF CONVEYING ORE FROM FLAT STOPES OF THE RAND

The 2-cu.ft. wooden stope barrows shown above were used in the lower stopes and a 3-cu.ft. steel barrow in higher stopes

When the barrow had to be taken around curves and when there were changes of grade from flat to 25°, I found that a barrow having a capacity of 2 cu.ft. was the most economical size to use. Where there was a regular slope not exceeding 18° and where straight lengths of rail could be used, a 3-cu.ft. steel-plate barrow, such as is shown in the drawing (p. 666), could be easily handled. However, the right capacity may easily be found by experiment.

From the illustrations the construction and method of use of these barrows are easily seen. The wooden barrow is made of 1-in. or 1¼-in. boards, held together with strap iron along the back of the [illegible]. There is

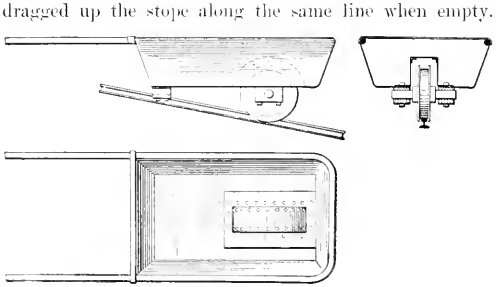
*Mining engineer, Union Club of South Africa, Johannesburg, Transvaal, Union of South Africa.

at the back a removable wearing piece of harder wood about 4x2½ in., with a slight groove cut in the center for the top of the rail to slide in. This is gradually cut through by the friction and is renewed underground as required.

The barrow as a whole suffers little wear from rock shoveled into it, and I had not renewed a single bottom during the course of a year in consequence of this wear. The wheel is made from a circular piece of hardwood board about ½ in. thicker than the rail upon which it has to run. On each side of it is bolted a circular disk of ⅛-in. steel plate, having a diameter about ¾ in. longer than that of the wooden disk. These form flanges that keep the wheel upon the rail. The disks are cut out to receive a wooden hub 1 in. square, turned down on each side to a 2-in. pin. In the latest design, this pin or axle works in blind bearings cut in blocks of wood, screwed or bolted to the inner sides of the side pieces of the barrow, so that the wheel can easily be changed by unscrewing. The flanges are strong enough so that the barrow can be wheeled along a plank or along the bottom rock of a stope when necessary.

In taking a load of ore down a narrow stope, the barrow is pushed forward and slides along on the wheel and on the back wearing piece, while the operator holds the handles and thus prevents a capsize. In a difficult or flat place, the method of progression is by a succession of pushes, but in easy places it is really a gentle advance on the slide with the operator, half crouching, following it.

It suits the habits of the natives admirably, and they soon take to the use of it when shown. It is of course dragged up the stope along the same line when empty.



WHEELBARROW FOR USE IN FLAT STOPES

In rounding curves, the native soon learns to swing the rear of the barrow so that the wheel does not jam.

The great advantage of this system is the simplicity and speed of track laying. The track consists of a single length of old or new rail, which can quickly be bent to avoid timbers or packs in a stope. The rail is supported upright in the simplest manner with old pieces of timber larger than 6 in., secured by nails or spikes, or by old iron sleepers cut in half and attached so that they project on opposite sides of the rail. With a few pieces of timber, some nails and perhaps some coupling plates and bolts, any unskilled man can lay a line without trouble in a few minutes and take it up again if necessary to preserve it from the blast at the end of the shift.

This is not the only advantage—a main line, single or double, can be laid into a face, and from it branch lines can be laid off to various parts of the stope. The junctions of the rails are simply the ends or sides laid together; the operator of the barrow simply lifts its front wheel from one rail to the other and continues on his way. Several barrows can run on the same line in opposite directions, as the empty barrow is simply tipped off the rail when meeting occurs and put on again in a short time.

The saving in capital expenditure is obvious. The barrows cost only 30s. or less and last a long time. They are easily moved away from the area of blasting, and any repairs can be cheaply made. The various items of the equipment are found in any mine and may be used over again many times.

The next question to be answered is—what is the efficiency over other forms of conveyors and over shoveling? I have already stated that such a method makes no claims of superiority to regular stope tracks or regular conveyors in handling large tonnages. It may be useful in feeding them. Its place is apparent when the regular methods are not suitable. For moving broken rock it is more efficient than shoveling, if the distance the rock has to be moved is more than about 30 ft., but in the case of the barrow there must be a place where the rock can be tipped with ease or it must be removed as soon as tipped. This means that the rock cannot be efficiently piled up in a heap with a barrow.

In the flatter stope shown in the photographs, one native without close supervision loaded and moved three tons (30 barrows) every shift over a distance of 300 ft. Another moved five tons in a higher stope. With larger barrows two natives loaded and moved enough rock down 100 ft. of line in a 15° stope to keep two other natives employed shoveling it into a 14-cu.ft. truck, tramming it 200 ft. and tipping it. These two natives with barrows did the work of six or eight natives by the old shoveling method. The native must be taught how to use the barrow, but he soon takes to it as the change of work appeals to him. It is easier with this method than with shoveling to get definite results from a given gang of natives under a boss boy, as each native has a definite task to do and need wait on no one. A tally of the barrows moved can be kept and a contract system arranged.

Several engineers who saw the system at work endeavored to introduce it in other mines, but it is quite impossible to introduce any new system on the Rand, however good it be, without first starting on a small scale and gradually training men and natives in its use. Otherwise it is at once voted a nuisance and the first opportunity is taken of leaving the apparatus in the stope to be blasted. This is a true picture of Rand conditions as many can testify from bitter experience.

Nature of Title to Mine Claims

By A. L. H. Street*

A comprehensive statement concerning the nature of mining claims and the method of their acquisition, made by the United States Circuit Court of Appeals, Ninth Circuit, in the late case of Trinity Gold Dredging and Hydraulic Co. vs. Beaudry (233 Federal Reporter, 739) appears in the following concise paragraph:

Congress has provided how a mining claim can be acquired. In general, it may be acquired by discovery of mineral, par-

*Attorney, Security Building, Minneapolis, Minn.

ticularly of gold, silver or copper and the like, upon the public lands and by staking the same off or marking it upon the ground so that the boundaries may be plainly designated and readily ascertained. The right of continuous occupation may be maintained by keeping up the assessment work prescribed by law, and this without incurring the obligation toward the Government of buying and paying for the land. When an individual entitled to the benefit of the statute has made location in accordance therewith and gone into possession, he is said to be the owner and in possession of the mining claim thus located. Such a claim, when perfected, is declared to be property in the highest sense of that term, which may be bought, sold and conveyed and will pass by descent. . . . It has been held, further, that the words "mining ground," used in a deed, have a technical meaning and refer to that interest which a mere occupant of the mine has in the same; and that a purchaser of a mining claim only acquires such right or title from his vendor as the latter had at the time of the purchase. . . . A mining claim is therefore possessory only in character, where held by location simply and the performance of the annual work necessary to entitle the locator to continue in possession.

*

Drift Mines of California

By John D. Hubbard*

The lava-capped sluice boxes of nature, known as the Tertiary or ancient river channels of California, have had a remarkable history of gold production, and it seems surprising that more attention has not lately been given to them. The result of a vast period of erosion, these ancient channels have proved their superiority over the later Quaternary channels in point of actual gold production. In fact the Quaternary channels derived by far the larger part of their gold from the sluicing or erosion of the others. The record of the Tertiary channels, approximately 300 mi. of which were worked, is a production of $300,000,000 in gold, or $1,000,000 per mile of channel worked. The remainder of California's vast gold production—approximately $1,650,000,000—came from the quartz veins and the Quaternary "diggings" of the Argonauts.

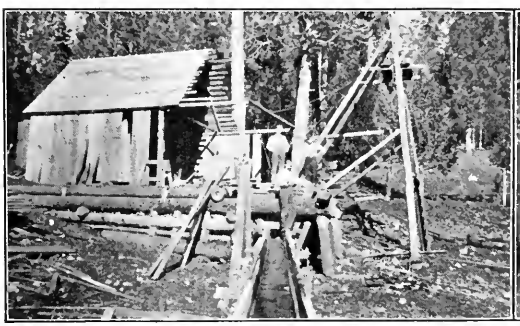
An idea seems to prevail that California has been pretty well worked over and that not much is left. This is not true. Of the Tertiary channels alone there remains over 1,000 mi. of unworked main channel, to say nothing of the tributaries. There is every reason to believe that the averages of production will continue to hold good, this source alone supplying more than $1,000,000,000. Besides, the quartz veins are to be reckoned with, and will continue to pour their riches into the world for many years.

*Mining engineer, San Francisco, Calif.

The heyday of hydraulic and drift operations in the Tertiary gravels passed away in the '70s of the last century. Since then, owing to the anti-débris laws, hydraulic mining has practically ceased in the watersheds of the navigable rivers of California, although still carried on in the non-navigable river districts, as the Klamath. Although the anti-débris laws do not apply to drift mining, a stagnation in this industry followed the closing down of the hydraulic mines. The main problems in the drift mines are to extract the gravels without damaging other property with the débris and to reduce the cost of drift mining so as to permit the exploitation of the less remunerative deep gravels, such as lie along the ancient shore line of the Neocene-Cretaceous contact.

Most of the Tertiary channels lie in a favorable position for gravity working, especially in the lower reaches of the Sierras. Where the old river bed may be tapped by a lower tunnel and the gravel mined out on a gravity system the costs are greatly reduced. The débris from these mines may also be retained in a small area by the proper disposal of the water used in washing through the sluice boxes. The débris or gravel being heavy has a tendency to "stay put" with but little encouragement.

The cost of drift mining varies greatly, depending on conditions. At the Mayflower mine in Placer County, according to F. Chappellet, the mining cost is $1.19 per ton, and milling with steam power, 25c. per ton, or a total of $1.44 per ton. This was in cemented gravel. At the Big Dipper mine, which is of the same class as the Mayflower, the total cost, according to G. B. Hobson, was $1.85 per ton. At the Hidden Treasure mine, where the gravel is not milled and the work is done on a large scale, the cost per ton is as low as 92c. At the Mineral Slide mine, near Magalia, in Butte County, where the face is blasted down and the gravel washed out by water under pressure, the cost is as low as 65c. per ton. This is about the lowest figure recorded, but even that can be lowered. At the Nugget mine in Butte County, where the gravel was worked through an incline and water had to be pumped, the cost was $1.37 per ton, increasing to $1.73 per ton as greater depth was obtained. It would be a great benefit to the mining fraternity if the costs of such extensively worked drift mines as the Magalia and Indian Springs in Butte County were available, but the owners took the gold out so fast that they could not be bothered with costs.



HEAD OF INCLINE ON DRIFT MINE STARTING WORK, BUTTE COUNTY, CALIF.

NUGGET MINE, BUTTE COUNTY, CALIF., SHOWING SLUICE AND UNDERCURRENTS

Because of the prevailing harder bedrock and greater fall of the ancient river, the gravel in the California mines, in contrast to many Australian drift mines, rarely contains much clay. Consequently the Australian methods of puddling or comminuting the clay by revolving drags in pans are practically unknown in California. There are many localities in California where plenty of clay has been found in the Quaternary gravels, but the ancient channels of the Tertiary are remarkably free from this objectionable material.

Like everything else, drift mining must be attacked with skill and "horse sense." It is an attractive game. Once touched by the sight of beautiful shining yellow gold under clear water in the sluices and by the sensation of handling it before it becomes "tainted," a man is apt to forget quartz mining and the methods which call for expensive reduction plants. Getting the pure article at first hand is so much more satisfactory.

One phase of the situation as regards future exploitation is the unsatisfactory and wholly erroneous way of placing the value or selling price on a gold mine. To the miner gold stands for copious perspiration. To the business man it is something else. But gold and perspiration are rarely associated in the mind of the landowner when there is a prospective buyer. Without a considerable showing in development work it is impossible to place a price with any reason on a mine. Owners can seldom tell you anything about reserves, but never slip a heart-beat in naming a price. This means to the operator that in case of acceptance he is betting his time, skill and development money against nothing that the price asked is right. No wonder the industry has languished.

But things have changed. Owners now court activity on any reasonable terms. They have eaten crow long enough. Many are disposed to meet the operator half way, and to do it on a percentage basis. By this method both sides take their risk like good sports, which is good business in the end.

New Flotation Installations

SPECIAL CORRESPONDENCE

A new flotation installation in successful operation at the Mary Murphy mine, near St. Elmo, Colo., consists of a 12-cell non-acid machine treating slimes from the wet crushing mill. The ore is a gold-silver-lead-zinc combination, and heretofore the values in slime have been difficult to recover. The flotation product from the 12-cell machine is re-treated on tables to separate the lead from the zinc, thereby making a higher-grade product than could formerly be secured with the system of wet milling and static concentration. The latter process is still handling the coarse material.

At the Oneida Stagg Mining and Milling Co., at Freeland, 5 mi. from Idaho Springs, Colo., there is an 8-cell machine of special design which has replaced the cyanide treatment. The cyanide plant contained four Dorr thickeners, three Dorr agitators, melting room, zinc boxes, filter press, air compressor and Dorr sand classifier. The present installation requires but one man per shift, the Dorr classifier and one thickener being used. The treatment is also non-acid. Feed to the machine is a gold-silver slime, carrying values in gray copper, chalcopyrite and pyrite. The flotation system recovers a high percentage of the feed, which is valued between $1.50 and $2 per ton.

An installation is being made now at Montezuma, Colo., of a non-acid system of flotation. The ore has been heretofore rather hard to treat on account of the heavy barite gangue, which is hard to separate by gravity from the mineral.

Cinnabar in Western Nevada

Two stray steers caused the discovery of a deposit of cinnabar in the Pilot Mountains of western Nevada, according to the United States Geological Survey. On the day of the discovery Thomas Pepper and Charles Keough had been tracking the two steers, when, near nightfall, the trail led over an old prospect in which a face of limestone traversed by small veinlets of red mineral was exposed. The red mineral was recognized by Keough as cinnabar. After finding the steers and taking them to Mina, the two discoverers returned to Cinnabar Mountain, as the hill on which they had made the find has since been named, where they spent 10 days in careful search and located 17 claims. They later went back to Mina and made known their find, causing intense excitement, and that afternoon almost every citizen of the town left for the site of the discovery by automobile and by other less expeditious conveyances. A large number of claims were staked by the first comers and many more were afterward staked by claimants from Tonopah.

The discovery was widely heralded as the rediscovery of the "lost Hawthorne quicksilver mine," named for Judge Hawthorne, in whose honor, it is said, Hawthorne, the seat of Mineral County, was named. According to local report, in the '70s Judge Hawthorne discovered a rich quicksilver deposit, which is believed to have been situated at the site of the recent discoveries. In returning from the mountains, so it is said, Hawthorne lost his bearings, and although to the end of his life he attempted annually to find the "quicksilver mine," he remained unsuccessful.

This tradition seems highly improbable. The original discoverer—who he was is unknown—had done some very substantial exploratory work on the prospect. In his efforts to prove his find he had blasted out a considerable mass of solid limestone, and as further tokens of his activity, sticks of powder, fuse and picks lay abandoned at the prospect. That this energetic prospector lost his way and was unable to find the prospect at which he had labored is not easily credible. It is more likely that he abandoned the prospect as, in his judgment, not sufficiently valuable. The newcomers have found considerably richer deposits than the unknown pioneer did and have shown that the cinnabar extends along a considerable belt.

Antimony in Hunan, China

United States Vice-Consul Horace Remillard at Hankow, China, reports that 11,156 tons of antimony, valued at $575,790, were exported from Hankow in 1914, a gain of 3,363 tons (11%) in quantity and $180,729 (46%) in value over 1913. Direct exports to the United States in 1914 amounted to 2,707 tons, valued at $319,966, a gain of 1,032 tons over 1913.

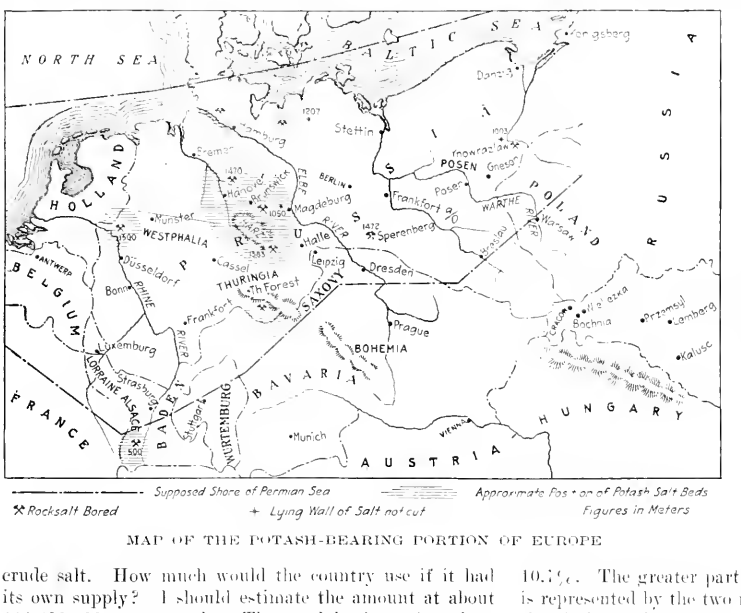
Potassium Salts: An Economic Geological Study—I

By E. Mackay Heriot*

SYNOPSIS—The great importance of the potash industry and the grip of the German monopoly upon the world's supply combine to make the subject of vital interest. The occurrence of the great deposits of potash is discussed, together with the probability of its discovery in other countries.

The potassium industry is of world-wide importance. I estimate that about 1,250,000 tons of pure potash (K_2O) are consumed in a year, or say a total of 12,000,000 tons of crude material with a value of $55,000,000. These figures, although they show great values and enormous tonnages, do not give any idea of what the world really needs. This sentence must be explained. Today Germany has a natural monopoly of potassium salts and is the only country which can produce them in great quantities. Germany uses over one-half of her potash output for domestic purposes.

Aside from Germany, the largest consumer of potash is the United States. It uses about 600,000 tons of the crude salt. How much would the country use if it had its own supply? I should estimate the amount at about 100,000,000 tons yearly. The exploitation of such a quantity should give employment to 370,000 men.



MAP OF THE POTASH-BEARING PORTION OF EUROPE

Uses and Derivation of Potassium Salts

Potassium salts have many more uses than as a fertilizer. There are few industries that do not need them in some form or other. Potassium arsenite is employed in the manufacture of cloth prints; potassium bromide, in photography, medicine and aniline dyes; potassium carbonate, for soap works, bleaching, dye works and glass; caustic potash, for bleaching, dyeing, soap-making and surgery; potassium chlorate, for fireworks, matches and dyes; potassium chloride, for freezing-mixtures and medicine; potassium chromate, for aniline dyes, electricity; potassium cyanide, for dyeing, making Berlin and Prussian blue, manufacturing cloth prints, hardening steel, galvanoplastic photography, and the extraction of gold; potassium iodide, for aniline colors, medicine and photography; manganate and permanganate of potassium, for dye works, coloring wood, disinfectants, bleaching works; potassium nitrate, for explosives, medicine and preservation of meats; potassium silicate, for painting, sticking-mixture, printing, water-glass, artificial stones, incombustible materials; potassium sulphate, for alum, glass, potash, caustic compounds. Thus potassium has become indispensable to trade and industry.

Potassium salts are derived from various crude materials, such as leucite, alunite, phonolite, greensand marls, kelp and dried salt lakes and underground deposits. Leucite is a metasilicate of aluminum and potassium, sometimes with small amounts of sodium when unaltered. Its formula is $KAl(SiO_3)_2$, and it contains 21.5% K_2O. It is found in igneous rocks, being chiefly developed in lavas of Tertiary and more recent ages, and but rarely in older rocks. It is met with in many parts of the world. As an example the rocks of the Leucite Hills, Sweetwater County, Wyo., consist of fine-grained, rather earthy-looking lavas, composed chiefly of a mixture of mica, diopside and leucite with a variable amount of orthoclase (potash feldspar). With the exception of diopside, all these minerals contain a considerable quantity of potash, the amount in leucite being about 21.5%; that in the orthoclase, 16.9%; and that in the mica, 10.7%. The greater part of the potash present, however, is represented by the two minerals, leucite and mica. The chemical samples show that the amount of potash (K_2O) varies in amount from 8 to 12%. It is calculated that these hills contain not less than 197,000,000 tons of potash;[1] but extraction is not yet commercially possible.

Alunite, $K(AlO_2H_2)_2(SO_4)_2$, is a hydrous sulphate of aluminum and potassium, with 11.4% K_2O. It is a secondary mineral in feldspathic rocks altered by means of sulphurous vapors. It occurs in altered rhyolites, dacites,

*Mining engineer, Rio Tinto, Huelva, Spain.

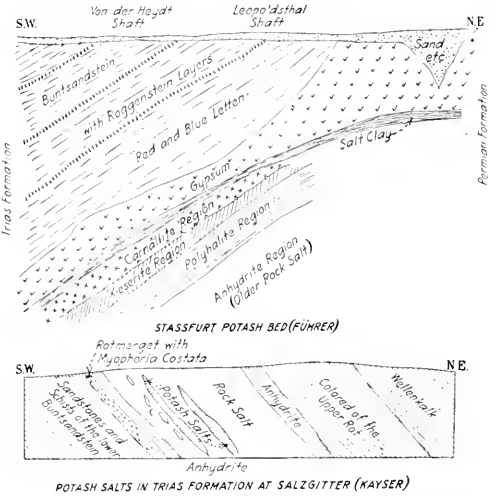
[1]Bull. 512, U. S. Geol. Surv., 1912.

trachytes and andesites. At Rosita Hills, Colo., it is found in andesite; with hyalite and opal at Queretaro, Mexico, and in many other localities.

Phonolite is a fine-grained volcanic stone containing from 9 to 10% potash. Germany, Iceland, Italy and other countries manufacture potassium salts from phonolite. One great advantage of this fertilizer is that it does not contain any chloride and should be suitable for potatoes, tobacco, grapes and fruit trees. There is said to be a very large supply in the Eifel, in Germany, where it is sold at $35.70 per car. Its merits seem to have been exaggerated.

The greensand marls of New Jersey are rich in glauconite formed by taking up potash from waters. The marl ranges from 3.5 to 6.3% potash. It cannot compete with concentrated fertilizers. Kelp is a source of potash. In Scotland, Norway and Japan potash and iodine are made from it.

According to "The Mineral Industry," vigorous work has been carried out in the United States, prospecting in the salt lakes for potash salts; but manufacturing seems



CHARACTER OF THE STASSFURT AND SALZGITTER BEDS

only to have been done on an experimental scale. American experts think that the most probable source of potash in America is Searles Lake, California. It is estimated that natural evaporation of the lake amounts to from 0.25 to 0.50 in. per day. Since the level is constant it follows that the lake is fed by an underground flow from the surrounding mountains and that the brine in the crystal body acts as an equalizer to the incoming water. The surface of the crystal body is predominately common salt. Below this are layers in which carbonate and sulphate of soda predominate and the potash seems mainly to lie on the border line. The crystal body is 70 ft. deep and the salt muds extend to at least 700 ft. The daily output of the complete plant is calculated as follows: Borax, 225 metric tons; soda ash, 508; salt, 1,507; sulphate of soda, 593; potassium chloride, 189. In other dried lakes prospecting is still going on in the Western states. In India crude soda has been obtained from the Loaur dried lake for centuries. Nitrate deposits in India, Chile and Africa furnish potash salts in relatively small amounts. From India and Chile about 30,000 tons of potash salts are exported annually.

I come now to the world's source of potash salts—the German deposits. They occur in the Permian formation. After discussing these I will then draw attention to potash deposits met with in non-Permian formation.

There are about 150 works now in the potash syndicate, and about as many more will be ready to produce in a few years.

In 1913 the total shipped was 5,212,651 tons.

	Tons
Carnallite and bergkieserite	68,217
Kainite and sylvinite	3,509,049
Potash manure salt, 20, 30 and 40%	906,212
Potash manure salt, to 80% KCl	37,873
Potassium chloride, 80%	484,254
Potassium sulphate, to 90%	110,784
Potassium-magnesium sulphate, to 48%	58,269
Potassium-magnesium sulphate, to 40%	119
Kieserite in blocks	36,708
Kieserite calcined and crushed	1,116

The principal product is potassium chloride, which serves as a basis for the manufacture of most of the other salts.

CONSUMPTION OF POTASSIUM CHLORIDE AND SULPHATE

	Potassium Chloride, Tons	Potassium Sulphate, Tons
Germany	130,889	2,865
England and Scotland	14,979	9,242
United States	230,214	41,818
Other countries	108,172	56,859
	484,254	110,784

CONSUMPTION OF KAINITE AND SYLVINITE IN 1913

	Tons
Germany	2,440,342
England and Scotland	74,352
United States	493,547

CONSUMPTION OF FERTILIZERS WITH MINIMUM 20, 30 AND 40%

	Tons
Germany	513,347
England and Scotland	15,307
United States	212,143
Holland	167,922

In the data I have given to show the output of the different classes of products I have mentioned some of the potassium minerals, and before going further will say something concerning these.

Carnallite, KCl, $MgCl_2$, 6 H_2O, is the mineral which forms the basis of the chemical industry. Chemically pure it contains 26.8 KCl or 14 K; 34.2% $MgCl_2$, 39% H_2O. In nature it is almost always associated with more or less rock salt, kieserite and other minerals through which the KCl is reduced by less than 50%. It is generally of a reddish color and easily soluble in water.

Sylvite, KCl, contains 52.48% K, and is usually of secondary origin, being derived from the decomposition of carnallite. In the Hanover region it is a primary mineral. When mixed with rock salt it is called sylvinite.

Kainite, KCl, $MgSO_4$, 3 H_2O, is formed by the decomposition of carnallite. It is usually mixed with a considerable amount of rock salt, and is called "hartsalt." This name is also applied to potassium-magnesium salts containing rock salt but no magnesium chloride. These require chemical treatment before they are commercially valuable. Schoenite (pieromerite), K_2SO_4, $MgSO_4$, 6 H_2O, is a secondary product of caruallite. Polyhalite, K_2SO_4, $MgSO_4$, 2 $CaSO_4$, 2 H_2O, occurs in the form of bands in the so-called polyhalite region. It has no commercial value. Kieserite, $MgSO_4$, H_2O, is the most important of the magnesia salts.

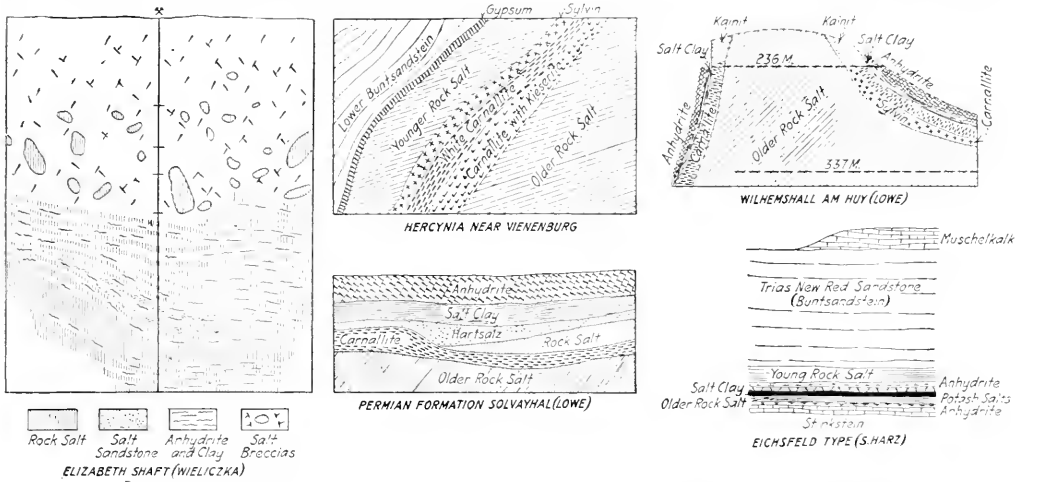
Other potassium salts found in the German deposits are glaserite, krugite, bischofite, tachydrite, astrakanite and douglasite. They have no commercial value. Boracite,

$Mg_7B_{16}O_{30}Cl_2$, occurs in the form of nodules in carnallite.

In order to get a good idea of the German potash deposits we must take ourselves back to the Permian era. I give a map of the world showing the relation of land to water at that time. It will be observed that what is now practically the whole of the Atlantic Ocean, including North America and Greenland, was a huge continent; the whole of Russia and Siberia was another; while Africa east and west to Australia and South America constituted a third—perhaps in this latter case not quite joined. Germany, it will be seen, was under a sea somewhat resembling the Mediterranean. This today is the so-called North German plain, under which are enormous deposits of salt. The map on page 669 shows the German Empire, and I have outlined as nearly as possible what is considered to have been the Permian Sea. On the east it enters Russia and on the west it most likely reaches England. At certain points I have marked with crossed hammers places where salt has been met with in deep borings. At the East Prussian frontier there is Ynowrazlaw, where at 1,003 m. the foot wall of the rock salt had not been pierced. In the south I show the celebrated borehole of Sperenberg, 1,472 m. deep and practically the whole way in salt. Up in the north near Hamburg lies the well-known salt mine of Jassenitz, the shaft of which took nearly 20 yr. to sink. A hole here had not got through the salt at 1,207 m. depth. To the west I show Munster, with a borehole 1,300 m. deep. Thus, it seems, we may say that without a doubt the North German plain is one vast salt area. However, it must not be thought that potassium salts are found everywhere. This is by no means the case. I have marked with horizontal lines the approximate situations of the potash fields.

In order to understand the geology of these salt deposits it is necessary to say something as to how they originated. There are two theories, but whichever one be right each gives a good insight into the geology and therefore should be mentioned.

Sea water contains 3½% of saline constituents, of which 2½% is sodium chloride. The remainder consists of magnesium compounds, calcium sulphate, potassium chloride, sodium bromide and small quantities boron, iodine and lithium salts. The open sea precipitates no salt, but in bays partially cut off from it there is precipitation. In a deposition of this class, gypsum forms the base and anhydrite the top of the salt deposit. Dr. Ochsenius, the great authority on the genesis of the German salt fields, says such a deposition is possible if we take a bay cut off from the sea by a bar so that only as much sea water runs over it as is compensated by evaporation from the surface of the lagoon, and the partially separated portion receives no large additions of fresh water. The sea water running in evaporates, and by the amount of salt it adds, the solid constituents are increased. Against this theory the question is asked why no fossils have been found in the salt formations. The answer Dr. Ochsenius gives is that such organisms, possessing free locomotion power, crossed the bar when the water became too salty for them. This to me does not seem a sufficient answer, as we shall see when describing other fields, such as Wieliczka, where many marine fossils are encountered. However, in the German salt mines not a single fossil has been found.



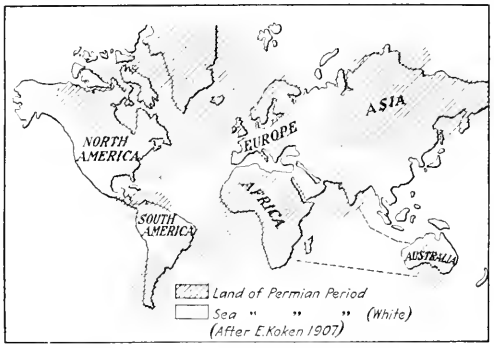
DIAGRAMS SHOWING THE CHARACTER OF THE GEOLOGY OF SOME POTASH DEPOSITS

Deposition of Saline Beds

First of all, gypsum is deposited forming the base. As soon as the saline solution has increased its weight content of salts eleven times, its specific gravity reaches 1.22 and the precipitation of sodium chloride begins. Dr. Ochsenius goes on to say that as the depositing process continues, the greater part of the deliquescent salts remains dissolved in the upper layers and constitutes the mother liquors which contain, along with sodium chloride, the potassium and magnesium compounds; that in the course of the continual growth of the rock-salt beds, and likewise of the mother liquors, the latter attain the level of the bar and commence flowing seaward as soon as their specific gravity can overcome the current of the inflowing sea water. After this stage is reached ordinary sea water can only have access through the upper portion of the bar mouth, the lower part being occupied by the outgoing mother liquors. At this point the last stage of the process begins; that is, the deposition of the uppermost bed of

calcium sulphate in the form of an anhydrite cap. After this the whole character of the bay changes. The dust caused by the disintegration of the neighboring rocks is blown onto it, causing the salt clay to be formed—a material generally to be found covering the potash salts. A case in point is the great bay of Adschi Darja, the narrow mouth of which is partially cut off from the Caspian Sea (Russia) by a bar. The bottom of the lake is covered by a thick salt layer. An analysis of the bed showed no potassium, but on the other hand the water contained 1% of potassium chloride, and in all 28.5% of salts.

Against the bar theory, which allowed of a periodical inflow of the ocean water without allowing the mother liquors to flow back over the bar, Walther says one would have to be able to find organic remains of such life as had flowed in with the water. Such would have been well preserved in the anhydrite or the salt. Out of the 150 mines at work not a single fossil has been found. To the paleontological difficulty of the bar theory must also be added a chemical one; if you evaporate salt water, at first a thin lime sediment is precipitated, then a sediment of gypsum and then rock salt. If, on the other hand, not sea water but another mixed solution of calcium sulphate and chloride is evaporated to dryness, anhydrite is precipitated



LAND AND SEA DIVISION OF PERMIAN PERIOD

and afterwards rock salt. The so-called "stinkstein" may represent the lime precipitated, but above this there is in reality no gypsum, but anhydrite from 50 to 100 m. in thickness.

From this it would seem that the North German Permian Sea was not in open communication with the ocean, but absolutely cut off from it and surrounded by a desert. Which theory be right is not of much importance in the present article: both give us a sound geological knowledge of these Permian salt deposits.

Such depositions are not necessarily limited to tropical places where there has been no rain. It is merely necessary that the evaporation should have been greater than the inflow of fresh water. The polyhalite rings show the changes of the year, and one may reckon that the older rock salt took about 10,000 years to deposit.

(To be concluded)

Dissociation Temperature of Ferric Oxide—C. S. Kinnison "Trans. Am. Ceram. Soc.," 1913, p. 136, states that ferric oxide at atmospheric pressure cannot exist above 1350° C., at which temperature and pressure it dissociates into oxygen and magnetic oxide. When fluxes are present the dissociation temperature is 1210 to 1220° C.

Coal Mining in Spitzbergen

A communication from United States Commercial Attaché Henry D. Baker, at Petrograd, gives some interesting particulars of the coal mining carried on in the island of Spitzbergen, articles on which appeared in the *Journal* of Mar. 20 and June 5, 1915. As the island is about 100 miles north of the northern coast of Norway and in about 80° north latitude, these operations constitute the farthest-north organized industry in the world.

The Coal Mines of the Island

Spitzbergen has a population of about 400 persons, mostly Norwegians, but including several Americans. Practically all the population is engaged in coal mining, the most important operations being conducted at Advent Bay by an American company, which has been working its claims for 10 years and now takes out about 50,000 tons per annum. All this coal, which is said to be of exceptionally high grade, is shipped to Tromsö, in northern Norway, and sold to the Norwegian Government for use on the State railways. There are also three Norwegian companies working claims in Spitzbergen—one at Advent Bay and two at Green Harbor.

To carry out the project of combining all the coal properties in operation under one company, there has been preliminary organization of a syndicate of Russian capitalists in Petrograd, which, at a cost of over $20,000, has already bought options for the right to purchase before Jan. 1, 1916, all the properties and claims in Spitzbergen, including that of the American company. A well-known mining expert engaged by this syndicate sailed in August from Tromsö for Spitzbergen, to spend several weeks in investigating all the claims and properties there. If his report corroborates the present understanding concerning these coal lands, it is the intention to organize in Petrograd a company capitalized for over $4,000,000 to purchase and develop the mines and claims.

Absence of Government at Spitzbergen

The conditions at Spitzbergen are unique, in that this is probably the only inhabited and promising part of the world that is under the sovereignty of no country, has no government of any kind, and no police force, courts, laws or regulations. No person or company can expect to hold or own any property or claim in Spitzbergen unless it is actually worked or occupied. In case of any claim or property being usurped by newcomers, there could apparently be no redress or damages except by the use of force or through negotiations between the governments of which the two claimants might be subjects. In June, 1914, Norway, Sweden, Denmark, Russia, Netherlands, Germany, France, Great Britain and the United States sent representatives to Christiania to organize some form of administration for the island, but they adjourned on July 30 without completing their labors. The proposed resumption of their work in February of this year was prevented by the war.

Communication with Spitzbergen is effected chiefly by means of a steamer which belongs to the American coal company and makes the distance of 100 miles between Tromsö, Norway and Advent Bay, Spitzbergen (one-third of the distance between Tromsö and the North Pole), in about 18 hr. The passage between Spitzbergen and Norway is made only during June, July, August and September, the ice around the island rendering it inaccessible

during the rest of the year. The steamer mentioned can carry a load of 3,400 tons, and makes enough passages during the four months to take away from Spitzbergen the entire annual output of coal from the American mines, as well as to bring to the island needed supplies and equipment.

Mining Conditions on the Island

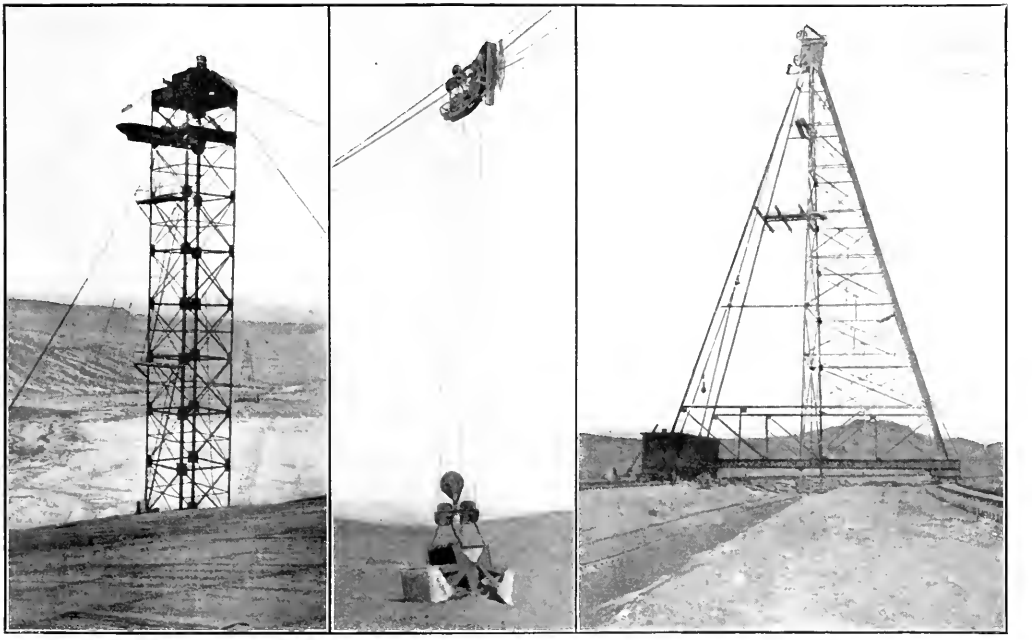
While Spitzbergen is not mountainous, the surface is broken up by hills 400 ft. to 700 ft. high. All the coal so far exploited is found above sea level. Two seams are known and worked. The mining has been so far entirely by adits, and the workings have been allowed to cave as the coal is taken out. As the seams are above sea level and the mining is through adits, there is no hoisting required and the coal can be carried to the shipping docks by gravity. The cost of mining is said to be low, notwithstanding the unfavorable conditions of climate.

As there is no timber on Spitzbergen, all the timber used for dwellings or for mining purposes has to be brought from Norway. Most of the food also is imported but there is a fairly plentiful supply of fish, seal, reindeer and white bear. The climate, notwithstanding its extreme cold, is said to be remarkably healthful, and there is little or no sickness there. Moreover, the conditions of mining are exceptionally safe, owing to the fact that explosions of gas never occur; the mines are free from water or dampness. The frozen condition of the ground and the location of the mines above sea level account for the absence of moisture. Although Spitzbergen has never been carefully explored or carefully studied except near the coast, surface indications point to the presence of many hundred million tons of coal in this remote northern part of the world.

Temporary Traveling Cableway for Tailings Reclamation

A radial traveling, electrically operated cableway of 1,290-ft. span, erected last year, according to *Engineering News*, Oct. 14, 1915, is now in operation at the Goldfield Consolidated Mines Co., Goldfield Nev., for the transportation of tailings from a large dump to the mill for re-treatment. The tailings have been dumped at the present location since 1909 and cover 75 acres.

The radial traveling tower of the cableway is 125 ft. high, and the head tower is 160 ft. high. The tail tower travels through an arc of 109° 10′ about the head, or pivot, tower. Owing to the uneven nature of the ground over which the tail tower travels, it has been found necessary to build a steel trestle in some places to carry the trackway. In the remaining portion the tracks are laid on the ground. The cableway operates a 4-line, 3-yd. Andresen-Evans bucket, weighing 9,800 lb. The cableway is operated 16 hr. per day in two shifts and delivers 1,000 tons to the mill, which runs continuously to handle this amount.



CABLEWAY FOR RECOVERING TAILINGS AT THE GOLDFIELD CONSOLIDATED MILL, GOLDFIELD, NEV.

The grab bucket digs the deposit, conveys and dumps it into a receiving hopper in front of the pivot tower, at a considerable elevation above the tower base. This hopper is mounted to move radially with the cableway travel. From this first receiving hopper a trough on a radial line delivers to the final receiving hopper.

The three-drum hoist is of the same style as three electric hoists built for the United States Reclamation Service, for use on the Rio Grande project, Elephant Butte, N. M. Each drum is 53 in. in diameter and the motor is of 300 hp., for three-phase 60-cycle current at 440 volts. The main cable is $2^{3}/_{4}$ in. in diameter.

Newfoundland's Mineral Resources

By P. B. McDonald*

SYNOPSIS—Besides important iron mines, Newfoundland has given evidences of having a wide variety of minerals. Conditions under which they may be located are easy but there has been comparatively little development, except in iron, copper and pyrites mining. The last two have been decadent until recently, but the iron mines of Bell Island, which extend under the sea, have been actually exploited by the Dominion and Nova Scotia Steel companies for over a decade.

The island of Newfoundland, which is a British colony separate from Canada, contains 42,000 sq.mi., is the tenth island of the world in size and has a population of a quarter of a million. The bulk of the people live between St. Johns and Notre Dame Bay inclusive, on the extensive coast and numerous islands of Conception Bay, Trinity Bay and Bonavista Bay. There are a few settlements on St. Marys, Placentia and Fortune Bays on the south coast, but most of the western half of the island is a barren solitude. The Reid-Newfoundland Ry., built and operated by the Reid family of St. Johns, which received enormous land grants for this construction, maintains almost daily service across the island, 546 mi. from St. Johns to Port-aux-Basques in the southwest corner, where connection is made with the Reid steamers plying across the Gulf of St. Lawrence to North Sydney, Nova Scotia—a sea voyage of nearly a hundred miles. A convenient means of travel to St. Johns from New York is by the steamers of Bowring & Co.'s Red Cross Line; steamers can also be taken at Halifax or Montreal. The sea voyage in the summer is pleasant and cheaper than by the rail route. From St. Johns to the northern bays there is good coastal-steamer service; to the south-coast ports there are occasional steamers.

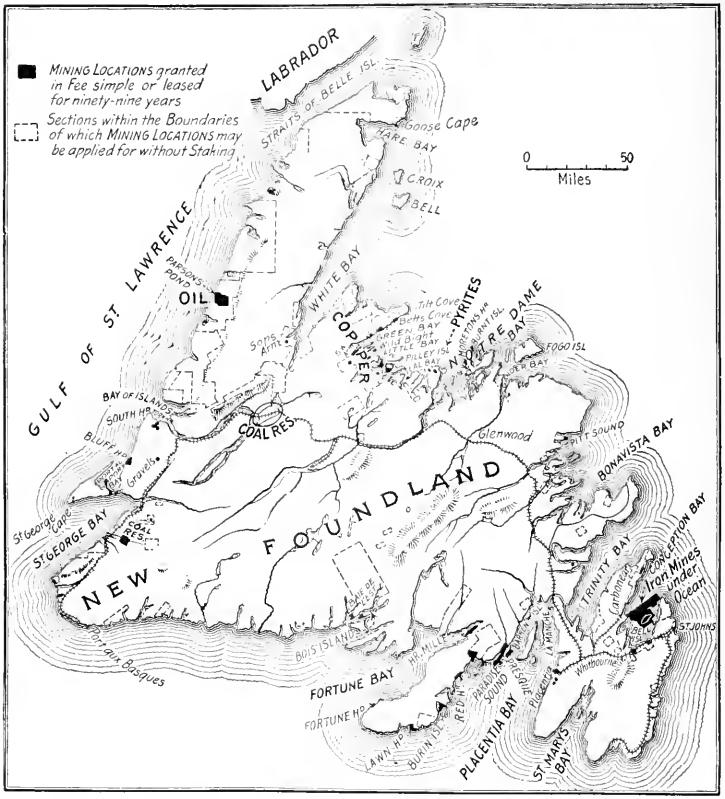
Since the European war began, both English and American mining men have taken increased interest in the opportunities for securing staple and minor minerals in Newfoundland. The principal regulations governing the taking up and operating of mining claims are:

Anyone (not necessary to be a resident) can prospect, stake or take up claims.

A claim is 1x½ mi. and is marked by one discovery stake.

Payments to the government at the Crown Land Office in St. Johns are—$10 per claim on staking and recording; $20 in one year; $30 per year for the next five years; $50 per year for the next five years; $100 per year thereafter. The expenditure of $6,000 on mining during the first five years of the lease entitles the holder of a claim to a grant in fee simple.

The workmen's-compensation law requires an operator to arrange with an insurance company to indemnify workmen in case of accidents, or satisfy the government officials of his ability to pay any liabilities incurred.



MAP OF NEWFOUNDLAND, SHOWING IMPORTANT MINING LOCATIONS

Operators should report to the government engineer in St. Johns to conform to the reasonable provisions of the mine-inspection acts.

Nearly all the minerals found in the Appalachian region have been observed in Newfoundland. Iron ore, coal, copper, oil, gold, pyrites, barytes, chrome-iron, talc, asbestos, gypsum, zinc, antimony, silver-lead and other ores have been reported, practically all close to the coast.

*Mining engineer, North Scituate, Mass

With the exception of the operations of an English company or two in copper mining in Notre Dame Bay, the iron mines of Bell Island constitute the only mineral development of any size or permanence. Since 1861, copper ore to the value of $20,000,000 has been exported. The extensive coal deposits in the southwestern part have been reported by engineers to be of excellent quality and quantity, but they have never had opportunity to prove it on a commercial scale. The petroleum fields of the west coast are believed to be valuable but attempts to drill them were mismanaged.

Bell Island and Submarine Iron Mines

The famous submarine iron-ore mines of Bell Island in Conception Bay, operated by the Dominion Iron and Steel Co. and the Nova Scotia Steel and Coal Co., can only be compared in method of occurrence and extent of resources to the slightly dipping ore seams and tremendous reserves of Red Mountain in the Birmingham Valley of Alabama, with the difference that the Newfoundland ore is of much higher grade than the Southern ore. Between 1,000 and 2,000 miners are employed in good times at these iron mines and the Nova Scotia company ships to Europe, Canada and the United States. Equipment, labor conditions and transportation facilities are first-class.

The first iron ore was shipped from Bell Island in 1895 when the Nova Scotia Steel and Coal Co. commenced work. In 1899 this company sold a part of its holdings to the Dominion Iron and Steel Co. Both companies possess large ore reserves. The latter company uses the ore in its works at Sydney, N. S. The Nova Scotia Steel and Coal Co. uses some of its own ore at Sydney and also sells ore extensively in Europe and America. J. P. Howley, government geologist of Newfoundland, estimates the Conception Bay iron ore at over three billion tons. There are in all 12 seams of ore interstratified with shales and sandstones. The maximum height stoped in the mines is 30 ft.

Copper and Other Minerals

Copper mining began in earnest in 1864 when the Union mine at Tilt Cove was opened; in 1875 the Bett's Cove mine and in 1878 the Little Bay mine were opened. All three are in Notre Dame Bay. English and Cornish miners were brought over by the Cape Copper Co. At one time this company operated a smelting plant at Tilt Cove, but it did not succeed. Much of the copper ore was shipped to Swansea, Wales, to be smelted. Other copper prospects have been worked at York Harbor on the west coast, at Bay of Islands by the Western Copper Co., and at Goose Cove in Hare Bay near the northern extremity of the island by an English company.

Gold was prospected at Mings, north of Cape St. John, in 1904-5-6; and at Sops Arm in White Bay in 1903. Several thousand dollars' worth of gold was produced at these two places. A few thousand tons of antimony ore (stibnite) was mined at Moreton's Harbor on New World Island in Notre Dame Bay several years ago. Manganese in low-grade deposits has been prospected along the south side of Conception Bay near the Reid-Newfoundland Ry. Over half a million tons of pyrites running better than 50% sulphur was taken from Pilley's Island in Notre Dame Bay between 1883 and 1907 and shipped to New York for the manufacture of sulphuric acid. Chromite was mined from 1895 to 1899 to the extent of 6,000 tons of good-grade ore near Port-au-Port Bay on the west coast; other deposits of chromite are known to exist at the headwaters of the Bay d'Est and Gander rivers, but are far inland. A lead mine at La Manche, Placentia Bay, produced 18,000 tons of ore in 1893; other operations for galena were at Lawn and Little Placentia on the same bay. In 1902-3-4, Newfoundland produced 6,000 tons of barytes; in 1904-5 talc to the amount of 6,000 tons was shipped from near Manuels, Conception Bay, to Portland, Maine. Several hundred barrels of petroleum have been pumped from the Parson's Pond oil fields on the west coast on one or two occasions since 1904.

Interior of Island a Wilderness

The interior of Newfoundland is a succession of stunted forests, desolate "barrens" and masses of rock of all shapes and sizes; it is very poorly drained and much of the surface is covered by water in one form or other. The coast line has been compared to that of Norway, being much indented by fiords and coves, which sometimes extend for surprising distances inland. The scattered population does little to alter the natural conditions of the country. The inhabitants take things as they find them and road-making, draining and building are neglected.

The drawbacks to mine developments in Newfoundland include: Lack of roads, wildness and lonesomeness of the interior, absence of interest on the part of the people in everything except fishing. The advantages are: Ocean freights, good labor conditions, nearness of the coal mines at Sydney, Nova Scotia.

How a Utah Mining Contract Was Interpreted

By A. L. H. Street*

A contract for driving a tunnel in a Utah mine gave rise to a dispute as to its proper interpretation on two points—one relating to the number of men required to be kept at work, and the other as to the right of the contractor to ore encountered in the undertaking. (Arkoosh vs. Sorrenson, 150 Pacific Reporter, 959.)

The defendant was the contractor, and his agreement obligated him to employ in the construction of the tunnel at least four men per day, working 20 days each calendar month. The plaintiffs, the mine owners, terminated the contract on the ground that men to the required number were not kept at work. The defendant, in denying breach of the contract on his part, admitted that at times fewer than four men were working, but made the ingenious claim that since an 8-hr. shift constituted a day's work it was sufficient that 80 shifts be worked in the 20 days. But the Utah Supreme Court holds that this was not sufficient, saying: "It requires no argument to show that four men who are competent miners working 8 hr. each day in a mine will accomplish more in the long run than two men working 16 hr. each day in the same mine, and especially in forcing a tunnel through solid rock." Accordingly, it is held that the plaintiffs were justified in terminating the contract for the defendant's failure to keep four men at work.

*Attorney at law, Security Building, Min[illegible]

As to the ownership of ore removed in the process, the contract provided that ore forming part of the cubical contents of the tunnel should belong to the defendant, as contractor; but he was not permitted to stope any veins, lodes or ledges without the written consent of the plaintiffs, as owners. By another provision of the contract the defendant was given "the right to drive other and smaller tunnels in any and all portions of the" claims. Under these provisions the court decided that ore taken by the defendant from an old tunnel or stope, which had existed for a long time on one of the claims, belonged to plaintiffs and not to him.

The Kenai District, Alaska

SEWARD CORRESPONDENCE

Projecting southward into the Gulf of Alaska between Prince William Sound and Cook Inlet, the Kenai Peninsula is approximately 175 mi. in length, with a maximum width of about 100 mi. Over one-half of its area is occupied by the Kenai Mountains, which rise to an average height of 4,000 ft. above sea level. The valleys are deep and relatively narrow, but in general are well timbered up to an elevation of 1,200 ft. Inasmuch as the divide is near the eastern side of the peninsula, the longer streams flow west and north, emptying into Cook Inlet or one of its arms. East of the divide the streams are frequent but short, the largest being but about 25 mi. in length. Waterfalls are numerous and water power abundant. The country rock is mainly slate or graywacke.

REGION INCOMPLETELY PROSPECTED

The Alaska Northern R.R. (now taken over by the Government), extending northward from Seward to Kenai Lake and beyond to a distance of 71 mi. from its terminal at the head of Resurrection Bay, renders accessible a region incompletely prospected as yet, but which promises to be the scene of greatly increased mining activity during the coming year. Along the route of the railroad many valuable quartz claims have already been located.

A group of claims located 4 mi. north of Seward and about 1 mi. west of the railroad has veins 2 ft. and over in width, besides many narrow stringers rich in gold. The development work consists of about 200 ft. of tunnels. Some ore has been shipped with good results. The mine has been idle this season, but the owners contemplate the erection of a small stamp mill next spring.

A group of claims located 13 mi. north of Seward and 2 mi. west of the railroad has a vein of high-grade ore between 2 and 3 ft. wide. A 100-ft. tunnel has been driven.

The Primrose mine, located 16 mi. north of Seward and 4 mi. west of the railroad, has a vein of high-grade ore with a maximum width of 7 ft. Development work consists of about 450 ft. of tunnels with connections between the upper and lower workings. There is a Little Giant stamp mill upon the property, but it has not been in operation this year.

The Blue Belle mine, adjoining the Primrose on the north, has a vein of ore similar to that in the latter mine. Tunnels have been driven to the extent of about 350 ft. A Little Giant mill has been in operation during the summer.

A group of claims located near the southwest end of Kenai Lake, about 2 mi. west of the railroad, has a vein averaging 3 ft. in width. The development work consists of opencuts and about 200 ft. of tunnel.

A group of claims located 18 mi. north of Seward, near the railroad, has a 2-ft. vein of high-grade ore. Opencuts and about 100 ft. of tunnel constitute the development.

A group of claims located 21 mi. north of Seward, near the railroad, has a vein from 2 to 4 ft. in width, which has been uncovered on the surface for a considerable distance. A 200-ft. tunnel has been driven.

The Skeen-Lechner mine, located 25 mi. north of Seward, 3 mi. east of railroad, has a vein of good ore from 2 to 6 ft. wide. There are about 1,500 ft. of tunnels, stopes and shafts. A battery of four stamps and a Lane mill have been idle this season, the property having been in litigation.

The Kenai-Alaska mine, located on the same mountain as the Skeen-Lechner, has a vein from 2 to 4 ft. wide. There are about 1,700 ft. of tunnels and stopes. A five-stamp mill has been in operation all summer, the ore being conveyed from the mine by a 6,000-ft. aërial tram.

A group of claims located 27 mi. north of Seward, 4 mi. east of railroad, has a vein of rich ore from 2 to 4 ft. in width. Development work consists of between 150 and 200 ft. of tunnels. A few tons of ore have been shipped with profitable results.

The Gilpatrick group of seven claims, located 29 mi. north of Seward, 15 mi. west of the railroad, between Slate and Summit Creeks, has several veins of rich ore from 1 to 5 ft. in width. About 600 ft. of tunnels have been driven. An arrastre on the property has been used at intervals during the present summer. Felix Brown, of Seattle, who has an option on these claims, has taken out some exceptionally rich ore recently and proposes to erect a stamp mill and tramway next season.

An extension of the Gilpatrick claims was located this season by Messrs. Skeen and Stevenson, who subsequently gave an option to J. Ronan. The vein, while narrow, is extremely rich as far as it has been exposed.

DREDGING ON SIX-MILE CREEK

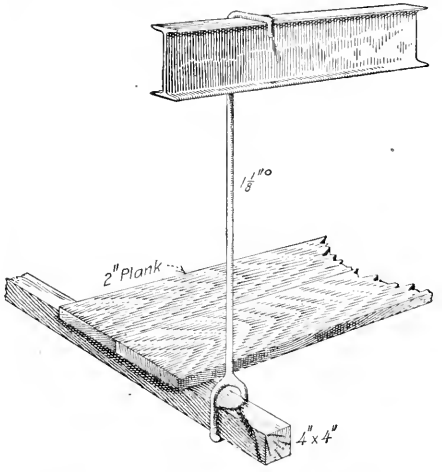
Most of the placer operations on the peninsula have been confined to the northern portion west of the divide. Charles Herron has been dredging on Six-Mile Creek near Sunrise, but has been bothered considerably by the presence of large boulders. On Resurrection Creek near Hope, several small hydraulic plants have been in operation. Among other operators might be mentioned the Matheson Bros., who have recently brought in a steam shovel for the purpose of excavating a ditch to increase the water-supply, and Gus Seiffert, who has been operating with good results upon the ground adjoining the Mathesons' property. Numerous small operators have been working upon the streams mentioned, on Bear Creek, on Cañon Creek, on Cooper Creek and on various streams draining the Kenai Lake area. The quality of the gold recovered varies considerably, that secured from Bear Creek running about $15 per oz., while that taken from Cooper Creek runs as high as $17.50 per oz.

Venezuelan Mineral Exports in 1913 have been officially reported as follows: Asphalt, 81,651,224 kg.; copper ore, 15,358,602 kg.; gold, 732 kg. The increase in asphalt exported was more than 30,000,000 kg. over the previous year.

Details of Practical Mining

Staging Hangers for Riveters on Structural Work

Slinging a staging for riveters on structural ironwork is too often done with ropes, which are both unsatisfactory and unsafe. A cheap and convenient hanger, shown in the accompanying sketch, is made of 1⅛-in. round iron, with a large eye at the lower end and a hook at the upper end to hook over the I-beams or other structural members. Through the eye is inserted a 4x4 timber on top of which



STAGING FOR STRUCTURAL-IRON WORKERS

2-in. planks are laid, and the result is a perfectly safe, convenient and satisfactory staging. The cost of these hangers is small, they are light and can be handled easily, and they are not liable to destruction and can be used on any subsequent work.

Electric Squibs for Igniting Black Powder*

Electric squibs for black powder, as manufactured by the Du Pont company, consist of a paper shell, in one end of which is fastened the igniting composition and the insulated copper or iron wires, the other end being open. The paper shells are made in the shape of a truncated cone, in order that a blasting cap may be inserted in the shell and be more tightly wedged the farther it is inserted. It is therefore not necessary to crimp the blasting cap in the shell.

Without the blasting cap these squibs are used to ignite blasting powder electrically, but they can be used to detonate dynamite by using them with a blasting cap. By their use, it is possible to ignite a charge of blasting powder in the center, the ideal position, which secures the maximum efficiency of the explosion, impossible with either fuse or miner's squibs.

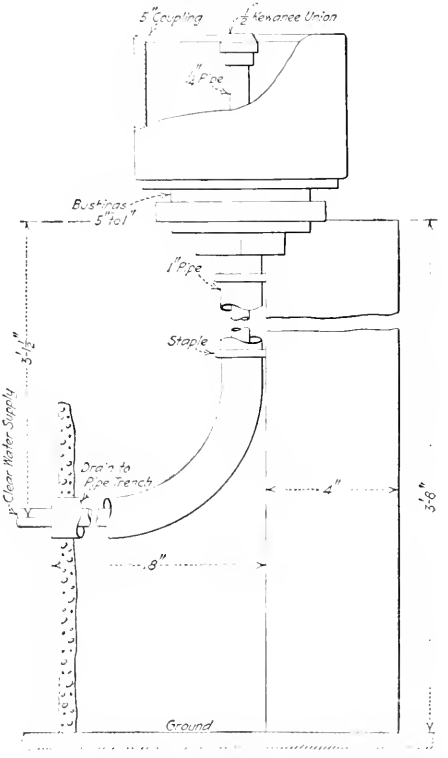
Several charges can be ignited at the same time if desired, with a considerable saving of explosives. Then, too, the charges can be ignited at the time desired and when everyone is in a safe place. They are as cheap as fuse and said to be far superior.

*From information furnished by the manufacturers.

Drinking Fountain for a Mine

By D. E. Charlton*

The fountain illustrated herewith is simple in construction, applicable for underground or surface use and may be made from material generally on hand at the



A SIMPLE DRINKING FOUNTAIN

mine. The cup is made of a 5-in. coupling, although smaller sizes may be used. This is fitted with bushings at the lower end and reduced to connect with a 1-in. pipe which acts as a drain, taking care of the overflow of water. The fresh water enters through the ¼-in. pipe that passes

*Mining engineer, Virginia, Minn.

through the 1-in. pipe, as shown in sketch. The male end of a Kewanee union will serve as a suitable nozzle if placed on the end of the ¾-in. pipe. The apparatus is firmly supported and held to a wooden post by means of staples.

Scheme of Diamond Drilling at White Pine

The extensive drilling campaign at the White Pine Extension is rapidly nearing completion. Some months ago the company let a contract for 75,000 ft. of diamond drilling, the largest single contract for drilling ever let in the copper country.

The work was laid out on broad lines and this plan has been strictly adhered to. It consisted of one line of holes, spaced 1,000 ft. apart, to cut the copper-bearing beds at a depth of about 400 ft. from the surface on their dip; a second line of holes, spaced 1,000 ft. apart, to cut the beds at a depth of 800 ft.; and a third and final line of holes, 1,000 ft. apart, to cut the beds at a depth of 1,200 ft. The second line of holes was located halfway between the holes of the first, and the holes of the third line were placed 250 ft. from the second. When this drilling is completed, therefore, it will give lines of holes along the strike at intervals of 250 ft., 250 ft. and 500 ft., then repeating this sequence, cutting the formation at depths of 400 ft., 800 ft. and 1,200 ft., respectively.

To date, the lines of 400-ft.-deep and 800-ft.-deep holes have been completed for a distance of 15,000 ft. (nearly three miles) along the strike. In all these holes not a single one failed to disclose commercial copper rock. The first hole on the 1,200-ft.-deep line is completed and shows the same character of formation with the same copper content. In this hole the copper-bearing shale bed shows an increase in thickness of 33⅓%, but with no noticeable difference in copper assay.

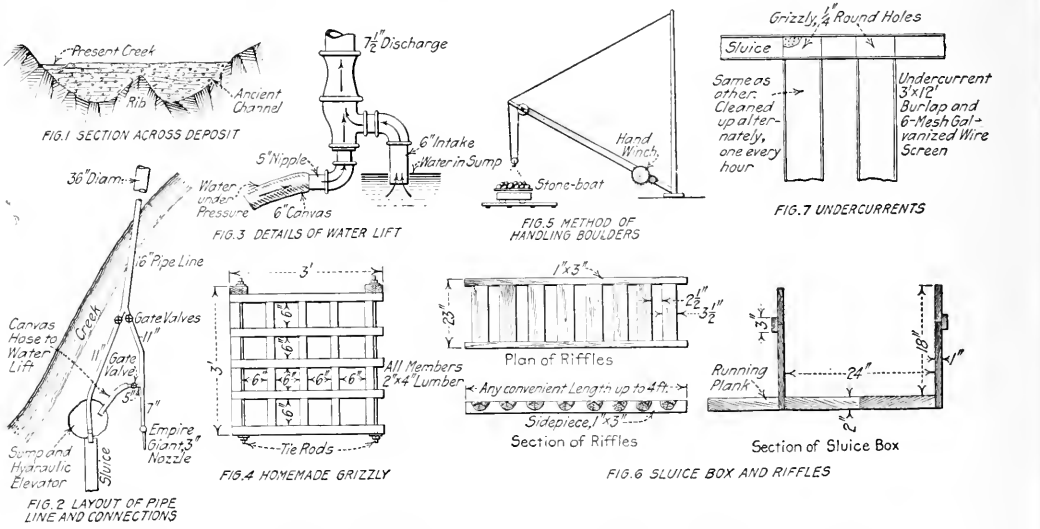
The drilling will be completed when the remaining 1,200-ft.-deep holes are finished. There are four drills working two shifts each on these deep holes at present. There are six drills altogether working on the property. Including the time lost in moving, the drills make about 50 ft. each per day of 24 hr.

Within 60 days the drilling will be completed. Active mining operations will then start with the sinking of one large four-compartment shaft.

Gold Bar Hydraulic Mine

By Hubert I. Ellis*

Gold mining in the state of Washington, outside the Republic district, has never attained great importance. Blewett, Swauk and certain deposits in the Cascades proper have made small productions from time to time, but the industry has been at a standstill for a number of years, with no prospect of immediate improvement. The Blewett district, with a total production variously estimated at three quarters of a million to two million dollars, is practically dead at present, except for the Gold Bar hydraulic mine.



FIGS. 1 TO 7. DETAILS OF EQUIPMENT AT GOLD BAR HYDRAULIC MINE, BLEWETT, WASH.

To cut the beds at a depth of 800 ft.; and a third and final line of holes, 1,000 ft. apart, to cut the beds at a depth of 1,200 ft. The second line of holes was located halfway between the holes of the first, and the holes of the third line were placed 250 ft. from the second. When this drilling is completed, therefore, it will give lines of holes along the strike at intervals of 250 ft., 250 ft. and 500 ft., then repeating this sequence, cutting the formation at depths of 400 ft., 800 ft. and 1,200 ft., respectively.

To date, the lines of 400-ft.-deep and 800-ft.-deep holes have been completed for a distance of 15,000 ft. (nearly three miles) along the strike. In all these holes not a single one failed to disclose commercial copper rock. The first hole on the 1,200-ft.-deep line is completed and shows the same character of formation with the same copper content. In this hole the copper-bearing shale bed shows an increase in thickness of 33⅓%, but with no noticeable difference in copper assay.

The Gold Bar group includes four placer claims on Peshastin Creek, extending downward from the town of Blewett, which is reached by an 18-mi. stage road from Leavenworth, a station on the Great Northern Ry. A large proportion of the gravel consists of big boulders that interfere greatly with hydraulicking. Work has been started at the lower end of the group of claims, where the gravel deposit is divided by a central "rib" of rock, as shown in Fig. 1. It is planned to work the ground on the right-hand side of this rib first and then to divert the creek into the worked-out portion and mine the other half.

*Mining engineer, Kellogg, Idaho.

Water is obtained from Peshastin Creek, which has rather a high gradient, and is carried by flume along the left limit of the creek to the upper end of the pipe line, which is 1,600 ft. long. The diameter of the pipe at the intake is 36 in., decreasing to 16 in. where it branches, as shown in Fig. 2. The head is very low for the heavy gravel, being only about 75 ft.

During spring and early summer, when there is an abundance of water from melting snow, it is planned to use a 3-in. Empire giant and a hydraulic elevator for raising the material to the sluice boxes. After the cut has been started, small sluice boxes will be placed in it when water is low and the gravel will be shoveled in by hand. A rough wooden grizzly with 6-in. spaces (Fig. 4) is placed before the elevator intake to prevent clogging by boulders too large to pass the neck. A small water lift, details of which are shown in Fig. 3, has been installed in the cut to remove excess water. Large boulders are removed by means of a 3x4-ft. "stone-boat" and a truck running on a wooden track. The stone-boat is loaded in the cut and swung on the truck by the hand winch and boom shown in Fig. 5. Larger boulders are lifted by chains without the stone-boat.

The main sluice consists of seven boxes and two undercurrents. The boxes are 24 in. wide and 18 in. deep, and are set with a grade of 5 in. to the box length, 12 ft. Transverse riffles hewed from round poles, 3½ to 4 in. diameter, are employed. Details of boxes and riffles are shown in Fig. 6. The undercurrents, Fig. 7, are of the usual transverse type and are 3 ft. wide by 12 ft. long. The grizzlies are of sheet iron punched with ¼-in. round holes. For saving fine gold the undercurrents are fitted with burlap held down by 6-mesh wire screen.

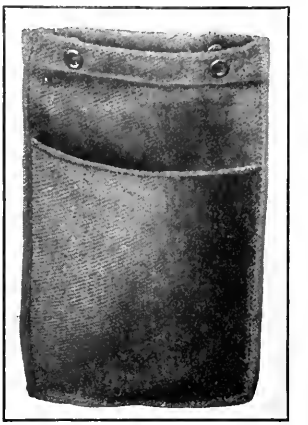
The success of this enterprise—the management of which has shown considerable ingenuity in dealing with local conditions in such manner as to limit the capital outlay as much as possible—depends of course on the gold content of the gravel. Owing to lack of preliminary prospecting, made difficult by the nature of the material and the abundance of water, the operators considered it advisable to go ahead on a small scale, doing all their own work, as far as possible, until the feasibility of working the ground at a profit has been demonstrated. The small extent of the deposits, the abundance of large rocks, the uncertainty of the water supply, the low head at present available and the necessity of shutting down during winter are the chief difficulties in the way of successful operation. George Dennison, one of the partners, is the manager.

Peculiar Accident at an Old Butte Mine

Overcome by foul air, the presence of which he did not suspect, and falling from a ladder when not more than 8 ft. from the surface, Frank Romaldi was killed Aug. 24. He recently went to Butte to go into the leasing business with two partners. They heard that the Little St. Lawrence mine in Northwest Butte was to be had and went out to investigate the shaft. Romaldi concluded to try the ladder while his partner watched him descend. Romaldi's candle went out when only 8 ft. below the surface; he let go his hold and with a scream for help shot into space. Realizing that the shaft was full of foul air, Romaldi's partner called for help, and a first-aid team was sent from Anaconda mine. Two men equipped with Draeger helmets descended the shaft, tied a line around Romaldi's body and brought it to the surface. The body was only slightly injured, showing that death was caused by suffocation.

Bag for Dynamite and Fuse

Wallace McKechan, safety inspector of the Copper Queen Consolidated Mining Co. and a leading member of the American Mine Safety Association, with the approval of the central safety committee of the company, recently designed the bag here illustrated for the carrying of powder and fuse. The sack is made of heavy jute and is sewn with flax thread, so that it is exceptionally durable. From 50 to 70 sticks of dynamite can be carried in the bag proper, the fuse being placed in the outside pocket. Large brass eyelets are fastened into the top of the sack for convenience in handling and carrying. It was noted by the management of the Copper Queen mines that all dynamite when handled in quantities of less than a box was carried in any way which would suit the convenience of the miner, it generally being tied together with a piece of fuse. Capped fuse was carried in the miner's hand or wrapped around his hat or thrust loosely in his shirt front. All these methods were exceedingly dangerous, and since the bag has been introduced these bad practices have ceased. The sack is made by the Bemis Bros. Bag Co., St. Louis, Mo., and sells for 35c. in 100-bag lots. The size of the bags is 15x22 in. outside measurement.



BAG FOR EXPLOSIVES

Shoveling and Tramming in the Joplin District*

In the zinc-lead mining district at Joplin, Mo., broken rock or dirt is shoveled into buckets of from 1,000- to 1,650-lb. capacity. Most of the dirt is small enough to be handled with a shovel. Boulders that cannot be broken with a sledge are broken with powder, this practice being called "boulder topping." The shovelers, or "cokeys," as they are called, are paid by the bucket, and they load all the way from 30 to 70 or 80 buckets in 8 hr. There are some records of 90 and 100 buckets per shift. The average for all of the sheet-ground mines is 22 tons per 8-hr. shift per shoveler. Usually the shoveler trams his buckets or small trucks to a switch or lay-bye, where they are later collected and hauled to the shafts by mules.

Details of Milling and Smelting

Zinc in the Cyanide Mill

By A. Dorfmann*

The high price of zinc, in both shaving and dust form, has been causing cyanide operators considerable anxiety since the breaking out of the European war. Since it is fairly well-known that a great deal more zinc is used than is theoretically required for precipitation of gold and silver contained in solution, some method of economizing it has been made the object of a great deal of study. Some have attempted to accomplish the same result by recovering the zinc from precipitate. This article gives the result of some experiments that I carried out at the McIntyre-Porcupine mill in the Porcupine gold district of Ontario. While it does not point toward a remedy for the difficulties encountered, it does show what is actually taking place in the mill. I refrain from comment or suggestion, but merely put these facts in the form of tables and as briefly as possible, hoping that they may suggest some scheme of improvement to those who may be considering the subject.

EXPERIMENT DATA ON ZINC IN CYANIDE SOLUTIONS

Period of experimenting	June 1st to 7th, 1915, inclusive
Ore treated	2,040 tons
Solution used in Hardinge ball mills	2,040 tons
Solution used in closed circuits, tube mills and classifiers (overflow being 71.36% moisture)	5,013 tons
Solution used in agitators	5,013 tons
Pregnant solution sent to precipitation	4,703 tons
Solution sent to decantation units: 1,098 tons solution, primary-thickener underflow, 35% moisture; 4,703 tons barren solution	5,801 tons
Solution discharged with tailings (35.7% moisture)	729 tons
Zinc dust used (dried at 212° F.)	984 lb.
Precipitate (dried at 212° F) recovered	735 lb.

Samples of solution were taken every 24 hr. in proportion to the quantities treated, and at the end of 7 days combined and mixed thoroughly. All zinc determinations were made by potassium-ferrocyanide titration with uranium nitrate as indicator.

ANAYLSIS OF SOLUTIONS USED IN EXPERIMENTS

	Zn. per Ton of Solution
Storage	0.213 lb.
Hardinge discharge solutions	0.157 lb.
Classifier overflow	0.157 lb.
No. 2 Agitator	0.147 lb.
Pregnant solution	0.158 lb.
Barren solution	0.308 lb.
Tailing solution	0.125 lb.
Au precipitated from each ton of solution	$3.658
Or 832.31 oz. or	57,400 lb.
Ag precipitated from pregnant solution	17,393 lb.
Theoretical amount of zinc necessary to precipitate total gold	19 lb.
Theoretical amount of zinc necessary to precipitate total silver	6,178 — 25,178 lb.
Commercial zinc dust used contains	95.04% zinc
Zinc content in 984 lb. used	935.19 lb.

CONSUMPTION OF ZINC IN VARIOUS DEPARTMENTS

1. According to Solution Analysis:		
Barren solution shows an increase of 0.150 lb. per ton of solution. As 4,703 tons was precipitated, the amount of zinc dissolved in press was	705 lb.	
Zinc wasted through secondary reactions	75.4%	
2. According to Precipitate Analysis		
Precipitates contain 32.5% total zinc. As 735 lb. was recovered, the amount of zinc left in press	239.38 lb.	
Zinc dissolved in press (935.19—239.38)	695.81 lb.	
Zinc wasted through secondary reactions	74.4%	
3. According to Zinc Precipitated from Solutions in Mill Operations:		
Zinc precipitated in Hardinge mills (2020x0.231)—(2040x0.157)	150.96 lb.	16.14%
Classifier overflows, 5,013 tons, composed of 2,040 tons Hardinge-mill discharge solution at 0.157 and 2,973 tons of storage at 0.231, equals 5,013 tons at 0.2009 lb. (5,013x0.2009)—(5,013x0.165)	179.96 lb.	19.24%
Zinc precipitated in agitators (5,013x0.165)—(5,013x0.147)	90.234 lb.	9.65%
Zinc precipitated in decantation* system: 4,703 tons barren solution at 0.308 lb. and 1,098 tons at 0.158 lb.—5,801 at 0.2796 (5,801x0.2796)—(5,801x0.231)	281.928 lb.	30.15%
	703.082 lb.	75.18%

* Includes amount of zinc (91.12 lb.) discharged as soluble zinc salt

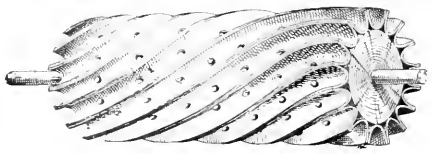
A New Conveyor-Belt Brush

By K. S. Clarke*

The conveyor belts in a Dwight-Lloyd sintering plant treating flue dust, ore fines and flotation concentrates gave trouble because of material adhering to them. Bristle brushes wore out quickly and were unsatisfactory, but after cutting off the bristles and tacking on strips cut from old conveyor belting, as shown in the sketch, we had no more trouble.

The belting should be stiff enough to spring well, so the blades will be stiff and remain in position. The spiral curve is short, and at least three blades are in contact



DEVICE FOR CLEANING CONVEYOR BELTS

with a 16-in. belt at once. The height of the blades—2 in.—and the distance apart—2 in.—allow for wear, necessary flexibility to save belt wear, and self-cleaning of the brush. The drive is by sprocket and chain from the head pulley.

Converting Leady Copper Matte at El Paso, Tex.

The direct conversion of the high-copper matte made in the lead furnaces of the El Paso Smelting Works, El Paso, Tex., has been carried out for some time in the copper department of this plant. The concentrated matte was formerly shipped to Omaha where the lead contents could be recovered in the baghouse, but the expenses for freight and treatment were higher under certain conditions than the value of the lead recovered. With the installation of a large oil-fired settler for the lead furnaces at El Paso, the collection of the matte was facilitated and the economy of direct conversion greatly increased.

High copper in the leady copper matte—Cu 19.8%, Pb. 12.1%—is characteristic of the usual conditions at the El Paso plant. It had long been customary, according to H. F. Easter,† to set aside matte of this grade until a sufficient amount had been accumulated to make worth while a concentration run. The matte produced during these campaigns usually averaged about 10% Pb and 35

*Coniston, Ont.

†Excerpts from a paper entitled "Lead Smelting at El Paso," presented at the San Francisco meeting of the American Institute of Mining Engineers, September, 1915.

to 40% Cu. It was drawn off in handpots, cold dumped, broken by hand and resmelted through the copper-blast furnaces. All this involved considerable expense and it became evident that much of this could be saved if some means were provided for getting this molten leady copper matte direct to the converters. The oil-fired settlers offered a convenient reservoir in which to collect the matte in fairly large quantities, and a pit 10 ft. wide and 8 ft. deep was dug directly in front of the settlers in order to allow the approach of the 5-ton matte ladles serving the converters of the copper department.

The direct conversion of the leady copper matte proved to be such an economy that since the introduction of this system matte has been converted that is much lower in copper than formerly. At the time of writing it was customary to figure the value of the lead contained in the leady copper matte, and therefore lost in converting, as against the cost of roasting and resmelting in the lead furnace, taking into consideration the fact that each unit of copper present means the loss of a certain amount of lead even on a concentration run. Each day's production of leady copper matte is thus disposed of according to its assay, either direct to the converters or poured on the ground in beds, to be picked up, crushed and roasted. As the matte has recently been rather low in lead, most of it has gone direct to the copper converters even though it may not run higher than 20% copper.

Condensing Silver-Refinery Fume by Cottrell Process

In a recent paper before the American Electrochemical Society, Charles H. Aldrich described the experience of the Raritan Copper Works, Perth Amboy, N. J., in using the Cottrell process in the treatment of silver-refinery furnace gases. The gases pass from the doré furnaces to a 4-ft. sheet-iron flue about 40 ft. long, then into a brick flue 6x7½ ft. by 20 ft. long. From this a centrifugal fan driven by a 40-hp. motor delivers the gases tangentially into a settling chamber 16 ft. in diameter by 17 ft. high. An iron flue leads thence to a brick flue, which in turn leads to scrubbers, the Cottrell treater being attached to the scrubber outlet. This Cottrell treater had for its electrodes lead plates and bars (sharpened on the edges).

In this treater a product was recovered assaying: Se, 6.5%; Te, 6%; As, 19%; Sb, 28%; Pb, 9%; Bi, 2%; Cu, 0.9%; Ag, 800 oz. per ton; Au, 1 oz. per ton. The silver condensed amounted to 29.2% of the entire dust-system recovery; the gold to 6.6%. Of the silver treated in the furnaces it was 0.24%; of the gold, 0.022%.

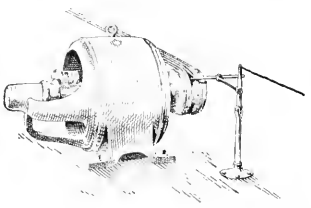
The volume of gas was about 6,000 cu.ft. per min., which required 2.5 kw. at 35,000 to 40,000 volts. One man for two or three hours a day is required to look after the treater. Results on the dry gases coming direct from the furnaces have not been so satisfactory as when the scrubbers were working. The gas temperature with the scrubbers is about 150° F. and about 300° F. without them. The presence of suspended moisture seems to be a very desirable condition but the injection of steam did not give satisfactory results.

However, in building a new treater Mr. Aldrich decided that better results would be obtained in a pipe-shaped treater with a central lead electrode, this metal withstanding both the chemical corrosion due to the gas and fume and electrolytic action. The pipes were 18 in. in diameter by 12 ft. long, made of lead. The discharge electrodes were ⅞-in. steel shafting covered by extrusion with a star-shaped layer of lead. With this apparatus and a voltage of 85,000 to 90,000, over 99% precipitation efficiency has been obtained at a gas velocity of 4.5 ft. per sec. As the remainder of the flue and scrubber system was not changed when the Cottrell treater was added, it appears that the savings given are all a net gain, after deducting costs of working the Cottrell apparatus and the cost of re-treating the fume.

A Failing-Rope Indicator

Machines at the Bunker Hill & Sullivan Mining and Concentrating Co.'s mill at Kellogg, Idaho, are driven by electric motors, most of which are equipped with rope drives. The experience has been that often a rope will commence to fail and unstrand, and before anyone notices it, the loose strand has become wound up in the pulley or shafting and serious damage results.

In order to avoid catastrophes of this sort, a simple scheme has been devised to indicate instantly the beginning of failure of any of the ropes. The scheme is shown in the accompanying sketch. Just back of the motor pulley is placed a stand with a vertical rod hinged so as to be movable backward. An adjustable arm is held by this rod and pedestal and is placed near the revolving pulley. Should one of the rope strands come loose, it will strike the arm a sharp blow, bending it backward at the hinge and loosening the string which is attached to a switch controlling the current. This bending back immediately opens the circuit, cuts off the current and stops the motor. In this way an entirely automatic safeguard is provided, so that no danger is incurred through rope failures.



AN INDICATOR OF FAILING ROPES

Separating Nickel and Copper Electrolytically

In one of N. V. Hybinette's recent patents on the electrolytic separation of nickel and copper, he declares that the inconvenient cathode reactions resulting from the presence of ferrous and ferric salts may be avoided by putting the cathode in a porous cell, and conducting the circulation entirely through the anode compartment (U. S. Pat. 1,123,299). This cathode compartment has a diaphragm of so loose a texture as to be rather a filter than a diaphragm, for instance, a double-walled lead screen having a filling of asbestos. The current is led into and out of the anode compartment. The rate of plating out the copper and of circulating the electrolyte must of course be regulated according to the porosity of the diaphragm.

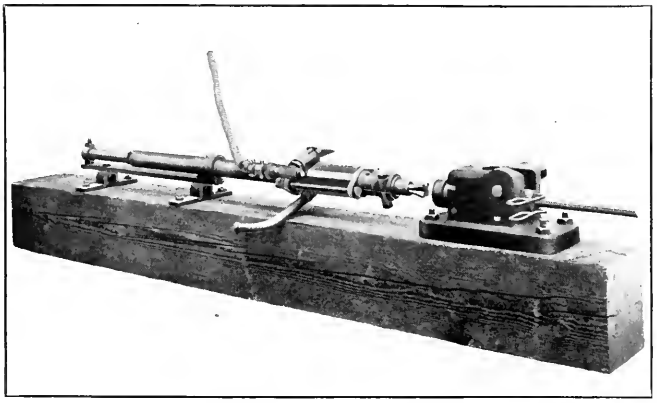
Another patent (U. S. Pat. 1,128,315) designed to lower the amount of circulation required feeds the circulation into the cathode cell, but alternately to its top and bottom.

Mining & Metallurgical Machinery

Machine for Collaring Hollow Drill Steel

The greatest drawback to the use of collared drill steel by the small mine has been the difficulty experienced in forming the collar on new steel. The small user of collared drills has been forced to have his steel made up outside or has been driven to the unsatisfactory expedient of welding a collar on the outside of his steel, which gave indifferent service. The Denver Rock Drill Manufacturing Co. is putting out a collaring machine, so-called, which is really a small and inexpensive device to be used in connection with a stoping drill, both of which are mounted on a piece of large timber by lagscrews, as shown in the accompanying illustration. Any size of drill steel can be used by securing the proper-sized dies.

The drill steel, after being heated for about 6 in. on the end, is placed in a solid movable die and is held in the machine in a split die by a vise wedge. Having gripped the steel firmly in the split dies, the operator by means of the stoping drill mounted in front of the device, gives repeated blows upon the head of the movable die until the shoulder comes up against the face of the machine, when the collar is completed.



DRILL-STEEL COLLARING MACHINE

The device is so simple and so well within the means of the smallest mine that it should find a broad field.

An Improved Vacuum Pump

A new and improved vacuum pump has been designed and built by the Ingersoll-Rand Co., following in general the principles of the "Imperial" air compressors. The principal details are the valves, which in this machine are of the mechanically-moved corliss type; the clearance, which has been reduced to the minimum by making the valve partly fill the port in the cylinder head; and extremely complete water jacketing. The manufacturers claim that these refinements of design enable the maintenance of a vacuum within ½ in. of barometer.

The device occupies less floor space than machines of the straight-line type of similar capacity, because of duplex operation and higher speed. They are built in capacities from 798 to 7,048 cu.ft. per min., both for atmospheric and low-pressure (5 lb.) discharge.

Jeffrey Quad Truck at Victor*

The Portland Gold Mining Co., of Victor, Colo., has recently taken over Stratton's Independence and uses a Jeffrey Quad and a 5-ton truck of another make for haulage. The work consists principally of hauling shipments (less than carload) of miscellaneous supplies from the freight depot in Victor, Colo., up a considerable grade to the various plants on different parts of Battle Mountain in the Cripple Creek district. The grades are heavy, and except for a few months in the summer, the road conditions are as a rule bad.

The operating costs of the Jeffrey Quad for June and July, 1915, were as follows: June, 1915—Gasoline and oil, $42.56; blacksmith labor, $1; miscellaneous labor in maintenance, $22.63; supplies, $1.13, or $67.32. July, 1915—Gasoline and oil, $48.97; supplies, 25c.; miscellaneous labor in maintenance, $10.69, or $59.61.

These figures are for a period during which the Jeffrey truck was doing practically all of the hauling at the mine. There is no record available at the present time of the cost per mile for tires and gasoline, but under Victor conditions both would be heavy.

The other truck, which the company has had for several years, has given remarkably good service, considering the conditions under which it has had to operate. However, at the mine the sentiment seems strongly in favor of the Jeffrey Quad for the following reasons:

The Quad truck will carry its rated capacity and deliver it in places where the other truck will not go at all, whereas the latter, with a rated capacity of 5 tons, cannot carry over 2 tons up the hills at the mines. The Jeffrey truck has not been laid up for repairs during working hours for more than 20 min. at a time from Jan. 1 to the middle of August. It is also found that the Jeffrey machine will make faster time than the other car, and further, that it will operate in deep snow at times when the other machine cannot be used at all.

A New 15-Ton Heroult Electric Steel Furnace is to be installed by the United Steel Co. in its works at Canton, Ohio, where it already has a 6-ton furnace in operation.

Correspondence and Discussion

Timbering in New York Subway

In reference to Percy E. Barbour's article in the *Journal* of Oct. 2, on subway timbering in connection with the recent accidents on Seventh Ave. and on Broadway, I agree with Mr. Barbour that the employment of mining engineers in subway work would be advantageous. Their experience would qualify them to meet conditions arising in this class of work. But to quote from the article:

> These subways are being constructed with as little interference to surface traffic as possible. This is accomplished by digging up the surface of the streets, laying heavy timbers and on top of these placing heavy planking, and then, in effect, stoping out the ground underneath these timbers and catching them up on vertical bents or sets with long vertical legs. These excavations vary in depth, and in the two sections where these accidents have occurred they were from 30 to 36 ft. below the surface of the street. Were it not for the fact that street traffic is allowed above excavations, it would simply be an opencut proposition, but with the load being carried on the timbers above it is strictly analogous to underground stoping, with the hanging wall flat but offering very little weight, not nearly so much as would be the case in any ordinary mining operation requiring timbering. The height of this excavation would not be greater than an ordinary four- or five-set stope.

Farther along in the article is a sketch of the timbering at the scene of the Broadway accident and the following comment:

> The timbering as shown in Fig. 2 cannot be said to approach square-set timbering in any way, but it does indicate that square-set timbering could have been used without any inconvenience to subsequent construction—in the way of putting in concrete piers or erecting the steelwork for the permanent structure. This would have afforded complete security against the fall of rock which caused the second accident and would have prevented the collapse of the entire structure if it had been used at the scene of the first accident. Thus two serious accidents causing much damage and loss of life have occurred through overlooking the precautions taken by the miner in his everyday work when confronted by similar problems.

While I do not understand from the foregoing that Mr. Barbour recommends square-set timbering for subway work, he suggests the close analogy between subway timbering underdecking, and underground stoping. I would therefore like to analyze conditions met with in the two cases and point out that square-set timbering could not be adapted to subway use.

Square-set timbering is composed wholly of compression members fitted together to resist pressure from all sides and is locked in position by blocking and wedging against the roof and walls of the opening. It is intended primarily to prevent the fall of rock from the roof and walls, but when reinforced by rock filling will resist heavy pressures. It is not, however, a self-contained structure that would stand alone, unless the members were diagonally braced and tied together. Subway timbering has to be a self-contained structure to a considerable degree, especially in rock cuts. There are the side walls to wedge the structure against, from the floor of the cut, up to the cellar-floor level of the street buildings; and there can be additional bracing against the abutments at the two ends of the excavation, in so far as such bracing would not interfere with excavating operations. Overhead, however, there is only the comparatively light street-structure load, including the weight of pipes and ducts, to wedge against; and the vibration of street traffic tends to shake the entire structure apart.

To use square-set timbering for subway work therefore, from the standpoint of security alone, would mean that the structure could not be securely wedged together and the consequent necessity of a prohibitive amount of tying and diagonal bracing. Also it is obvious that the use of continuous transverse members from side to side of the excavation would be more secure than transverse members built up of short-length members tied together, as would be the case in the employment of the transverse members in square-set timbering.

But there are other practical reasons why square-setting would not apply to subway work. The street decking, tracks and subsurface pipes, sewers and ducts, temporary and permanent, require a special transverse spacing arrangement of posts under the longitudinal joists and beams supporting them, and this spacing does not conform approximately to the regular posting of square-sets. These posts, irregularly spaced transversely, are placed in rows 10 ft. apart longitudinally in the excavation and rest on transverse members which distribute the street-structure loads, in order that a more regular system of posting may be used under the transverse members; also that fewer posts may be employed, so as to interfere to the least extent possible with excavating operations in the lower part of the cut. The 10-ft. longitudinal spacing of posts and transverse members in bents is to conform to construction requirements in erecting the permanent steel bents which are spaced on 5-ft. centers. The timber bents are placed in the center of alternate steel bays, except in the deepest excavations, where 5-ft. spacing of the timber bents is used.

In addition the transverse cross-sections of subway cuts vary constantly, owing to the change of depth of the excavation and, generally, to the constantly varying relative grades of the pairs of local and express tracks. The tracks are in some places all on the same level; in other cases one pair or the other is elevated or depressed, and occasionally one pair is superimposed over the other. These variations compel special arrangements of the cross-members and posts.

From the foregoing it may be seen that in subway timbering nothing like the regular arrangement of members, as in square-setting, could be approximated. The only members of constant length would be the horizontal struts between bents, and only a comparatively few of these are required and of much smaller cross-section than the transverse members and posts. The upper tiers of posts in the bents do not line in with the corresponding lower tiers, which makes necessary the use of continuous transverse members to distribute the loads. There is the added advantage in this arrangement, that continuous transverse members make a more secure structure than would be possible in square-sets.

The best practice in subway timbering therefore includes continuous cross or transverse members to distribute loads, to brace the sides of the excavation and to tie the structure together more securely; the requisite rangers and lagging or sheathing to hold the sides of the excavation; sufficient posting in all tiers and secure vertical diagonal bracing, both transversely and longitudinally, of all tiers of posts; sufficient struts or spacers and adequate street structure. JOHN SEWARD.

West Nutley, N. J., Oct. 7, 1915.

Although Mr. Seward in his communication on the subject of "Timbering in New York Subway" agrees with me as to the advantage of employing mining engineers for handling mining-engineering problems in subway work, he seems to have missed the point of the argument, and in his communication loses himself in a detailed discussion of the timbering, which he views solely from the point of the subway engineer; he, himself, having designed one section of subway timbering, according to a letter in the *Tribune*.

I do not want to enter into a discussion of the details of square-set timbering, but would call his attention to the following in the editorial columns of the *Journal* of Oct. 9: "We are not to be understood as recommending that the New York subways during construction ought to be timbered by the square-set method. Without any doubt a study of the problem would result in the development of a special method which might be a modification of the square-set system."

My citation of the square-set system of timbering developed on the Comstock lode more than 40 years ago was intended to show that there was no excuse for not providing an adequate system of timbering in the subway, inasmuch as mining men have known for more than 40 years how to support the most difficult kind of ground. The system of bents used in the section of the subway under discussion, together with the girts between the bents, suggested in a remote way square-set timbering, but emphasized in a distinct way that the subway engineers did not use the judgment which the mining man shows in putting in timber.

The statement that square-set timbering "is not a self-contained structure" applies only if one considers it in the nature of a house, which it is not. Square-set timbering underground is certainly self-contained when it is properly wedged in place and it is not intended to be used any other way. But square-set timbering *per se* is not recommended, as has been already stated.

He also states that "it is obvious that the use of continuous transverse members from side to side would be more secure than transverse members built up of short-length members tied together." Theoretically true, perhaps, but 60-ft. members such as would be required in the subway are a scarce article. Apart from the mere physical difficulties on this point, which will be passed over just now, whether a continuous transverse member from side to side of the excavation would be better than square-setting need not be discussed, since what was used does not come within the definition. As per the sketch in my article quoted (reproduced on page 689 of this issue), the only long transverse member used was one composed of two 24-in. I-beams at the ends connected by two 12-in. channels in the middle and this construction, as well as the entire framing of the bents, using only one short diagonal brace (*A*), not only invited "jack-knifing" of the structure, but got it.

The communication states that square-set timbering requires "a prohibitive amount of tying and diagonal bracing." No definition of "prohibitive" is given, nor is any proof adduced that the amount of tying and diagonal bracing required would fulfill his unknown definition.

The main point of the original criticism and discussion is the lack of mining-engineering talent on this construction work, which involves distinctly mining problems. The complete misconception of the causes of the "rock slides," variously attributed to "soft pockets," "unknown seams," "rotten rock" and other mysterious causes, would not have been had by mining engineers, who would have recognized immediately that the "rust seams" were common, ordinary joint and cleavage planes, and they would have known that the ground would break blocky and would have to be supported or it would slab off in huge blocks and slabs.

"The best practice in subway timbering, therefore, includes cross or transverse members to distribute load, to brace the sides of the excavation and to more securely tie the structure together." Inasmuch as the timbering in question did not "brace the sides of the excavation," which caved in and caused the fatal disaster, I submit that the practice was not proper, even though it is considered "the best practice in subway timbering."

New York City, Oct. 13. PERCY E. BARBOUR.

New Almaden Quicksilver Mine

In the *Journal* of Sept. 18 there appears an article entitled "New Almaden Quicksilver Mine," by Richard G. Place. There are some grave errors in this article.

In the third paragraph Mr. Place states that the ore is introduced into retorts. The New Almaden mines have not used retorts since some time in the '70s, and the present furnaces, which have been in use for several years, are of the latest type of 50-ton Scott tile furnace for the fines and of shaft furnace for the coarse rock. We do not know of any leakage of fumes from our condensers or furnaces that can be prevented in any way or that is of measurable quantity.

In the fourth paragraph he mentions "washing sand and dirt taken from under old parts of the workings that are being remodeled." This is correct if the reader understands that this dirt and sand is taken from the vicinity of abandoned flues and old furnace sites.

In making the foregoing comment, I merely wish to indicate to your readers (and our place is always open to inspection) that our present practice is not out-of-date nor unduly wasteful, although all quicksilver metallurgy is susceptible of great improvement.

W. H. LANDERS,
Chief Engineer, the New Almaden Co.

New Almaden, Calif., Sept. 27, 1915.

Brokers and Wildcats

But why go to the trouble to uproot the fake mining stocks, as Mr. Prill suggests in the *Journal* of Oct. 16? This only gives the "investor" the trouble of looking up something else as bad. Why give him unnecessary work?

New York City, Oct. 18, 1915. A. A. N.

More Mexican Mining Law

At present Mexico seems to be bothered with many different kinds of mining laws. The various so-called authorities no sooner promulgate one of them than something wrong is found with it and another is produced to modify or replace it. Because of the recent action of the United States in recognizing the Carranza faction, the laws devised and enforced by it demand more attention than any of the others. A study of the latest laws framed by Carranza leads to the suspicion that they may, and probably will, do a great deal of damage to the mining industry in Mexico. In that connection it will be of interest to study the law of Mar. 1, 1915, and its modification under date of Aug. 31, 1915, which are herewith presented.

MINING LAW OF MAR. 1, 1915

Modification and additions to the law.

The First Chief of the Constitutionalist army, in charge of the Executive Government, has been pleased to send me the following decree:

I, Venustiano Carranza, First Chief of the Constitutionalist army, in charge of the Executive Government of the Nation and Chief of the Revolution, exercising the extraordinary faculties with which I am invested, have considered it proper to decree as follows:

Art. 1. Articles 2, 5, 9 and 10 of the law of Mar. 25, 1915, regulating the stamp tax and the tax on mining franchises are modified and added to, as follows:

Art. 2. There are subject to the internal stamp tax, without any other exceptions than those expressly fixed in this law, the metals which have been produced in this Republic or which come from a foreign country. Said tax will be in future as follows:

a. On metals which are exported in the shape of ore or mineral or earth, cyanide or sulphide, furnace residue or in any other form and which are combined or mixed with substances which properly speaking are not metal, as follows:

Gold at the rate of $110 per kilogram.
Silver at the rate of $2.60 per kilogram.
Copper at the rate of $0.035 per kilogram.
Lead at the rate of $0.06 per each ten kilograms.
Zinc at the rate of $0.05 per each ten kilograms.

b. For the metals which are worked in the country, so that they do not remain mixed or alloyed except with other metals, and whatever be the assay of the product, there will be a reduction of 20% from the taxes fixed in the foregoing clause.

Art. 5. There is no tax on . . . . etc.

c. The taxes on copper will not be levied when the ore contains the metal mentioned in less amount than 10%, nor on lead when the ore contains a smaller amount than 10%, nor on zinc when the ore contains a smaller proportion than 15%.

Art. 9. The tax of special stamps which, according to the laws now in force, have to be adhered to the titles of ownership of the mines, will be $10 for each unit of mining field (pertenencia) covered by these titles, whatever be the mineral substance which it is intended to produce.

Art. 10. The annual tax on mine ownership will be as follows:

a. The rate will be $12 yearly per unit of mining field (pertenencia) or $4 for every one-third of a year, whatever be the material being mined.

b. If the number of pertenencias of a mining property, or of diverse properties belonging to the same owner and located in the same mining district, exceeds ten pertenencias, the tax will be at the rate of $12 for the first ten pertenencias, and for the excess up to twenty at the rate of $15. For the excess from twenty up to fifty the rate will be $18, and from fifty-one up the rate will be $24.

Transitory.

Art. 1. This decree commences to be in force this present day.

Art. 2. To the mining fields that have payments of taxes pending and have not yet been declared void, a time will be conceded up to June 30, 1915, to pay their debts in gold, in accord with the foregoing rates of this decree.

Therefore I order this to be printed, published, circulated and given due compliance.

Constitution and Reforms. Given in Veracruz, Mar. 1, 1915. Signed V. Carranza. To the Secretary of Finance and Public Credit. Present.

Which I communicate to you for your knowledge. Constitution and Reform. Veracruz, Mar. 1, 1915. The Secretary of Finance and Public Credit, Luis Cabrera.

Art. 2. Article 3 of the law referred to of Mar. 25, 1915, is void.

Art. 3. All amounts which the Public Treasury has to receive in accord with the present decree and with the law above mentioned of Mar. 25, 1915, shall be paid in national gold money.

CHANGES IN THE TAX ON MINING PROPERTY[1]

Decree of Aug. 31, 1915

The First Chief of the Constitutionalist Army, in charge of the Executive Government, has been pleased to send me the following decree:

I, Venustiano Carranza, First Chief of the Constitutionalist Army, in charge of the Executive Government of the Nation and Chief of the Revolution, exercising the extraordinary faculties with which I am invested, and

Considering that the mining business in general, on account of the social disturbance of the country, has been obliged to stop operations, especially points which were subject to the misconduct of forces which are hostile to the Constitutionalist Government and on account of scarcity of material of first necessity, which could not be acquired on account of the European war, have thought it well to decree, as follows:

Art. 1. For the periods of time hereafter mentioned, the accounts described in Art. 10 of the law of Mar. 25, 1915, which modifies Art. 1 of the decree of Mar. 1, 1915, regarding mining taxes, are reformed as follows:

a. The amount will be $6 yearly for each mining pertenencia, whatever be the number of pertenencias, during the four months covered by the months from July to November of the present year.

b. The amount will be $8 yearly for each mining pertenencia whatever be the number of the pertenencias, during the four months from November of this year to February, 1916.

c. From Mar. 1, 1916, the amounts will be those established by the decree of Mar. 1, 1915.

Art. 2. For the mining fields (pertenencias) for which payment of taxes prior to last July is pending, it is conceded that they pay $6 yearly, for each of the first 25 pertenencias and for the excess, $3.

Art. 3. To all the owners of mining property who have paid for the four months which commenced with last July, the excess will be returned, deducting what they have to pay according to this present decree.

Art. 4. A period of time is allowed until Sept. 30, 1915, for payment, without extra charge, of the amounts fixed by the present decree.

Art. 5. The payments referred to in the present decree have to be made in national gold or its equivalent in silver, in accord with the decree of May 8, of the present year.

Be this printed, published and circulated and given due compliance. Given in Veracruz Aug. 31, 1915. (Signed) V. Carranza. To Cit. Rafael Nieto, Secretary to the Treasury. Which I communicate to you for your knowledge and subsequent effects. Constitution and Reforms. Veracruz, Aug. 31, 1915. In the absence of the Secretary, the Asst. Secretary in charge. R. NIETO.

As to Villa, his exploits do not seem to be attracting a great deal of attention at the present time. There are rumors of his death, and other rumors which point out that it was his brother that was killed. His most important move is suggested in a recent announcement that he has requested, or commanded, that the American Smelting and Refining Co. operate at once its Chihuahua smelter and the tributary mines, threatening, if this is not done, to seize and operate them himself. The company, it is said, will endeavor to operate the smeltery to alleviate the destitution of its laborers at Chihuahua, but operation depends almost entirely upon the possibility of getting supplies into the camp and the ability of the company to ship its product.

[1]From El Paso papers of Sept. 30, 1915.

Producing Potash in Utah

A recent press bulletin from the Department of the Interior, announcing the production of potash from alunite in Utah, is another example of the bureaucratic advertising that has become popular with publicity-seeking department heads at Washington. It is full of half-truths covered with a political glaze that might easily give the uninformed public the impression that the Department of Interior or the Geological Survey was producing this potash. A layman reading this bulletin might gather that it was now demonstrated that the Utah alunite was to be regarded as a commercial source of potash in normal times of German competition, and the last paragraph conveys the impression that the potash deposits of Germany are alunite.

Why could not the Interior Department employ a competent Geological Survey expert and give him a free hand to tell the whole truth instead of these "half-truths" promoting "bureau publicity"? For the benefit of those who enjoy their politics and technics mixed, the Interior Department's press bulletin of Oct. 16, 1915, is reproduced herewith:

Secretary Lane today announced the production of the first commercial mineral potash in the United States. This came to him in the form of a report from a special agent of the Geological Survey, in Piute County, Utah, nearly in the central part of the state. The potash is found in a vein of a mineral known as alunite, which is the sulphate of alum-

inum and potassium. The vein found is about 10 ft. wide and has been traced for 3,500 ft. Its depth is not yet known. The alunite when removed is subjected to a very simple process of heating, dissolving in water, filtering and evaporating, and the potassium sulphate resulting is almost pure. About 200 tons of alunite has been put through the mill and two tons of 99% pure potash has been produced, and there is still in solution nearly 100,000 gal. containing large amounts of potash salts which has not yet been evaporated.

The discovery that this mineral yields potash in commercial quantities Secretary Lane regards as one of the most important discoveries made recently with reference to our natural resources, as it assures us of a domestic supply of potash for our national needs in the manufacture of explosives. Alunite is known to exist in the States of Colorado, Utah, Nevada, California and Arizona. It resembles in appearance disintegrated limestone. The technical description given by the Geological Survey of alunite is that it is a "fine-grained, compact rock, breaking with conchoidal fractures and having a porcelain-like appearance, but containing also considerable masses with a distinctly crystalline structure."

Heretofore the United States has been dependent upon the potash supply of Germany, where it is found in strata chiefly at a great depth. Our imports for 1913 of potassium salts were $15,000,000. The world has been dependent upon this German supply as an ingredient in modern fertilizer and in the manufacture of explosives. Potash is known to exist in the United States in some of the salt lakes of the interior, but has not been produced heretofore in any commercial quantity. Some potash has also been produced on the Pacific Coast from the kelp of the seacoast, which takes the potash from the salt water.

The Interior Department is also drilling at various points in the United States in search for potash deposits similar to those of Germany. Should alunite deposits of a similar character be found in large quantities in other states, its significance to the agriculture of this country can hardly be overestimated, as it is an essential soil food and will reestablish from year to year the draft made upon the potash in the soil by the crops produced.

Those who are familiar with the alunite development in Utah will interpret this bulletin as meaning that the private interests that investigated the Piute County deposits and have been constructing a reduction plant near Marysvale, have begun production on a small scale. Moreover, if two tons may be regarded as a commercial production, the feldspar-potash investigators have already taken the edge off the Department's "discovery."

Revision of Mining Laws

The Director of the Bureau of Mines has issued the following letter with respect to the convention that is to be held in Washington on Dec. 16, 1915, under the auspices of the Mining and Metallurgical Society of America, to urge upon Congress action toward a revision of the mining laws.

A convention that will act on recommendations regarding a general revision of the Federal mining laws will meet in Washington, D. C., on Dec. 16. All the known mining societies in the United States have been invited to send delegates, and it is hoped that the mining industry will be so well represented that the action of the convention will be regarded as expressing the wishes of the industry.

As the Bureau of Mines is necessarily interested in any movement intended to benefit mining through changes in Federal laws, I take the liberty of calling the convention to your notice and expressing the hope that, in case you cannot attend the convention, you will authorize someone to act for you.

Some of the resolutions that will come before the convention will recommend the fixing of a reasonable term of years beyond which placer claims shall be immune from attack on the ground of fraud, full privilege of appeal in all cases of contests over locations, recording of notices of mining locations so as to insure public notice, the abolishment of the law of the apex, and the appointment of a Government commission, under an act of Congress, to investigate and to make recommendations as a basis for the revision of the mining law.

In case you wish further details in regard to the convention, I shall be glad to supply you with such information as may be available.

VAN H. MANNING,
Director.

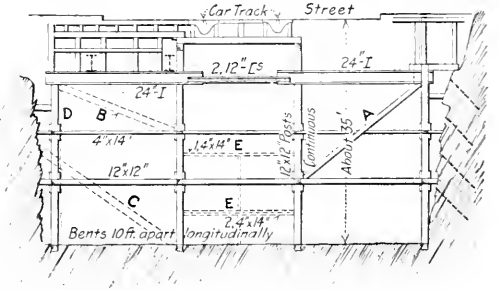
Washington, Sept. 24, 1915.

Ten thousand copies of this letter were distributed, these being sent to all mine operators in the public-land states and to all the more important mine operators in other states. Details respecting the convention will be published in due time in the several mining papers.

Comparative Timbering Costs in Mine and Subway

At the Goldfield Consolidated mine in Nevada during the year 1914, according to the company's annual report, there were mined 300,993 tons of ore. In estimating ore reserves of this mine 13½ cu.ft. of rock in place are estimated at one ton; therefore the tonnage mined in 1914 is equivalent to 150,497 cu.yd. of dirt. The total expense for mining this ore was $1,026,808.

The specifications for the section of the Broadway subway (Section 2, Routes 4 and 36), where the cave-in occurred on Sept. 25, called for a total excavation of 278,900 cu.yd. The contractors' bids ranged all the way from two million and a half to four million odd dollars.



SKETCH OF TIMBERING, BROADWAY SUBWAY, SOUTH OF 38TH ST.

The itemized bid of the successful bidder puts the cost per cu.yd. of excavation at $4.75. The total cost of the 278,900 yd. would therefore be $1,324,775.

This is so stated in order that both jobs can be compared on the basis of yardage removed, and the cost of the subsequent permanent subway construction does not enter in to complicate the illustration and cloud the issue. Here are two problems that are comparable in two important respects—the quantity of material moved and the money cost involved.

A most striking difference is noted in the amount of timber that these two problems used. Before taking this comparison further, it will be necessary to give a short explanation of the diagrammatic figure. For the sake of this comparison, only the timber below the 24-in. steel I-beams is to be considered, because we will assume, for the moment at least, that if a mining engineer had had charge of the timbering in the subway, he would have used just the same amount of timber in the decking, etc., above the 24-in. I-beam as the contractors used. The criticisms in the *Journal* of Oct. 2 were directed more particularly against the timbering below this 24-in. steel I-beam, which we will now consider.

A careful estimate of the amount of timber used in this bent, which any engineer can make from this sketch, shows that there is a maximum, after adding a liberal percentage for wastage in cutting, etc., of 4,500 ft. b.m. per bent. This section of the subway is 3,350 ft. long, and the bents are spaced 10 ft. apart. Estimating the cost of this timber at $50 per M, which is not only the figure used in various subway bids, but is also very close to the cost of timber in Nevada, the total estimated cost of the timber in this section of the subway timbering as per sketch would figure $75,600.

The Goldfield Consolidated report shows that for timber and lagging during the year 1914 there was expended $142,132, or nearly double the amount estimated for the subway excavation.

At the Goldfield Consolidated the greatest number of human lives to be considered in connection with the safety afforded by the timbering did not exceed 1,000. The number of human beings passing over the Broadway section of this subway during the construction period amounts to several hundred thousand per day.

There is, then, this striking comparison. The two problems of this particular mine and this particular section of the subway are comparable in both the yardage of dirt handled and the amount of money involved. In the case of the mine, although not nearly as many lives were to be safeguarded, although less dirt was moved and although the total cost of operation was less, practically double the amount was spent for timbering, which figured per cu.yd. excavated shows that the mining engineers spent in this case almost 3½ times as much for timbering as did the subway engineer.

	Subway Section 2, Routes 4 and 36	Goldfield Con. 1914 Operations
Excavating and mining costs.....	$1,324,775	$1,026,808
Cubic yards of dirt.....	278,900	150,497
Estimated cost of timber used.....	$75,600	
Actual cost of timber used.....	.....	$142,132
Cost of timber per cu.yd. excavated	$0.27	$0.94

Northeast Sonora Undisturbed

SPECIAL CORRESPONDENCE

Conditions in the Arispe-Moctezuma district of northeastern Sonora have been fairly quiet during the first week of October, the rumors of invasion by Villa's forces not having materialized. The Pilares mine of the Moctezuma Copper Co., near Nacozari, is at present producing 2,000 tons daily and the concentrator at Nacozari is running at full capacity. The Nacozari railroad had been nearly out of commission for three months, so that a great quantity of concentrates accumulated at the mill. By Sept. 18 these concentrates had been sent to the Copper Queen smeltery at Douglas and the usual one-train-per-day passenger service was resumed immediately. Although mine and mill are running full force, there had been up until a week ago considerable anxiety over the immediate future. What few American women had remained in the camps of Nacozari and Pilares left after President Wilson's request for all Americans to leave Mexico promptly, and the men remaining—practically the full staff—sent out their baggage, expecting that a hurry call might come at any time to close down and get out.

Villa's army was reported to be coming this way. This part of Sonora is Carranza territory, and after the reports of the battle between Calle's and Maytorena's troops came in, many of the Mexicans packed up and started for Agua Prieta. For several weeks everyone expected to receive notice to close down work in the Arispe-Moctezuma district and hurry to the States. But Villa's army did not seem to be getting nearer. Then reports of the refusal of Villa's troops to go until they were paid in gold came in, followed by others to the effect that his whole army was going to pieces. It hardly seemed credible that Villa would bring a large force into this part of Sonora, which is unproductive and where supplies are kept on hand only for immediate requirements.

The company stores are carrying small stocks, partly because not much has come in since the railroad resumed running and probably because it was deemed inadvisable to carry more than enough for immediate requirements. Certainly, even a small army would fare poorly in requisitioning all the merchandise in this district. There is an inclination now on the part of the men here to think that trouble in Mexico between contending factions must soon cease from exhaustion of supplies.

Some fear that Carranza's generals may not remain loyal and may start a movement to put themselves in power. As has been the case with all Mexican situations lately, the expected never happens, and while the history of the last few years would warrant such an anticipation, there are too many obstacles now, in the present condition of the country, to augur well for any ambitious general starting further trouble.

Reports from the daily press about the Yaquis and bandits do not correspond with the reports here. Of course, should Villa's army disband, it is to be expected that for a time the government—or whatever it is that takes the place of government—would be unable properly to police the great extent of territory, especially the less populated states such as Sonora, and for a time there probably would be depredations here and there by bands of outlaws. As for the Yaquis, the feeling between them and the Mexicans is reported still to be bitter, but there is no reason to suppose or to fear that American nonparticipants would be molested. The coveting of the Yaqui territory by the officials of a past government caused all the Yaqui troubles, and the tales of the cruel savagery of the Indians were doubtless manufactured for a purpose.

[A letter written a few days later supplementing this information appears under "Editorial Correspondence."—Editor.]

Ray Hercules Copper Co.

The Ray Hercules Copper Co. has been organized to acquire a large majority of the capital stock of the Arizona Hercules Copper Co., operating in the Ray district of Arizona. The orebody is said to be a continuation of the Ray Consolidated. The Ray Hercules has elected the following directors: August Heckscher, director of the New Jersey Zinc Co.; Ellis P. Earle, vice-president of the Granby Copper Co.; J. Guthrie Hopkins, director of the Arizona Copper Co.; George A. Huhn, banker, Philadelphia; W. F. Bartholomew, broker, Boston; Frank C. Armstrong, New York, president.

In Guatemala a recent presidential order provides that in the future the Guatemalan Government alone shall have the right to import telegraph and telephone apparatus. The right to import electrical material and supplies for the installation of such apparatus is likewise restricted to the Government, but their importation may be permitted if they are necessary for other installations.

Editorials

New Mining Taxes in Mexico

The revolution in Mexico has brought Carranza on the top of the wave, and his forces now hold most of the mining regions. Mining in Mexico, however, is mostly at a standstill. Only in a few places is it being prosecuted, and then on a much-reduced scale. Most of the American-owned mines have been closed. American citizens have been called out by orders from Washington. Other foreigners, if they have not been called out or ordered out, have generally been obliged to leave. This has entailed a lot of hardship and is costing a lot of money. The question now is, when and what chance will there be for successful resumption of operations when it is safe to return to work? The answer will depend greatly on the protection given to foreign mine operators by the party in power and on the taxes with which the industry will be burdened.

Taxes in general are being increased, and the mining industry will probably be made to carry a burden to its full capacity. The only limit will be what the camel's back can stand. On Mar. 1, 1915, Carranza issued a decree raising the mining taxes, and this decree was only temporarily modified by another, dated Apr. 1, 1915. The translation of the essential parts of these decrees is given elsewhere in this issue. They regulate the property tax (an internal-revenue tax depending on the size of the property) and the production tax (depending on the value of the ores and bullion produced). Large fields will have to pay virtually eight times as much property tax as they formerly paid. Not only does the tax affect the miner, but the work done by the miner affects the tax, and as he will have to be consulted sooner or later, it seems necessary for operators in Mexico to come to some general understanding in regard to these taxes.

The foreigner particularly is interested in the new mining taxes and regulations, since few of the older, larger or more important mines in Mexico are being held by Mexican owners. Mexican owners almost invariably hope to sell to the foreigner.

The purpose of the Carranza decree of Mar. 1, 1915, is evidently to break up large holdings and to stop speculation in undeveloped ground held with the expectation that it may become valuable by the exploration done on near-by property—as it is popularly expressed in words of the revolution, to keep the rich man from taking away the chances of the poor man who cannot afford to hold much ground, or to give the oppressed man a chance. At the present time any new measure that can be advertised as accomplishing this object is of course popular among the Carranza faction.

There is no doubt that abuses were committed under the old law, as there are under any law, but any permanent new decree will have two things to consider. The first of these is whether the new law be a successful revenue producer. Only time can tell this. At first the new law may be successful in an individual way, because many holders of mining ground, even if they want to reduce their holdings, will be obliged to take out new titles, which will require documentary stamps to the value of ten pesos, Mexican gold, for each unit or *hectara*, and also because miners and speculators may wish to take out titles for some of the ground abandoned by previous owners. Many of the middle-class people in Mexico were accustomed to invest their savings in mining property, not because they expected immediate returns, but because they considered the investment a safe one which might some day bring good returns—if not to them, to their children.

The second consideration is as to the effect the new tax on mining property will have on the industry. Will it increase or decrease the receipts from the tax on production—a source of income of much greater importance than the property tax?

There seems to be prevalent an idea that mining in general does not require large tracts of land. This may be true of special cases, but not of gold and silver mining in Mexico. Most of the value of the richer metals mined in Mexico is produced by the large operators. Their extensive operations, needing expensive plants, can be carried on only if there is a certainty that production will be permanent, and for this the first requisite is an ample field.

Formerly, when native labor was cheap and good, operations were carried on in Mexico by individuals. As the price of labor rose, mining operations had to be done on a larger scale with improved plants. Thus a larger investment was required, and to make such investments commercially safe large fields are necessary—not for speculative purposes, but simply to safeguard the investment. There are mining districts where ores are found in large bodies, but in most parts of Mexico silver and gold ores are not found this way. The ores usually occur irregularly in veins, in zones, in chimneys or in spots. To make continuous production possible in this class of mining, a large field is an absolute necessity. Work in small fields is necessarily done on what there is immediately in sight and is speculative. It is not to be trusted as a permanent business and therefore offers no attractions to foreign capital. For a while this kind of work may suit the local *gambucino*, who gouges out the ore in sight but does no development work, but it will not bring foreign capital into the country.

Another thing has to be taken into consideration: Every large mine operator in Mexico necessarily has to hold a quantity of unproductive ground—partly because it is impossible to say beforehand where the ore will be found and partly because profitable results cannot be obtained from large investments unless the adjoining ground is owned and controlled for present and future operations. Cut down the fields and you cut down exploration work.

The large mining establishments of Mexico have been built up on the faith in Mexico's good and clear mining laws. Many a mining district that was prosperous and promising a few years ago will be permanently crippled

if the industry is carelessly overtaxed now. Forcing property not now worked to be abandoned, with the idea that other owners will be found, does not necessarily promote mining or the production of ores.

A mining tax on the value produced sounds innocent, since nothing has to be paid when there is no production; but as there can be no mining industry without production, it is at best a heavier burden than any other industry has to bear and becomes unjust and iniquitous when it is abused. A few years ago a Mexican financier was asked how he excused this production tax on mining, and he replied that all store-keepers, farmers and many other industries had to pay a similar tax. This statement is not true. Stores turn over their capital only once or twice a year, while the miner has to put his working capital back in the ground weekly, or as soon as he realizes on his output. Furthermore, the storekeeper and the manufacturer charge their expenses to the goods and raise their sales prices accordingly. The miner has no say in the market quotation of his product.

To show what the tax on production actually means, let us take an example: Suppose we are practical miners and, like many others, are trying to make a living in Mexico out of a property bought in good faith under the Mexican laws. We bring a small working capital and start work under favorable conditions, investing our money in the weekly payrolls, in dynamite, fuse and other mining materials. To be able to keep on working it is primarily necessary that we net from the sale of the ores taken out the full amount of our weekly investment. The assay value of the gold and silver in the ore must of course be much higher, so as to be able to pay for freight, treatment and realization charges. Unless the ores are exceptionally rich the net cash value of the ore at the mine will be less than two-thirds of the assay value. According to the Carranza decree of Aug. 31, 1915, we have to pay taxes on the ores taken out, according to their assay value, as shown in the table.

TAX RATES UNDER THE NEW MEXICAN MINING LAW

Federal taxes: On gold at the rate of 8.27%, on silver at the rate of 8.09%, or, say	8.18%
State tax: This was formerly 1.50%, and, with an additional Federal charge of 20%, 0.30%	1.80%
	9.98%

Even if the state taxes are not raised, the government assay charges, document stamps, etc., increase this production tax to considerably more than 10% of the assay value of the ore, or to more than 15% of our net return, which again necessarily must be more than our working capital if we are to keep on working. We pay this on every week's product; therefore we pay this 15% fifty-two times a year, which makes more than 780% of our operating working capital.

Seeing that for some time to come the business of silver mining will have its difficulties, this amount of tax on production would certainly make us think twice before investing our little capital in Mexico.

The heavy mining taxes in Mexico have driven Mexican capital out of the business. The Mexican mine owner long ago found out that it was more profitable for him to sell his mine to the foreigner and to invest the money in some manner to exploit the miner instead of the mine. At the present moment the mining industry in Mexico is quiescent. To make it active, investment of money will be required. This money will have to be brought from foreign parts, but the careful foreign operator—the only one who can reëstablish the business—is not likely to invest in new enterprises when there is imminent danger that taxes will make profits impossible and property valueless. Now, before the decrees are ratified, it is up to the interested operators in Mexico to show the government what the results of heavy taxation are likely to be, and in order to get attention and consideration cooperative action will be necessary. How to bring this about, the operators will have to decide as soon as possible.

The Recognition of Carranza

At last the United States has recognized Carranza and Mexico has now, at least nominally, a legal government. As a preliminary to the new move Americans were once more warned to leave Mexico, and judging from the communications that have reached us, the women and children were generally sent out. The men appear, on the other hand, to have remained in order to look out for the property in their charge. This is brave, and American, and just what was to be expected, even if it be not wise.

Villa has breathed defiance and uttered threats, the latter being directed especially against the American Smelting and Refining Co., but so far has not done anything outrageous that has been reported. Carranza's first job will be to snuff out Villa. Then he will have to give attention to Zapata, who still prevails in his private palatinate. All of this may be done if Carranza's chieftains remain loyal. At present the great question is whether they are loyal, patriotic and intelligent, or whether some one of them thinks he holds a hand that he can play for his own account. But while waiting for time to answer this question, let us be glad that there is a possibility that order may be restored in Mexico.

The Clifton-Morenci Strike

Negotiations among certain distinguished "fugitives from justice," alias the Clifton-Morenci mine managers, the governor of Arizona, and representatives of the striking miners, have been going on at El Paso, Tex. The governor and the miners' representatives were almost pitiful in their beseeching of the "fugitives" to come back into Arizona and start their mines again, but the managers were wise and wary, having freshly in mind their recent experiences.

Moyer and his walking delegates apparently do not think much of mines without managers, and their followers have no high opinion of mines that have no payrolls. We wish it might befall Mr. Moyer to find a good mine and become a capitalist, for it would be interesting to see if his point of view would change as did that of the discoverers of the Hercules mine in the Cœur d'Alene.

In the meanwhile the attitude of the governor of Arizona and the state and county officers has been such that the mine managers were wholly justified in refusing to consent to return to that state for any palavering. The disgrace of the situation falls not upon them, but upon the state that could not or would not afford them the protection to which they were entitled. Arizona is run to a large extent by the taxes paid by its copper mining companies, which deserve more consideration than lately they have had.

BY THE WAY

Seventeen German ore steamers which ply in the Baltic Sea are missing, according to a Stockholm dispatch to the Exchange Telegraph Co., and are believed to have been sunk by British submarines.

⁂

Recent reports from Mexico of General Villa's death again appear to be slightly premature. If he has a spark of Mark Twain's genius, he will repeat the latter's famous telegram: "Reports of my death greatly exaggerated."

⁂

Closely guarding 1½ oz. of gold which she is taking to President Wilson for use in the wedding ring for his bride, Miss Dorothy Starr, daughter of the Empire Gold Mine's general manager, was on her way to Washington today, says an Oct. 18 dispatch from Grass Valley, Calif. She will also invite the President to pass part of his honeymoon in California.

⁂

Iron coins are to be used in Germany in place of nickel and copper. According to a recent ordinance of the Bundesrat, the Imperial Chancellor is empowered to authorize the coining of 5-pfennig pieces out of iron to the value of 5,000,000 marks. These coins are to have a milled edge and will contain the words "Deutsches Reich" over the figure "5" and the word "pfennig" under it, followed by the date. The obverse will have the usual stamp of the Imperial coat of arms. The new coins are to replace those now made of nickel and copper, and they are to be withdrawn from circulation not later than two years after the conclusion of the present war.

⁂

The following story is from the American Smelting and Refining Co.'s safety-first bulletin. John Eggen, a structural iron worker at the Garfield plant, was fastening corrugated iron on the roof of the coal-pulverizing plant, when an explosion of powdered coal occurred in the elevator directly under him. He was blown about 10 ft. in the air, lighting on the roof again. He received slight bruises about the face and wrenched his back, and two front teeth were loosened. He was disabled for 5½ days. However, John was thoughtful and to his foresight owes his life. Before he attempted this work on the roof, he fastened a rope around his leg, with the other end of the rope firmly tied to the roof. This safety line prevented his being blown off the roof.

⁂

To a district of "crosscut tunnels driven to intersect the vein at great depth" came a young graduate of a short-cut mail-order mining school, after two months' experience as timekeeper at a New England quarry. Being the nephew of the treasurer of the Cheerful Hopes Mining, Milling and Smelting Co., Consolidated, it was quite fitting that he should be appointed general manager of the company's sole assets, which consisted of 450 ft. of tunnel in barren quartzite. The youth, erroneously dubbed as "one of these here Eastern college dudes," rented a suite of offices in the First National Bank Building of the railroad town and proceeded in a serious way to earn a portion of the liberal salary bestowed upon him by engaging a big Swede foreman and one ordinary miner to furnish copy for the company's press agent by renewed activity at the main tunnel. Supplies were bought and shipped to the property with all due formality, Ole being requested to sign in triplicate a printed voucher form. He did so, and in the space for remarks he laboriously penciled, "Why in Hell you send me only 6 candles?" Upon receipt of this communication the haughty official bit his lip and remarked, "The dirty grafter. Why, I only hired those men to work day-shift."

⁂

The reputation of Henry Ford as an automobile builder and industrial innovator ought to protect him from the wonderful "discoveries" attributed to him by would-be friends in the newspapers. The latest is contained in a dispatch from Detroit to the New York *Times*, which says that "hereafter the iron ore consumed at the Ford plant will go into the blast furnaces in its crude state and be refined by one 'heat' into both pure gray iron and malleable iron. From the time the crude ore enters the furnace until it is turned out in the form of complete parts for motor cars it will not be allowed to cool." As the world has been making iron from ore "in one heat" and running into molds direct from the blast furnace for uncounted years, the new "discovery" will not upset the iron industry to any great extent.

⁂

The great mines of the Eureka district, the Richmond and Eureka Consolidated, long ago vanished from the list of stock quotations, leaving behind them the walls of their smelteries and two immense slag dumps, one at each end of Main St. These unsightly piles add no beauty to the landscape, writes Charles E. Van Loan in describing Nevada's "Ghost Cities" in the *Saturday Evening Post*, but Eureka is convinced that the slag in one of those piles will yield a handsome fortune if ever resmelted. Main Street sentried at both ends by the bare bones of smelteries and refineries, idle these 25 years, is no longer the scene of gun fights, of bowie-knife duels, of Fourth of July parades, with the "Hooks" and "Knicks" proudly kicking up the dust behind the Union Guard Brass Band. Main Street, Eureka, is a very wide street, as Nevada streets go; but a shortsighted hen is perfectly safe on it these days, unless it be her misfortune to pick out the spot where the baseball team is practicing. There was a time—and not so long ago, either—when Main Street was no place for a hen. And speaking of that baseball club, it has to travel 80 miles to get a game. Eureka once had some lively daily newspapers and at least one journalist who achieved national fame; but now she is content with a weekly, which is well edited but somewhat lacking in local news items as compared with the boom period. There are no gamblers in Eureka today, but the inhabitants are past masters at solo, and take money away from the Duckwater farmers, who only think they know that interesting game. The 20-mule teams and towering ore wagons, once the pride of eastern Nevada, have given place to a narrow-gage railroad which meanders leisurely northward through the sagebrush, 80 miles to Palisade, where it taps—ever so gently—one of the main arteries of transcontinental traffic. Ordinarily a railroad is a better and cheaper method of transportation than a mule team, but the "Slim Princess" does not haul any ore these days. The mining companies and the "Slim Princess" have been at a deadlock for years, and until that deadlock is broke, the ore will remain in the mines.

The Bethelehem-Pennsylvania Steel Combination

The arrangements for transferring the control of the Pennsylvania Steel Co. were completed at conferences held in Philadelphia, Oct. 15 and 16. The agreement involved the transfer to Charles M. Schwab and associates—who control the Bethlehem Steel Co.—of the Pennsylvania Steel Co. stock heretofore held by the Pennsylvania Railroad Co. This was a majority of the stock and to it was added that owned by the Reading Iron Co., which is a Philadelphia & Reading subsidiary. Outside stock will also be taken by the purchasers. While the details of the transaction have not been made public, it is understood that the stock passes at $100 per share for the preferred and $35 per share for the common, and the transaction involves the payment of between $49,000,000 and $50,000,000 in cash or securities.

The Pennsylvania Steel Co. is one of the larger independents outside of the Steel Corporation. It has a blast-furnace capacity of nearly 2,500,000 tons yearly, and extensive steel works, the most important being at Steelton, Penn., near Harrisburg. Moreover, it owns the Maryland Steel Co., with blast furnaces and steel works at Sparrow's Point, near Baltimore, with which is combined a large shipbuilding plant. A very valuable asset also is its ownership of great deposits of iron in Cuba, which include large developed mines and working transportation lines for delivery of ore at Baltimore and Philadelphia.

The Bethlehem Steel Co. has been for some time accumulating iron-ore reserves. Some years ago it made a long contract for Swedish ore and recently bought an extensive iron field at Tofo in Chile. Its investments in Texas iron lands have not, it is understood, turned out very well. The Cuba iron ores will be a valuable addition to its resources.

It is stated that there will be no consolidation, the Pennsylvania Steel Co. continuing to operate under its own organization.

It is reported that negotiations are in progress for the control of J. G. Brill & Co., a corporation operating several large car shops in Philadelphia and the West.

There were reports that the Cambria Steel Co. would also be joined in this consolidation, but they have been denied. The control of the Cambria, it seems probable, will pass to a syndicate headed by W. H. Donner, who holds an option on the stock in the company held by the Pennsylvania Railroad Co., and on other stock. A reported sale of the Thomas Iron Co., the oldest and largest merchant pig-iron maker in the East, is also denied.

*

Ore Tonnage and Valuation on Minnesota Iron Ranges

BRAINERD CORRESPONDENCE

The assessed valuation of the unmined ore in St. Louis, Itasca, Lake and Crow Wing counties is placed at $268,084,988 by the state tax commission. This includes the four Minnesota ranges. The tonnage is figured at 1,481,919,571. Iron ore, mined or unmined, is assessed at 50% of its true value as provided by law, while all other state property is assessed at from 25 to 40% of its true value. The new valuation will bring $1,112,552 into the state treasury next year. The rate fixed by the auditor is 4.15 mills. In 1906 the assessed valuation of the mineral lands was but $64,486,409. In 1907 the state commission was organized and the valuation was placed at $191,706,682. Last year it was $259,987,396. The remaining tonnage in the ground in the four counties is figured as follows: St. Louis, 1,232,058,631; Itasca, 160,795,969; Lake, 115,115; Crow Wing, 88,949,856.

*

Tennessee Copper Will Extend Its Acid Plant

At a special meeting of the Tennessee Copper Co., held in New York on Oct. 18, the stockholders approved the proposed issue of $3,000,000 first-mortgage 10-year convertible 6% bonds, of which $2,000,000 are to be issued at present. The bonds are convertible after two years at the rate of $160 in bonds for $100 par value in stock. An increase in the company's capital stock to $6,875,000 was also authorized to provide for the conversion of the bonds. After applying $800,000 of the present funds to the retirement of old bonds, the balance will be used for plant extensions made necessary by the great demand for sulphuric acid.

President Utley Wedge stated that while no figures could be given at present as to the extent of the plant enlargements, the annual capacity would be materially increased. For several years there has been evidence of a greater market for sulphuric acid in this country, entirely aside from present extraordinary demand. The output of the old plant of the Tennessee Copper Co. has been considerably augmented and the additional capacity of about 25,000 tons—contemplated about a year ago, but held in abeyance by financial conditions—is now being completed and will probably be in commission within 30 days. This year the company will produce about 225,000 tons of acid. Copper costs at present are excellent, and it is expected that the company's yearly statement will show a considerable reduction in cost over previous years.

*

Graphite Production in 1914

The United States produced 1,725 tons of amorphous graphite and 2,610 tons of crystalline graphite in 1914, and imported 22,002 tons, of which 8,374 came from Ceylon, 6,327 from Chosen, 4,259 from Mexico, 1,806 from Canada and 1,236 from seven other countries. Seven firms produced graphite in the United States, according to the Geological Survey—three in Alabama, one in Montana, two in New York and one in Pennsylvania.

Prices paid in New York during 1914 were approximately as follows:

Ordinary Lump	C. per Lb.	Dust	C. per Lb.
Best	8½-10½	Best	4 - 5½
Medium	7 - 9	Medium	3 - 4
Poor	6 - 8	Poor	2 - 3
Chip		Flying Dust	
Best	7 - 9	Best	2½- 3½
Medium	6 - 8	Medium	2 - 3
Poor	4 - 7	Poor	1½- 2

Madagascar graphite sold at $100 to $150 per ton, c.i.f., in New York. This is mostly of the flake variety. The crude Chosen amorphous graphite sold at $22.50 to $25, while refined Mexican amorphous graphite of leadpencil grade sold at 4 to 8c. per lb. Huff electrostatic installations are used by two of the Alabama companies for final cleaning.

NEW PATENTS

United States patent specifications listed below may be obtained from "The Engineering and Mining Journal" at 25c. each. British patents are supplied at 40c, each.

AGGLOMERATES—Process for the Manufacture of Agglomerates. Alphonse Exbrayat, Paris, France. (U. S. No. 1,154,980; Sept. 28, 1915.)

AGITATOR for Ore Treatment. Cyrus Robinson, Mount Vernon, N. Y., assignor to Metallurgical Engineering and Process Corporation. (U. S. No. 1,156,372; Oct. 12, 1915.)

ALKALI METALS—Improvements in and Relating to the Electrolytic Production of Alkali Metals. Badische Anilin and Soda Fabrik, Ludwigshafen-on-Rhine, Germany. (Brit. No. 17,763 of 1914.)

ALUMINUM COMPOUNDS—Volatile Aluminum Compounds and Process of Producing Same. Samuel Peacock, Philadelphia, Penn., assignor, by mesne assignments, to Agricultural Research Corporation, New York, N. Y. (U. S. No. 1,154,801. Sept. 28, 1915.)

BELT IDLER. Walter J. Armstrong, Columbus, Ohio, assignor to Jeffrey Manufacturing Co., Columbus, Ohio. (U. S. No. 1,156,336; Oct. 12, 1915.)

BLASTING CARTRIDGE. Paul Heylandt, Berlin, Germany, assignor to Firm Maschinen- und Apparate-Fabrik A. R. Ahrendt & Co., Berlin, Germany. (U. S. No. 1,154,770; Sept. 28, 1915.)

BRIQUETTING Ore Concentrates. Charles E. Hermann, Searsdale, N. Y., assignor to Moose Mountain, Ltd., Sellwood, Ont., Canada. (U. S. No. 1,155,311; Sept. 28, 1915).

CEMENT—Improved Method of Burning Cement, Ores and the Like Materials. Firm G. Polusius, Dessau, Germany. (Brit. No. 17,145 of 1914.)

CLASSIFIER—Ore Classifier. David J. Nevill, Denver, Colo., assignor to Dorr Cyanide Machinery Co., Denver, Colo. (U. S. Pat. Nos. 1,156,543 and 1,156,544; Oct. 12, 1915.)

COMPRESSORS—Governor for Air Compressors. Charles Otis Palmer, Cleveland, Ohio. (U. S. No. 1,154,798; Sept. 28, 1915.)

CONVEYOR. Freeman R. Willson, Jr., Columbus, Ohio, assignor to Jeffrey Manufacturing Co. (U. S. No. 1,156,385; Oct. 12, 1915.)

CRUSHER MANTLE. George F. De Wein, Milwaukee, Wis., assignor to Allis-Chalmers Manufacturing Co., Milwaukee, Wis. (U. S. No. 1,154,100; Sept. 21, 1915.)

CYANIDES—Process of Making Cyanides. Arthur C. Spencer and Karl P. McElroy, Washington, D. C. (U. S. No. 1,156,108; Oct. 12, 1915.)

CYANIDING—Process of Extracting Metals from Ores. Robert S. Towne, New York, and Cyrus Robinson, Mount Vernon, N. Y., assignors to Metallurgical Engineering and Process Corporation. (U. S. 1,156,382; Oct. 12, 1915.)

DRILL. Walter Roy Hockabout, Palo Alto, Calif. (U. S. No. 1,154,636; Sept. 28, 1915.)

DRILL—Percussion Drill. Charles L. Lawton, Hancock, Mich. (U. S. No. 1,154,642; Sept. 28, 1915.)

DRILL HOLDER. Harry C. Lawson, McGregor, Tex. (U. S. No. 1,156,079; Oct. 12, 1915.)

DRILLING—Rock-Reamer for Drill-Heads. John P. Karns, Boulder, Colo., assignor to J. P. Karns Tunneling Machine Co., Boulder, Colo. (U. S. No. 1,156,147; Oct. 12, 1915.)

DRILLS—Adjusting Device for Rock Drills. Aberham L. Bolson, Mason, Nev. (U. S. No. 1,155,034; Sept. 28, 1915.)

DRILLS—Improvements Connected with the Process or Method of Reducing Metals from Their Ores or Other Metal-Bearing Material. E. Millinton, Barrowash, Derbyshire, and Kittel Co., London, Eng. (Brit. No. 20,832 of 1914.)

DRILLS—Improvements in or Connected with Rock Drills. A. Robertson, and J. Jackson, Bolton, Eng. (Brit. No. 19,299 of 1914.)

DRILLS—Shackle for Drills, Etc. Mather W. Sherwood, Franklin, Penn., assignor to Chicago Pneumatic Tool Co., Chicago, Ill. (U. S. No. 1,154,941; Sept. 28, 1915.)

ELECTRIC FURNACE. Edgar F. Collins, Schenectady, N. Y., assignor to General Electric Co. (U. S. No. 1,156,668; Oct. 12, 1915.)

ELECTRIC FURNACES—Apparatus for Improving the Stability of Furnaces with Magnetically Extended Electric Arcs. Einar Trove, Christiania, Norway, assignor to Norsk Hydro-Elektrisk Kvaelstofaktieselskab, Christiania, Norway. (U. S. No. 1,156,292; Oct. 12, 1915.)

EXCAVATING APPARATUS. Cyrus R. West, Dawson, Yukon Territory. (U. S. No. 1,154,357; Sept. 21, 1915.)

EXCAVATOR—Disintegrator Attachment for Elevator Buckets. Charles C. Jacobs, Amboy, Ill., assignor to Frederick C. Austin, Chicago, Ill. (U. S. No. 1,156,291; Oct. 12, 1915.)

FLOTATION—Apparatus for Ore Concentration. Arthur Howard Higgins, London, England, assignor to Minerals Separation American Syndicate (1913) Ltd., London, England. (U. S. No. 1,155,816; Oct. 5, 1915.)

FLOTATION—Apparatus for Ore Concentration. Arthur Howard Higgins and William Warwick Stenning, London, England, assignors to Minerals Separation, Ltd., London, England. (U. S. No. 1,155,815; Oct. 5, 1915.)

FLOTATION—Apparatus for the Concentration of Ores. Thomas Mackellar Owen, Broken Hill, N. S. W., assignor to Minerals Separation American Syndicate (1913) Ltd., London, Eng. (U. S. No. 1,155,836; Oct. 5, 1915.)

FLOTATION—Ore Concentration. Louis Albert Wood, London, England, assignor to Minerals Separation American Syndicate (1913), Ltd., London, England. (U. S. No. 1,155,861; Oct. 5, 1915.)

FULLERS' EARTH—Process of Treating Fullers' Earth. Richard Claus, deceased, East Orange, N. J., by Ida Claus, executrix Montague township, Sussex County, N. J. (U. S. No. 1,155,466; Oct. 12, 1915.)

FURNACE STACKS—Stack-Head or Boot for Hot-Air Stacks. Albert G. Scherer, Chicago, Ill., assignor to the Excelsior Steel Furnace Co., Chicago, Ill. (U. S. No. 1,155,761; Oct. 5, 1915.)

GALVANIZING FURNACE. Charles Fell, Elyria, Ohio, assignor to National Tube Co., Pittsburgh, Penn. (U. S. No. 1,156,353, Oct. 12, 1915.)

GASES—Apparatus for Cooling and Purifying Furnace Gases. Ernst Hofmann, Duisburg, Meiderich, Germany. (U. S. No. 1,155,237; Sept. 28, 1915.)

HOISTING—Brake for Use on Hoisting Devices. Hermann Graumüller, Berlin, Germany. (U. S. No. 1,154,508; Sept. 21 1915.)

IRON AND STEEL—Method of Changing the Composition of Iron and Steel. Bruce Ford, Philadelphia, Penn. (U. S. No. 1,156,679; Oct. 12, 1915.)

KILN LINING—Basic Lining for Kilns. Spencer B. Newberry, Bayridge, Ohio, assignor to Sandusky Portland Cement Co., Cleveland, Ohio. (U. S. No. 1,156,918; Oct. 5, 1915.)

LAMPS—Apparatus for Electrically Igniting Miners' Safety Lamps. Victor Ernest Joyce, London, England. (U. S. No. 1,154,992; Sept. 28, 1915.)

LEAD—Process of and Apparatus for Comminuting Lead. Clifford D. Holley, Detroit, Mich., assignor to Acme White Lead and Color Works, Detroit, Mich. (U. S. No. 1,156,079; Oct. 12, 1915.)

MAGNESIA—Process of Obtaining Magnesia. Joseph A. Bradburn, Syracuse, N. Y. (U. S. No. 1,156,662; Oct. 12, 1915.)

METAL COATINGS—Method of Applying Protective Coatings to Metallic Articles. Clarence Mark, Evanston, and Clayton Mark, Jr., Lake Forest, Ill., assignors to Clayton Mark, Lake Forest, Ill. (U. S. No. 1,155,317; Sept. 28, 1915.)

METAL TREATMENT—Treatment of Metals to Render Them Inoxidizable. Tycho Van Aller, Schenectady, N. Y., assignor to General Electric Co. (U. S. No. 1,155,974; Oct. 5, 1915.)

MICA-SPLITTING MACHINE. Edward Cooper, Newton, Mass. (U. S. No. 1,155,298; Sept. 28, 1915.)

MINE-CAR BRAKE. Clyde E. Morgan, Holdenville, Okla. (U. S. No. 1,154,041; Sept. 21, 1915.)

MINE-CAR WHEEL. Wilbur D. Hockensmith, Penns Station, Penn., assignor to Hockensmith Wheel and Mine Car Co., Penns Station, Penn. (U. S. No. 1,154,960; Sept. 28, 1915.)

MINE-CAR WHEELS, Bushing for. Christ A. Specht, Punxsutawney, Penn., assignor of one-half to George L. Schicker, Punxsutawney, Penn. (U. S. No. 1,154,345; Sept. 21, 1915.)

MINE DOOR—Manually Operated Mine Door. Newton K. Bowman, North Lawrence, Ohio. (U. S. No. 1,155,703; Oct. 5, 1915.)

MINER'S SHOE. John T. Crowley, Beacon Falls, Conn., assignor to the Beacon Falls Rubber Shoe Co., Beacon Falls, Conn. (U. S. No. 1,155,644; Oct. 5, 1915.)

NITRIC ACID—Process of Concentrating Dilute Nitric Acid. Emil Collett, Christiania, Norway, assignor to Norsk Hydro-Elektrisk Kvaelstofaktieselskab, Christiania, Norway. (U. S. No. 1,154,289; Sept. 21, 1915).

NITRIDES—Process of Forming Double Nitrides. Samuel Peacock, Chicago, Ill., assignor by mesne assignments, to Agricultural Research Corporation, New York, N. Y. (U. S. No. 1,154,800; Sept. 28, 1915.)

NITROGEN—Process of Fixing Nitrogen. Ottokar Serpek, Paris, France, assignor to Société Générale des Nitrurés, Paris, France. (U. S. No. 1,155,840; Oct. 5, 1915.)

OIL BURNER. Jesse Ditson, Littleton, Colo., assignor to the J. Geo. Leyner Engineering Works Co., Littleton, Colo. (U. S. No. 1,151,101; Sept. 21, 1915.)

ORE REDUCTION—Ore-Disintegrating and Screening Machine. George Woodson Crowe, Santa Cruz, Calif. (U. S. No. 1,156,394; Oct. 12, 1915.)

ORE SEPARATOR. Edward Torrey, Thetford Mines, Que., Canada. (U. S. No. 1,155,292; Sept. 28, 1915.)

PNEUMATIC TOOL. Charles Otis Palmer, Cleveland, Ohio. (U. S. No. 1,154,797; Sept. 28, 1915.)

PNEUMATIC TOOLS—Compressed-Air System for Operating Pneumatic Tools. Charles Otis Palmer, Cleveland, Ohio. (U. S. Nos. 1,154,793, 1,154,794, and 1,154,795; Sept. 28, 1915.)

POTASSIUM CHLORIDE—Process of Obtaining Potassium Chloride. Joseph A. Bradburn, Syracuse, N. Y. (U. S. No. 1,156,388; Oct. 12, 1915.)

PRECIPITATION—Process of Precipitating and Separating Metals from Solution. Robert S. Towne, New York, and Cyrus Robinson, Mount Vernon, N. Y., assignors to Metallurgical Engineering and Process Corporation. (U. S. No. 1,156,383; Oct. 12, 1915.)

PULP—Mechanism for Feeding Pulps. William R. Macklind, Cleveland, Ohio, assignor to George A. Martin, trustee, Cleveland, Ohio. (U. S. No. 1,154,190; Sept. 21, 1915.)

PULVERIZED FUEL—Air-Feed for Pulverized Fuel. Simon Henry Harrison, Easton, Penn. (U. S. No. 1,155,725. Oct. 5, 1915.)

RADIUM—Production of Concentrated Radium Residues and the Separation of Radium Compounds Therefrom. Otto Paul Curt Bredt, New York, N. Y. (U. S. No. 1,154,230; Sept. 21, 1915.)

ROLLING MILL. Johann Puppe, Breslau, Germany. (U. S. No. 1,154,884; Sept. 28, 1915.)

SAMPLING APPARATUS. Alexander G. McGregor, Globe, Ariz. (U. S. No. 1,155,670; Oct. 5, 1915.)

SHOVEL-DIPPER DOORS, Tripping Device for. Frank H. Armstrong, Vulcan, Mich. (U. S. No. 1,154,157; Sept. 21, 1915.)

STADIA TRANSIT. Willie L. E. Keuffel, Hoboken, N. J., assignor to the Keuffel & Esser Co., Hoboken, N. J. (U. S. No. 1,154,253; Sept. 21, 1915.)

PERSONALS

P. C. Schraps, of the South American Development Co., has arrived in New York from Ecuador.

John Tyssowski, mining engineer, was married in Washington, Oct. 9, to Miss Catherine Woodward.

Homer L. Carr has been appointed instructor in mining in the Columbia School of Mines, New York.

Kirby Thomas was in Denver Oct. 12 on his way home to New York from several examinations in the West.

C. S. Herzig, of London, Eng., passed through Denver Oct. 7, after making investigations at Ouray and other points.

Bonthrone & Co., mining engineers, have removed from Bank of Hamilton Building, Vancouver, B. C., to 300 Pender Street West.

W. D. Burcham has left the employ of the Presidio Mining Co. to open up some mines in the Terlingua quicksilver district, Texas.

M. H. Rylatt, of Old Leak, Boston, Eng., has been inspecting his mining interests in the Ouray district and is now on his way home.

Col. Frederic Nicholls, of Toronto, has been appointed acting president of the Dominion Steel Corporation on account of the illness of President J. H. Plummer.

Harley E. Hooper has resigned his position with the Junction North Mine, Broken Hill, N. S. W., to join the staff of Radcliffe & Co., of Kanbauk Mines, Tavoy, Burma.

Frank H. Probert, of San Francisco, is looking over recent developments on the Comstock Lode. From Nevada he expects to go to the Bingham and Park City districts in Utah.

J. Menard, formerly business manager of the West Canadian Collieries, Blairmore, now serving with the Canadian forces in Europe, has been awarded the Distinguished Conduct Medal.

H. S. Lee will spend the next two or three months in the Northern Ontario district on examination work for the U. S. Smelting, Refining and Mining Co. His headquarters will be at Haileybury.

Professor H. O. Hofman, of the Massachusetts Institute of Technology, delivered a lecture before the Franklin Institute, Philadelphia, Oct. 20, on "Recent Progress in the Metallurgy of Copper."

Hon. Louis Coderre, Canadian Secretary of State and head of the Mines Department, has resigned to accept a judgeship and is succeeded by Hon. Pierre Blondin, recently Minister of Inland Revenue.

John Page, superintendent of the Illinois Lead and Zinc Co., Galena, Kan., started for Los Angeles, Calif., and other western points. In his absence Earl Ryan will look after the company's interests.

W. H. Stavert has been chosen president of the Lake Superior Corporation succeeding Thomas Gibson, who remains with the company as general counsel. James Hawson has been chosen a vice-president in place of W. F. Taylor.

Spruille Braden, of New York, a son of William Braden, of the Braden Copper Co., and Miss Maria Solar de Humeris, were married Sept. 15, in Santiago, Chile. Mr. Braden was graduated from Yale in the class of 1914, and the bride comes of an old Spanish family.

Col. D. C. Jackling, accompanied by a party of friends, arrived in Juneau, Alaska, early in October to inspect the Perseverance Mine, Thane Mill, Annex Creek power project, Kensington Mine and other properties. The party arrived on Jackling's yacht "Cyprus."

Barney S. Shearer has been appointed master mechanic at the White Pine Extension in Michigan. For many years Mr. Shearer was master mechanic at the Wolverine mine, later mill superintendent at Gay, in charge of both Mohawk and Wolverine stamp mills.

R. B. Watson, general manager of the Nipissing Mines Co., has returned to Cobalt from a trip of inspection with some of the directors to examine mining properties near Le Pas, Manitoba, and states that no decision as to purchasing will be arrived at until careful sampling has been made.

Several changes in the Carnegie Steel Co. have followed the recent change in the presidency. William Whigham recently assistant to the president of the company, on Oct. 7 was made vice-president and will serve with Col. H. P. Bope and W. W. Blackburn. The appointment was made in recognition of Mr. Whigham's valued services as an engineer. Edward J. Hamilton, who was assistant superintendent of the Duquesne works, is now general superintendent of that plant. His former position is held by Ambrose N. Diehl, who has been succeeded as superintendent of the blast-furnace plant at Duquesne by Harry M. Stewart, former assistant superintendent of the blast-furnace department.

OBITUARY

George H. Abeel died suddenly at Ironwood, Mich., Oct. 13. He was for a number of year connected with the Castile Mine on the Gogebic Range. He was a member of the Lake Superior Mining Institute from its start and in 1913-14 served as vice-president.

The body of T. F. Cheyney, mining engineer of Timmins, Ont., who had been missing since Aug. 30 and was last seen at the Dome Mines office, was found on Oct. 14 in the bush near Timmins Townsite. A revolver was found about 30 ft. from the body. No money was found on his clothes, though he was known to have had money with him. Appearances of a struggle were noted, and the police believe that he was murdered. Cheyney came from Cleveland, Ohio, some years ago and was well known in the mining camps of northern Ontario.

Joseph Sutcliffe, mining and oil operator, San Francisco, jumped or fell from a window on the sixth floor of the Lathrop Building on Oct. 1. He struck the sidewalk and was killed instantly. He had been suffering from paresis and was visiting the office of Dr. J. Henry Barbat. The physician not having the medicine for which Sutcliffe called, promised to visit him at his home that evening. Sutcliffe gave no evidence of his intention and appeared in pleasant humor. His wife, however, said that he has acted queerly before leaving home. He was 37 years old, son of W. W. Sutcliffe, and brother of William Sutcliffe of the German-American Bank of New Orleans. He was well known in the California oil fields and reputed to be wealthy.

Dennis Sullivan, whose death was briefly noted last week, died at Denver, Oct. 10, aged 76 years. He was conspicuous in the mining and banking circles of Colorado. He was a self-made man in the commonly accepted sense. He arrived in Gilpin County, in 1866, with his wife and a few dollars saved up as a conductor on the Harlem R.R. and began as a common miner. Within a few months he acquired an interest in the Roderick Dhu mine, in which a rich strike soon put him in a position to go still more deeply into mining. When Leadville's '79 excitement set in, Mr. Sullivan moved from Central City and quickly secured interests in new mines that produced well. He made money in the Little Chief, Castle View, Big Chief and Penn mines. He owned the Tam O'Shanter mine which he acquired after a costly litigation with the late H. A. W. Tabor. He moved to Denver in 1883, soon becoming president of the city's water-supply company. In 1884 he was one of the organizers of the Denver National Bank, the initial directors including, beside himself, James B. Grant, William H. James and H. H. Eddy, all of whose names are linked with the mining history of this state, especially in connection with the Omaha & Grant Smelting Co. Mr. Sullivan held an interest in El Potosi mine, Chihuahua, Mexico; owned the Brittania copper mine on Vancouver Island, B. C., and was a heavy stockholder in the Yak Tunnel Co. He had always been quietly active in state and local politics, influencing affairs in the Democratic party but never seeking or holding office. He was a delegate to the national convention that nominated Grover Cleveland for the presidency. In his death, the state has lost one of its most respected citizens as well as one of its most earnest captains of finance, mining and general industry.

SOCIETIES

Society of Chemical Industry—The regular meeting of the New York Section was to be held Oct. 22. The subject for the meeting was the Coal Tar and Aniline Industry in the United States; to be discussed from scientific and commercial points of view by E. E. Pratt, J. F. Schoellkopf, Thomas H. Norton, J. M. Matthews and John P. Wood.

American Institute of Mining Engineers—The next meeting of the New York Section will be held Oct. 28, at the Machinery Club, 50 Church St. The meeting will be preceded by a dinner served at 6:30. Following the dinner the subject of "The Subways of New York City" will be discussed.

Editorial Correspondence

SAN FRANCISCO—Oct. 13

At the First-Aid Contests at the Panama-Pacific Exposition a wooden gallery was constructed in the north garden illustrating two divisions of a tunnel or drift connected by a stope, drift and raise. The structure was built low requiring the men to stoop. The parts representing the two divisions of the tunnel were open on the sides. The stope and raise were closed in with glass on one side for part of the length. This inclosure was supplied with formaldehyde and sulphur. The men were provided with breathing apparatus. They made some fine scores in the mine-rescue work. The first-aid events were demonstrated in the open and the demonstrations attracted the applause of the visitors generally and the hearty commendation of mining men.

Hydraulic Mining in Nevada and Placer Counties is being stimulated by efforts on the part of owners in the Lowell Hill, You Bet, Dutch Flat, Gold Run and other districts on Bear and American Rivers to secure Congressional appropriations amounting to $150,000 for building a restraining dam on Bear River. Petitions are being forwarded to Congressman Raker. A large number of hydraulic mines in this region have been idle since the law regulating this class of mining has been in operation. Many experiments have been made by owners in the construction of individual dams but never with great success. As in other regions in California, a number of hydraulic mines in this region could be operated individually by having a common point for disposal of the tailings. These mines are probably capable of an annual production of $2,000,000 of placer gold. Many of the hydraulic miners maintain that the Government put them out of business and now should assist in putting them back.

DENVER—Oct. 14

A Discovery of Tin Is Reported in the vicinity of Carbondale, Colo., where similar finds were reported several years ago. Prospectors are getting busy.

A Large Mineral Acreage in Paradox Valley, Colo., containing deposits of uranium and vanadium, has been acquired by W. A. Clark, former United States Senator from Montana. The senator upon hearing of the uranium and vanadium deposits, sent experts and engineers into the valley and they reported favorably. He then made a personal visit to the country with the result that he secured practically all the lands in Paradox Valley. He has also had experts out in Montana for several years, but they have not yet found anything sufficiently attractive for Senator Clark.

The Frantic Search for Ferberite is not made by men alone; boys are prospecting throughout the Nederland district, some of them doing very well in sorting old dumps. In one instance, while picking over Spratley mine dumps, boys disclosed apex of a vein from which they have begun shipping in small way. Tungsten properties have been soaring in price, due to remarkable rise in the market for metal. Really first-class tungsten mines are scarce. Owners of such are not willing to sell except at inflated prices. Prospects may be purchased at moderate figures but even such properties are held at prices several times figures at which they might have been secured six months ago. Alloy Steel Co, of Latrobe, Penn., through its president, W. H. McKenna, has purchased Rogers Upper Tract, 160 acres, at $1,000 per acre.

BUTTE—Oct. 14

Another Big Pay Day In Butte, on Oct. 8, when between $1,500,000 and $2,000,000 was paid out to the employees of the various mining companies. The wage scale for September was on the basis of $4 per day and although the month was a short one, with Labor Day and Sundays counted out, miners who worked throughout the month drew $100 or close to it. Anaconda company's payroll amounted to $1,090,935, Butte & Superior's close to $175,000, North Butte's was above $100,000, Elm Orlu and Timber Butte's above $50,000, East Butte's close to $90,000. This brings total of these five companies above the million and a half mark. Other smaller companies, such as the Davis-Daly, Butte-Ballaklava, Pilot Butte, Tuolumne and others, as well as industries connected with mining, brought total payroll of Butte mining district close to $2,000,000.

Aftermath of Military Régime in Butte—During the military régime in Butte a year ago, necessitated by serious labor disturbances at that time, numerous arrests were made by the military authorities, and persons found guilty of breaking the laws of the state or defying the orders of the authorities were imprisoned, fined or otherwise punished. Such persons, upon the withdrawal of the military, filed suits in the civil courts for damages against the state of Montana, totaling in all about $70,000. The first eight of these suits will be heard Oct. 15. Judge W. H. Poorman, assistant attorney-general, was in Butte Oct. 8, preparing for the trial. It is generally believed that the state will uphold the action of the officers in charge of the National Guard during the time of martial law in Butte and Silver Bow County and will deny the plaintiffs' claim that they are entitled to damages.

SALT LAKE CITY—Oct. 15

The United States Assay Offices in Salt Lake, Boise, Helena and Carson City will hereafter charge $1 instead of $3 for each metal determined, according to advices recently received from Washington. The list of determinations includes gold, silver, lead, iron, tin, zinc and tungsten. A protest has been made to the director of the mint by the assayer in charge of the Salt Lake office regarding the assaying of tin and tungsten at $1 a determination. The charge of other offices for these assays has been $5 a metal. Two months ago the local assay office was equipped for assaying ores in addition to bullion. The lower charges are expected to encourage mining and especially prospecting.

SEATTLE—Oct. 12

Gold Receipts in the Seattle Assay Office for the last quarter decreased, according to the report of the government official in charge. Receipts for the quarter this year from Alaska show $4,885,865 having been received, while last year for the same period there were $4,906,416 received.

Two New Placer Strikes have been made in the vicinity of Dawson, which have caused a considerable movement of operators. One strike was made on Rude and Dip Creeks, 20 mi. from Coffee Creek. About 150 claims have been staked and ...e discoverers report that they have got better than wages. A landing is made on the Yukon below Selkirk and a good trail is found to the new camp. The extent of the pay has not been determined. Reports from Marshall City on the Yukon tell of a new discovery being made near that deserted camp. The new find was made on Willow Creek, and the paystreak has been developed across four claims. The pay so far developed consists of an average of 7 ft. of gravel running about 12c. per pan, with an overburden of 16 ft. of muck. Practically all the ground has been staked.

"As to the Quartz Possibilities of the Fairbanks District, others may be discouraged," says Dr. Alfred H. Brooks, "but I retain the same opinion expressed some years ago, that this will yet be a good quartz camp." Mr. Brooks has recently returned to Seattle from a trip through Alaska for the United States Geological Survey and continues, "At the present time, the quartz industry is not so active as it was some time ago, but that is because the owners of the properties are waiting for cheaper fuel. As soon, however, as we get some coal there at reasonable prices, I am sure the quartz industry will be more flourishing." Regarding the much discussed antimony mining Mr. Brooks said that neither he nor anyone else in the country had paid a great deal of attention to it heretofore, as the demand for the ore was not great, but now the industry is interesting many operators. At the present time, it is being mined in a number of places where the ore is as free from lead as it is in the Fairbanks district and for that reason it is particularly valuable

LOVELOCK, NEV.—Oct. 13

In the Seven Troughs District, about 20 mi. northwest of Lovelock, new activity is being manifested. The Dalaware property, at Vernon, has been taken on bond by H. H. Hunter, of Lovelock, and Salt Lake City and Butte associates, and is being developed, and at the same time is treating ore from the dumps in the Darby mill, about 4 mi. distant. The Signal Peak property, which has been successfully operating a Tonopah two-stamp mill, is planning development. G. C. Newcomb, the manager, is now east to raise money for the exten-

sions planned. The Fairview is operating on a lease at 600 ft. in depth and is shipping. The Coalition property, at Seven Troughs, is in bonanza on the 1,400-ft. level. The vein is small but very rich. This company is operating a mill at the mine. The Mazuma, adjoining the Coalition, is idle. There is very little prospecting or development in the district, outside the above-noted properties. The veins are in rhyolite and are associated with a double system of dikes of basalt and augite andesite. The chief product is gold, although silver is generally found with the ores.

The Camp of Willard, near Lovelock, is comatose. Recently there was only one man in the camp, a watchman on the Honey Bee mine. The broad street, double lined with ephemeral structures, saloons, dance halls, real-estate offices, cafés, etc., all erected within a year, is as silent as the desert of the poets. This situation is partly due to the long dry spell which has made living and operating in the camp difficult, but chiefly due to a drought of "outside capital." The leasers, after a losing struggle to make their operations pay out of high-grade shipping ore had all left and the heralded operations of the Willard Consolidated, "parented" by a San Francisco stock-selling concern, ceased for lack of funds. However, the camp is not dead yet. Negotiations are under way for the Honey Bee property, the discovery property in the camp and leasers will resume in October on the Operman claims, adjoining the Honey Bee, and on the Sheepherder group, on the northern edge of the camp. As evidence of the cause of the boom the fosterers of Willard show documentary evidence of several carloads of $20 to $44 ore, shipped by leasers, and of several hundred pounds of "jewelry" ore, treated at the Coalition mill, at Seven Troughs. However, the explorations to date, consisting of several tunnels and drifts, and of half a dozen shafts, the deepest about 60 ft., are by no means a conclusive test of the camp. It is possible that the leasers may yet put the camp permanently on the map. It is claimed that enough mill ore has been indicated by the work to justify reviving the project for a custom mill. It is rumored that the Sears Smith Engineering Co., of Oroville, Calif., is reconsidering plans for such a mill to be erected on the flat at the railroad, about five miles from the camp.

MORENCI, ARIZ.—Oct. 10

The Clifton-Morenci-Metcalf Strike at the end of the first month, Oct. 11, is no nearer settlement than the day the miners walked out. The managers of the Detroit, Arizona and Shannon copper companies are still absent from the district and declare they will not treat with the strikers until the non-resident agitators have gone and the complete ascendancy of the Western Federation of Miners is overcome. The power houses at Clifton and Morenci are being operated for lights only, and the Eagle pumping plant, Morenci Water Co., is running one shift instead of three. All other work is stopped. Morenci Southern train makes only one trip a day between Guthrie and Morenci. About 100 troops are on the ground and more are expected daily. Except an occasional parade, the district is comparatively quiet. The effect of the Governor's first order is given in a telegram from one of the mine managers from El Paso as follows:

Governor Hunt Came to Clifton and on the same platform with the organizers of the Western Federation of Miners, made speeches of encouragement to the strikers, the effects of which were to incite them against the managers and embolden them to deeds of violence. During the ensuing days the mob of strikers became more and more demonstrative in showing their hostility against company officials, who were seized by the mob and subjected to annoyance and humiliation. The sheriff was entirely powerless to protect them in their own homes or in the discharge of their duties and was forced to place them in jail for their own protection, and as the governor had announced that he would compel the managers to treat with the Western Federation strikers even if he had to put them in jail to accomplish this, we deemed it expedient to withdraw from the affected district until such time as adequate protection to persons outside of the county jail could be assured, leaving our property in the sheriff's hands for protection.

DOUGLAS, ARIZ.—Oct. 15

The Nacozari Situation is acute and prospects for the mining companies are more than dubious. The Pilares mine of the Moctezuma Copper Co., and the concentrator at Nacozari, Sonora, Mexico, were closed down the evening of Oct. 13; all the American and a large part of the Mexican employees left for Douglas, Ariz., or Agua Prieta, Sonora, the following day. Up to the day of closing down, the mine had been producing and the concentrator treating 2,000 tons of ore per day. For the last three or four weeks operations have been carried on at this full-capacity scale, but under a feeling of tension on the part of the employees. The rumors of a Villista army approaching from Chihuahua was the cause of this, and each day these reports were announcing the closer proximity of Villa's troops to the eastern mining camps of Sonora. The climax was reached Tuesday when General Calles, the Carranza leader of the Agua Prieta forces announced that the railroad would be taken over at once by the military forces under his control; that all food supplies in the company stores would be confiscated and removed to Agua Prieta; and that all rolling stock of the railroad would be moved to that place Thursday, Oct. 14. The announcement was also made that all the Mexicans at Pilares and Nacozari were to leave with their families for Agua Prieta. These announcements were made in Nacozari the evening of Oct. 12, but it was not until noon the next day that more than a few of the mine employees at Pilares knew of them. Work was stopped at the end of the day shift and at midnight every American and all but a few of the Mexicans came down to Nacozari. Everything was hastily prepared for an indefinite shutdown at both mine and concentrator. Thursday morning at eight o'clock the first train carrying nearly all the Americans and several hundred Mexicans and their families left Nacozari, reaching Douglas at 2 p.m. Other trains followed so that by night Nacozari had been left deserted; without provisions and without a railroad car or engine. Considerable apprehension was felt on the trip out as no one knew definitely the whereabouts of the advance column of the Villista troops. It was reported that they had entered El Tigre Wednesday and it was feared that a small squad might force ahead and cut the railroad line in the vicinity of Frontera or Esqueda, before the last trains from Nacozari could pass that part of the line.

The Nacozari Consolidated has also closed down and work has been stopped at all the properties in and about Nacozari, Moctezuma, Cumpas and other points in the region. Notice was sent to all operating in these camps in time for them to make a hasty departure and reach Nacozari in time for the train. Many operators on their way out to their properties turned back and it is probable that no further work will be done for some time, possibly not for the rest of the year.

Agua Prieta Forces have been reinforced by the concentration of the greater part of the population within a radius of 100 miles, all of which has been Carranzista territory. The city is well provisioned, garrisoned and protected by breastworks, trenches and entanglements. Villa's troops are expected to move toward that city, because its taking would give Villa control of nearly the entire state of Sonora. The announcement that the Carranza government would be recognized by the United States has had the effect of making all mine operators extremely doubtful about being able to resume work so long as Villa is in control or near enough to be a menace.

PARRAL, MEXICO—Sept. 21

Owing to the Unsettled Condition of the Country and the absolute lack of mail service, mail for Mexican mining companies is being sent to El Paso, to be forwarded when conditions are more settled. On Sept. 14, a telegram from Secretary Lansing was received, advising all Americans to leave the country. On Sept. 16 a special train, sent down by the American Smelting and Refining Co. took out the entire staffs of the Mina Tecolotes y Anexas, Montezuma Lead Co., and San Francisco del Oro and part of the Alvarado Mining and Milling Co. employees. Most of the American women of the district were sent out to the States several weeks ago, when conditions looked quite threatening. The El Rayo of the Mines Co. of America has also closed down, and its employees are now in Parral, waiting for a train to take them out. Enough Americans of the Alvarado Mining and Milling Co. remained to continue the operations of the Palmilla mill and the Alfareña, Las Cruces, Sierra Plata and Preseña group of mines. This is the only company now operating in the district. There was practically no mail service for the month of September, and little improvement is expected as Villa intends to destroy the railroad from Torreon north to Chihuahua, removing the rails and good ties, and burning the old ties. The shortage of food is becoming serious; there is none in Parral nor Santa Barbara. The Alvarado has enough corn and beans to feed its men for two or three months, providing the soldiers do not confiscate it.

TORONTO—Oct. 13

Interest in the Kowkash Gold Camp shows no signs of abatement. Good showings, many of them displaying free gold, have been found at scores of points along the auriferous belt, and the district is overrun with prospectors. Many buildings are being erected and an 8-mi. winter road is being run through from the King Dodds claims to Kowkash Station, so that machinery can be brought in. To obviate confusion, the Department of Mines is having surveyed a tie line to facilitate accurate locations

The Mining News

ALASKA

ALASKA GOLD (Juneau)—Plans for working of Kensington mine next spring with 500-ton pilot mill said to be confirmed.

ANNEX CREEK TUNNEL (Juneau)—Has advanced 1,000 ft. Pipe line and concreting of tunnel being rushed. Power house practically finished.

STEVE ROWE AND NO. 9 CLAIMS (Golden)—Doctor Chase, of Cordova, owner of ground, has recently shipped in 6-stamp mill, 1,500 ft. of tram, and other machinery with intention of putting the claims on a working basis the first part of next spring, or late this fall.

SLISCOVICH ANTIMONY MINE (Nome)—Has been taken over by syndicate which will immediately start shipping 800 tons of ore now ready and proceed to develop property. Railroad between Kugarock and Nome leased so shipment can be made during winter. Several thousand tons will be ready for shipment to States with opening of navigation.

ALASKA GOLD MINING CO. (Funter Bay)—W. S. Pekovich, who has been working old Funter Bay claims, has formed million-dollar corporation to develop and mine these claims on Admiralty Island. Officers are J. R. Moore, real estate man from Seattle; A. H. Ziegler, Juneau lawyer, and W. S. Pekovich. The new company expects to increase present output and install more equipment. Mill is showing good results.

TALKEETNA MINING CO. (Valdez)—Has been incorporated for $1,000,000 by P. C. Ellsworth, 407 Pioneer Bldg., Seattle, J. L. Fulton, of Portland, and R. L. Hatcher and E. H. Barthoff, of Valdez, who have been connected with Gold Bullion Co. Properties with which new company was organized are formed of a consolidation of Matanuska holdings, Gold Mine Co.'s land and three other grants. Work in 1916 will be confined to development and blocking out ore. In winter of 1916 mill will be taken in, and put in operation following summer. Grade of ore, averages $50 gold per ton. K. I. Fulton, of Berkeley Calif., will be the Supt.

ARIZONA

Gila County

NEW KEYSTONE COPPER (Miami)—By corporate action, capital stock of company recently reduced to $39,797, consisting of 39,797 shares, par value $1 each. Only asset company now owns consists of cash in treasury. Board of Directors of company deems it advisable and to best interests of stockholders to dissolve company, and if such dissolution is authorized and approved by two-thirds in interest of all stockholders as required by law, cash then in the treasury of company will be available for distribution.

CALIFORNIA

Butte County

BUTTERFLY (Oroville)—Lease and purchase option on this property in Morris ravine secured by H. W. Tegrundy, C. F. Belding and others, of Oroville.

MUGFORD (Chico)—Property reported sold by Thomas Mugford to Charles L. Crowder and others, of Chicago. Price said to be $10,000. Mine formerly known as Eureka.

U. S. EXPLORATION CO. (Merrimac)—This San Francisco Co. is reopening Robinson mine in Granite Basin. Contemplate building 150-ton mill and 300-hp. hydro-electric plant in spring of 1916. Designs will be made this winter. Machine shop and sawmill and other complete equipment will also be installed at 1,200; shaft will be sunk to 1,400.

Calaveras County

MARJES MINING CO. (San Andreas)—Permit recently issued by State Commission of Corporations for sale of stock shares has been revoked. Permit was issued on basis of an option for purchase of Ford mine. Company forfeited option, and in order to sell stock for development of other properties it will be necessary to make new application.

Eldorado County

HOLMES LIME CO. has brought suit in Supreme Court against Fred C. Anderson, Walter S. Moore and others to quiet title to extensive lime deposit near Mountain Quarries on middle fork American River.

Nevada County

BEN FRANKLIN AND ALASKA (Grass Valley)—J. L. Claghorn, of New York, has secured bond, and work of unwatering shaft started. Property equipped with hoist machinery.

NORTH STAR (Grass Valley)—Work is progressing below 6,300 incline level. Deepening of shaft will be resumed at an early date. Third quarterly dividend this year disbursed amounting to $50,000.

POLAR STAR (Grass Valley)—Contract for installation of hoist, pump, compressor and other equipment for sinking, secured by Taylor Brothers Foundry and Engineering Co. Mine is one of old producers and has been idle for some time. Property taken over by Utah men. Oscar Coffin is superintendent.

NORTH STAR (Nevada City)—Enlargement of Providence shaft to 1,750 level is about completed. Shaft now has three compartments and has been completely retimbered and new track laid; it will be deepened to 3,000-ft. point. New hoist equipment installed. Providence will be converted into main working shaft of Champion group. Drift from Champion shaft being driven at 2,500-ft. point.

CENTRAL SOUTH YUBA (Grass Valley)—Thirty tons of copper ore shipped to Selby estimated to run 10% copper and 5% zinc. Shaft is down 100 ft. In drift 115 ft. south and 27 ft. north of shaft 4-ft. ledge has been developed. Former shipment of 40 tons returned $12 gold, $6 silver and $14 copper. About 500 tons of ore on dump ready for shipment. Cost of mining and transportation would not permit mining of low-grade ore.

Placer County

HERMAN (Westville)—Thirty-stamp mill in operation since Aug. 17, crushing ore from 300 level, some of which is high-grade. Lost vein on tunnel level was found in south drift in hanging wall and in the foot wall of north drift. This vein is in line with new oreshoot discovered on surface, 600 ft. above. James F. Grimes, of Pittsburgh, and associates, are operators. Company has 1,000,000 ft. of timber now used for fuel as well as mine timbers, but electric power is contemplated. This may be secured from Pacific Gas and Electric Co. or mine operators could install an electric power plant as availability of water is assured.

Trinity County

ASBESTOS deposits, about 12 mi. from Hayfork, reported to have attracted interest of Seattle men. Abundant water and timber available. Bert Kellogg is owner.

GLOBE CONSOLIDATED (Dedrick)—Reported that Crown-Reserve Mines Co., of Cobalt, is negotiating for control of property. Equipment includes 20-stamp mill and cyanide plant. Property has produced approximately $250,000 and has strong ore reserve.

Tulare County

MAGNESITE DEPOSIT north of Porterville reported to be under examination by Chicago men with view of purchase and operation.

COLORADO

Boulder County

U. S GOLD (Boulder)—New milling plant completed. Crushing began Oct. 3. Treatment includes crushing, roasting and cyanide leaching. Ores from Livingston and Sphinx mines of this company will be treated. Underground workings have been put in good shape and are ready for regular production.

BOULDER TUNGSTEN PRODUCTION CO. (Nederland)—New crosscut tunnel started with portal below great dam of Colorado Power Co. If continued on its present northwesterly course through Hurricane Hill, will intercept many tungsten veins at depths up to 1,000 ft. For more than mile tunnel will be within property lines of this company. If continued further, it will develop the ground of Wolf Tongue and Primos companies. This is first tunneling project in this district and is undertaken by an "independent" company not purchasing custom ores. Mill will be erected at mouth of tunnel when such plant is warranted. Superintendent, Fred H. Nye.

Gilpin County

EAST NOTAWAY (Russell Gulch)—This mine, producer of rich ore for many years, closed down year ago by litigation, has been finally secured by opposing litigant Colma Mining Co., and will be reopened under superintendence of R. C. Benight.

Lake County

MATCHLESS (Leadville)—The third fire within 14 months destroyed the shafthouse and equipment, Oct. 10. This is the mine from which late Senator H. A. W. Tabor took fortune and it is still owned by his widow who lived in cabin destroyed in this last fire. Incendiarism is suspected. Leasers Avon and Springhetti had just put mine in readiness for shipping.

DERRY RANCH (Leadville)—The 6-cu.yd. dredge, built by the New York Engineering Co., went into commission Oct. 9; first cleanup Oct. 16, about $7,000; estimated yardage, 17,000 cu.yd. Heating plant now being installed preparatory to cold-weather operation. Dredge owned by Derry Ranch Gold Dredging Co., of which A. C. Ludlum, president of New York Engineering Co., is president and principal owner.

San Miguel County

TOMBOY (Telluride)—Erection and equipment of new cyanide plant are proceeding rapidly.

Summit County

ST JOHNS (Montezuma)—By way of experiment from [illegible] this mine's complex ore, large shipment is being made to Salida for smelting and another large lot will be tested by concentration methods including flotation.

WELLINGTON (Breckenridge)—Flotation equipment is being installed in wet mill to treat tails from present apparatus. Mine produces 150 tons daily. Cable fire-protection service is being installed, equipment consisting of 50,000-gal tank placed about 500 ft. up mountain with ample [illegible]

Teller County

PORTLAND (Victor)—Good ore has been [illegible] 1,900 level. About 40 sets of leasers working.

EL PASO (Elkton)—September production [illegible] carloads, about 2,600 tons. New shoot 3½ ft. [illegible] opened on 500 level in Ajax vein and [illegible] averages about 1.25 oz. per ton.

AJAX (Victor)—September production, entirely by leasers, totaled 1,015 tons, average value of $17.20 per ton. Mill is being remodeled somewhat and sampling machinery installed preparatory to starting up again, on custom basis.

VINDICATOR (Independence)—On 1,800 level, rich strike has been made in what is called No. 1 North vein. Dalzell lease, 800 level, produces two carloads of 1-oz. ore per week. Total September production from this mine was 195 carloads (5,850 tons); record for this company. Of this, leasers are credited with 41%, averaging 1 oz. per ton. Golden Cycle mine, now owned by Vindicator company, shipped 230 carloads, all consigned to Golden Cycle mill at Colorado City. Of this production, leasers mined 52%.

IDAHO

Shoshone County

STANLEY (Burke)—From upper level of this Day-controlled property antimony ore is being stoped and sorted for shipment. Contract has been let to Edward Reese for crosscut tunnel at lower level.

BIG CREEK LEASING (Kellogg)—Contract has been let to John Melise to drive 480-ft. raise from lower tunnel to connect with orebody in upper workings. Ore recently found carries 30% lead and 380 oz. silver per ton.

HYPOTHEEK (Wallace)—A 12-in vein of high-grade galena has been found in crosscut to vein on 1,100 level. No work will be done to prospect this unexpected deposit till main vein has been cut and its possibilities determined.

RAY-JEFFERSON (Wallace)—Capital stock of company has been increased from $1,500,000 to $2,000,000, funds from sale of new issue to be applied to winter development work and building of new 250-ton mill. Reported that entire issue was taken by men who were already heavy stockholders. Work on mill, it is announced, will commence as soon as snow flies.

CŒUR D'ALENE ANTIMONY (Kellogg)—Mine is near mouth of Pine Creek, about mile from railway. Forty-ton car of ore carrying 50% antimony has been shipped. Ore is blocked out and stoping is under way on three levels. At 150-ft. level of main shaft vein is 5 ft. wide and averages 50% antimony. Rock crusher and three jigs will be added to mill equipment. Twenty men are employed.

SILVERADO (Osburn)—Property comprises group of lead-silver claims near Osburn. At Spokane meeting of stockholders W. P. Pinkrell was elected president, Wm. Wood, vice-president, and C. D. Muxen secretary-treasurer. Arrangements have been made with Washington Water Power Co. for current and compressor will be installed soon. Winze is down 110 ft. from inner end of 4,000-ft. working adit.

SUCCESS (Wallace)—Stringer of silver-lead ore recently found on 1,200 level, assaying 60% lead, 10% zinc, and 60 oz. silver, across 16 in., is first lead ore to be discovered in this mine. Stringer lies on footwall below 7-ft. body of zinc ore. An entirely new oreshoot has been tapped by crosscuts on 500 and 800 levels; raise has been driven on this from 800 to the 700; will be extended to 500. As soon as new pump is installed at 1,200, shaft will be sunk to 1,400.

MARSH (Burke)—Operations at this mine delayed by unusual flow of water from crosscut to Got-Em-Now lode. Owing to inadequate pumping capacity water is collecting in lower workings. New pump of 400 gal. per min. capacity has been ordered and will be installed at 900 level, where station 50 ft. long, 25 ft. wide and 20 ft. high has been cut. Mill on Ninemile, near Wallace, has been overhauled and its capacity increased from 150 to 200 tons. Callow flotation process has increased saving by $1.25 a ton. September shipments were 200 tons of crude ore and 600 tons of concentrate.

HIGHLAND-SURPRISE (Kellogg)—After trial run of three cars of ore at new 100-ton mill of this Pine Creek property it was decided to use electric power instead of steam. Ore is now being taken from stope opened last winter in Surprise ground. Ore from Highland-Chief is being stored pending settlement of certain difficulties that arose at time of consolidation of old Surprise and Highland-Chief. Drift from Surprise into Highland-Chief ground has been driven 1,000 ft. and has cut shoot of ore averaging 14% lead, 19% zinc, and 6.6 oz. silver per ton; this drift is 126 ft. below Highland tunnel and raise shows continuous ore between levels.

MICHIGAN

Copper

CALUMET & HECLA (Lake Linden)—Regrinding plant at Lake Linden produced, during month of September, at rate of 4,000,000 lb. of copper per annum. This copper was produced at reported cost of 4c. a pound.

ARCADIAN (Houghton)—Tenth level opening is getting into better looking rock. Nothing is being done at present on conglomerate formation which was opened several months ago. Progress in crosscut from testpit, to gain knowledge of New Baltic vein is good.

CENTENNIAL (Calumet)—Self-appointed committee of Lake Superior shareholders held meeting last week at which it was definitely decided to wait and see what happens to Tamarack deal with Calumet & Hecla before going further with their plans of approaching Osceola Cons. in regard to selling out to Osceola.

HOUGHTON COPPER (Houghton)—Is maintaining average of 28 lb. refined per ton from rock coming from 10th level. Is showing better than anticipated. In addition to daily shipment of two cars of rock to Winona mill, operations at Houghton include sinking from 10th level winze. At point where sinking started, richest rock anywhere in this property was encountered.

WINONA (Winona)—Continues to operate on limited scale and to secure better than 18 lb. refined copper per ton, which is best showing ever made on this property. Experiments with leaching processes continuing with evidence of ultimate success. Winona rock is different from any other in district and requires distinct treatment. Manager Seeber has been persistently experimenting to find best concentrating and leaching combination.

QUINCY (Hancock)—Will make no effort to re-open Pontiac shaft this winter, according to present plans. That is not due to any fear as to merit and value of Pontiac tract, for levels from Mesnard, running north are all in best looking ground to be found anywhere in northerly section of the Quincy's numerous shafts. Three shafts are keeping up daily tonnage that is equal to past performances.

VICTORIA (Victoria)—Is handling average under 450 tons of rock daily and this is now running 12 lb. per ton. About as lean as any rock in Lake Superior district and is profitably handled simply because of water power and economical management. The rock has averaged as low as 11 lb. but it is believed that little closer selection in larger openings can make it come up to 13 lb. There is one 700-ft. lateral that is in the best looking rock that the property has opened. Work of building larger shaft, beside one now utilized, is going forward at six different levels at same time and will take about five months more to complete. That will be followed by installation of rolls in stamp mills with result that company then can hoist and mill product at least 30% larger than at present. The company recently has made some land purchases in vicinity of dam.

Iron

ROLLING MILL (Negaunee)—Orders have been received to ship 100,000 tons from stockpile. This will be first to be moved this year.

CLEVELAND-CLIFFS IRON (Ishpeming)—Diamond drill has been placed in commission just to west of North Lake, Barnes Land Co. owns land.

BALTIC (Iron River)—Mine is being reopened by Pickands, Mather & Co. About 150,000 men will be employed by Nov. 1. Water is now being drained and bailed.

L. S. & I. RY. (Marquette)—Record was established at new dock on Sunday, Oct. 10. Over 42,000 tons were sent out in one day. Eight vessels were loaded. A shortage of cars and boats is causing companies considerable concern. Cleveland-Cliffs Iron Co. is hard after wild carriers and believes that all of ore sold will not be moved this season.

MINNESOTA

Cuyuna Range

IRON MOUNTAIN (Manganese)—First cargo of this mine's product will leave Soo Dock, Superior, Wis., on Oct. 16. Management plans sinking shaft to greater depth with view to increasing output.

Duluth

DULUTH & IRON RANGE RY.—Final plans have been prepared for $1,500,000 steel and concrete ore dock to replace present No. 2 and No. 3 docks. New dock will be similar to No. 1 dock and will have storage capacity of 68,000 tons. During construction, old No. 2 dock will be demolished but No. 3 will continue in operation until new dock is ready.

Mesabi Range

MINORCA (Biwabik)—After shipping 447 cars in September, operation has ceased, all machinery having been moved to other operations in district.

MOHAWK (Aurora)—Workings now being pumped out. Mining to be resumed. Has been idle over a year. Steam shovel started shipping ore in stock this week. Employment will be given to 100 men throughout winter.

EUCLID (Chisholm)—Ground at west end of pit is caving again. Several large holes have appeared in middle of Central Ave. in city. Old drifts that run under town were supposed to be filled, but settling is occurring. Mine has been idle several years.

CROSBY (Nashwauk)—Mill is now about completed. Building is 62x57 ft. Extreme height is 81 ft. Plant is one-half unit in size. All of machinery driven by individual motors. Very little shafting and belting in evidence. All machinery furnished by Allis-Chalmers Co. Mill will probably not go into active operation for several months.

VIRGINIA—H. A. Rogers, of General Electric Co. is here to electrify shovels of one of mining companies. There are few such shovels in operation on Mesabi now. It is claimed that they are being operated successfully at Utah Copper, in Bingham. In the past, trouble has come from heavy strain on motors at time the dipper was getting its load. It is stated that this fault has been overcome.

MISSOURI-KANSAS-OKLAHOMA

Zinc-Lead District

ANCHOR MINING CO. (Lincolnville, Okla.)—Is building new 200-ton mill on lease on Buck land.

WHITE EAGLE (Baxter Springs, Kan.)—Last week made 4 cars of ore, 160 tons; will make about same this week; largest producer in district. Homer Seals is superintendent.

JOHN HUFFMAN, ARTHUR BABE AND RAMSEY BROS. (Galena, Kansas)—Have taken lease on Murdock land northwest of Galena. Will install pumps to drain ground. Land worked formerly at shallow depth. Present company will go to lower level, where good ore is known to exist from result of drilling some years ago.

EMMETT MINING CO. (Joplin, Mo.)—Has succeeded in draining its land east of Joplin to 4ower level. Has been pumping for several months; ground been idle for years on account of water. Has found good run of ore. New 150-ton mill will be built at once. Immense pile of dirt has been broken down and ready to hoist; work will be conducted on the 120-ft. level while mill is being built. At 90-ft. level, face of good ore has been blocked out 300 ft. long and 30 ft. high.

MONTANA

Beaverhead County

BOSTON & MONTANA DEVELOPMENT (Elkhorn)—Tunnel has now reached length of 2,000 ft. and is within 300 ft. of principal veins. Financing of proposed railroad to mines has been delayed due to fact that London financiers who were backing enterprise are obeying orders against outside investments since war broke out in Europe.

Deer Lodge County

WASHOE REDUCTION WORKS (Anaconda)—Fifth section of concentrator is nearly remodeled and will soon be adding to output from flotation plant. New roaster building is half completed and experimental zinc plant is practically ready for first run. New reservoir is being constructed for fire protection, located above buildings to give high pressure in mains. Five pulverized-coal-fired reverberatory furnaces are in operation and work is progressing rapidly on other three. Ninth reverberatory is being installed in converter building to re-treat converter slags.

Fergus County

BARNES KING DEVELOPMENT (Kendall) — Approximately 2,900 tons of ore were mined during September with estimated gold output amounting to between $15,000 and $16,000. This is about same as in August, although tonnage is larger and returns per ton less, amounting to between $5 and $6 against $9 per ton in August. Some accumulated low-grade ore run through mill in September reduced average value. At Piegan-Gloster mill near Marysville, Lewis and Clark County, low-grade ore is being milled. Returns for September between $10,000 and $12,000. Total receipts from gold shipped by company to Helena assay office will be between $25,000 and $30,000.

Silver Bow County

NORTH BUTTE (Butte)—Fourteen men were killed at Granite Mountain mine on Oct. 19 by an explosion of 500 lb. of dynamite. Eight men were seriously injured, one probably fatally. Cause of explosion has not been determined.

DAVIS-DALY (Butte)—Returns on shipments during past two weeks show average of about 7% copper. Shipments are being increased and for October may average 125 tons per day.

BUTTE-ALEX SCOTT (Butte)—Oct. 6 operations were resumed after shutdown of nearly two months during which numerous improvements were made. Shaft was sunk 220 ft. and station started on 2,200-ft. level. Hoisting plant was adjusted to take care of future increase in output and shaft was equipped with skips to replace cage and cars used heretofore.

NEVADA

Nye County

TONOPAH ORE PRODUCTION for week ended Oct. 9, amounted to 9,583 tons, valued at $198,454, compared to 9,496 tons week previous. Producers were: Tonopah Belmont, 2,724 tons; Tonopah Mining, 2,850; Tonopah Extension, 1,850; West End, 921; Jim Butler, 1,100; and miscellaneous leasers 138 tons.

Storey County

CROWN POINT-BELCHER (Gold Hill)—Water was lowered and incline repaired below 1,600 level. Jacket mill received 750 tons of dump rock and shipped 2 bars of bullion to smeltery. Saved 42 cars of mill rock from stopes in 1,300 Belcher raise.

MEXICAN (Virginia)—Southwest drift from No. 3 extended 12 ft. to 26-ft. point; face shows 4 ft. of quartz of low assay value. East crosscut No. 3, 2,700 level, is in porphyry and quartz. Mexican mill treated 270 tons of ore, average assay value $9.48 per ton.

CON. VIRGINIA AND OPHIR (Virginia)—On 2,700 level joint west crosscut has been started and advanced 12 ft. through porphyry. On 2,500 level Ophir sunk two-compartment winze 5 ft., making total depth 11 ft. Saved in Central tunnel 307 cars of ore from stopes and development work and milled 250 tons.

UNION CON. (Virginia)—Saved in raise No. 1 stope 32 cars of ore averaging $20 per ton. Top of raise is 54 ft. above sill floor. In stope No. 3, 88 cars of ore worth $13.60 per ton saved from old fill. Mill Union and Sierra Nevada continued repairs in southwest drift on 2,500 level. Sierra Nevada west crosscut advanced 10 ft.; face showing porphyry and quartz of low assay.

UTAH

Beaver County

PALOMA GOLD AND SILVER (Milford)—At meeting of directors, held Oct. 4, it was decided to sink shaft additional 100 ft. Contract for this work has been given.

Juab County

QUARTZ LEDGE, recently disclosed on O. M. Henry ranch, producing good ore, which is being hauled to Central Eureka mill for crushing treatment.

TINTIC STANDARD (Eureka)—Work is being done on 1,350 level, which is reached by inclined winze in vein. Fissure carries quartz, which is at present barren. Seven men are working.

IRON BLOSSOM (Silver City)—Shipments for first nine months of year amount to 754 cars, or about 36,000 tons, making monthly rate of about 84 cars. Week ended Oct. 8 there were shipped 21 cars

Salt Lake County

CARDIFF (Salt Lake)—Daily shipments of from 100 to 125 tons are being made. Telephone line is being built to property from Alta. Parts of new machinery have been delivered, but compressor is not yet installed.

MONTANA-BINGHAM (Bingham)—Conger vein has been cut in Bingham Amalgamated ground by this company's tunnel, and development work will begin at once with considerable force. As soon as this is well under way, tunnel, now in 4,048 ft., will be continued to cut Keystone and Fortuna veins.

UNITED STATES MINING (Bingham)—About 400 tons of ore produced daily from this company's Bingham properties. Most of this is a lead-zinc ore, which is treated at concentrator and Huff electrostatic plant at Midvale. Zinc is shipped to company's recently acquired zinc plant in Kansas. About 50 tons daily of copper ore is produced.

MICHIGAN UTAH CONSOLIDATED (Alta)—This company is advertising for bids for 1,000-ft. extension of its Hot Air drain tunnel. Dimensions are 5x7 in clear. Air, compressorman, blacksmith shop, drills and steel, cars, rails, shoveling sheets, and ventilating pipe are to be furnished. Contractor shall furnish labor, powder, fuse, caps, picks, shovels, and blacksmith coal, and shall drive tunnel under supervision of company.

Summit County

PARK CITY shipments for the week ended Oct. 8 amounted to 1,493 tons.

NEW QUINCY (Park City)—Crosscutting is being done from 90-ft. raise above 900 level of Daly West. Two shifts are being worked.

SNAKE CREEK TUNNEL (Park City)—Face is in 12,700 ft. Progress of 345 ft. was made during September. Tunnel is 3,730 ft. from surface, having reached point of greatest depth to be attained.

SILVER KING CONSOLIDATED (Park City)—During September output averaged 540 tons a day. Earnings for July, August, and September amounted to $188,000, which is nearly equal to three quarterly dividends of $63,000. Ore is bringing about $40 a ton, net smelter returns.

Tooele County

CONSOLIDATED MERCUR (Mercur) — Dividend of $6,000 has just been paid from sale of parts of old mill at this mine. Report covering period from July, 1912, to Jan. 31, 1913, stated that operations were being carried on at loss, and mine closed down. In 1913 and 1914 dividends amounting together to $50,000 were paid from accumulated surplus. Company has been selling off machinery, etc. It still owns mining ground.

WASHINGTON

Spokane County

WASHINGTON STEEL AND IRON CO. (Spokane)—Is completing plans for erection of 100-ton iron-ore furnace in Leavenworth district. Oliver P. Moore is secretary of company.

WISCONSIN

Zinc-Lead District

POLLARD & SAXE (Linden)—Wallace mill at Highland is being removed to Gillman mine at Linden.

STEPHENS & KISTLER (Platteville)—Construction of 100-ton mill has been begun on Cruson property at Platteville.

GREAT WESTERN (Galena)—This company is moving roaster equipment from Brown-Croft mine at Shullsburg to its property at Galena.

OLIVER IRON MINING (Shullsburg) — This company is sinking shaft and assembling material for 400-ton mill on Mulcahy land near Shullsburg.

WISCONSIN ZINC (Platteville)—Rich cuttings of jack were found in first hole drilled on Chas. Aston tract of 280 acres, formerly Ivo, midway between Benton and Shullsburg. This company has also taken over old Ida-Blende site near Benton.

CANADA

Ontario

ORE SHIPMENTS OVER THE T. & N. O. RY. for the month of September, 1915, from Cobalt proper were Beaver, 53 tons; Buffalo, 351; Cobalt Comet, 51; Conigas, 37; Crown Reserve, 79; Kerr Lake,45; La Rose, 130; McKinley-Darragh, 195; Mining Corporation of Canada Ltd., Cobalt Lake Mine, 172; Townsite City, 102; O'Brien, 74; Penn Canadian, 63; Peterson Lake—Seneca Superior Ore, 143; Temiskaming, 42; from New Liskeard, Casey Cobalt, 34; total silver ore shipments, 1,576 tons. From South Porcupine, Dome Lake (gold), 31; from Porquois Junction, Alexo Mine (nickel), 584 tons.

CANADIAN MINING CORPORATION (Cobalt) — For four weeks ended Aug. 12, value of production from different mines was £40,420 of which £19,272 was profit.

DOME (Porcupine) — September production was $139,000 from 28,500 tons of ore; an average recovery of $4.87 per ton. Work of doubling capacity of mill proceeding rapidly.

CROWN-RESERVE (Cobalt)—Has been investigating Globe mine in California with view to purchase. It offers to pay off obligations of the Globe company out of profits of mine and give Globe shareholders a 45% interest in company.

HOLLINGER (Porcupine)—Report for four weeks ended Sept. 9 shows gross profits of $149,935. Mill treated 39,731 tons of ore of which 11,559 tons came from Acme. Average value of Hollinger ore was $9.03. Total operating costs were $3.35 a ton.

Quebec

NORTH AMERICAN MAGNESITE CO., 180 St. James St., Montreal, is working magnesite deposits in Grenville township. The plant for burning and preparing the mineral is at Calumet.

CONSOLIDATED MINING AND SMELTING CO. OF CANADA, LTD. (Montreal)—Has received two-year contract for its output from home government and will put $500,000 into new zinc reduction and copper refining plants.

Yukon Territory

THOMAS P. AITKEN (Mayo Landing, Stewart River)—Will install air compressor and hammer drill at his property, taking material in this fall. Aitken is well known and prosperous miner of Dawson and Fairbanks days.

AFRICA

Transvaal

GEDULD PROPRIETARY MINES, LTD. (Johannesburg)—Board of Directors has decided to immediately increase the capacity of the reduction plant to enable it to crush 40,000 tons per month. The increase will be so made as to permit of a still further addition at a minimum of expenditure, and development will be continued at full speed with this end in view. It is expected that the increased plant will be in operation before the end of the next year. The expenditure involved will not interfere with the payment of dividends, as the necessary funds are in hand.

The Market Report

Metal Markets

NEW YORK—Oct. 20, 1915

All of the principal markets were quiet during the last week without material change in prices.

Copper, Tin, Lead and Zinc

Copper—This market is in a rather chaotic condition. Certain producers who were fortunate in having large stocks of copper abroad have continued to make excellent sales out of warehouse there, and being satisfied with that business have made no effort to do anything here. Other producers in selling for export find it difficult to arrange for freights and are taking chances on freight rates and exchange, their probable net return being a good deal a matter of guesswork. However, they are not disposed to draw fine points about this; for everybody is desirous of selling copper and the present price is lucrative no matter if there be a difference of half a cent a pound in realizations. Operations in the domestic market are conducted with somewhat the same spirit. During the last week a rather large quantity was reported as having been sold by Lake producers on the basis of 17⅞c., cash, New York, which is figured as corresponding with electrolytic at about 17.80c. Lake producers apparently took the bulk of the business, producers of electrolytic finding it rather difficult to make sales in spite of offering at material concessions. Some producers were disposed to take business whenever and however they could get it. In the early part of the week some sales were made at 17.82½c., regular terms, corresponding with about 17.62½c., cash, New York, but on Tuesday and Wednesday copper became available from some quarters at 17¾c., regular terms, equivalent to 17.55c., cash, New York.

Copper Sheets are quoted about 23c. per lb. for hot rolled and 24c. for cold rolled, with usual extras. Wire prices are unsettled; quotations may be put at 19¼@19¾c. per lb. at mill. The chief maker does not quote base price.

Visible Stocks of Copper in Europe on Oct. 15: Great Britain, 18,087; France, 1,905; afloat from Chile, 525; afloat from Australia, 3,200; total, 23,817 long tons, or 53,350,080 lb. This is a decrease of 5,167 tons as compared with the Sept. 30 report.

Imports of Copper in the United States for the week ended Oct. 2 are reported by the Department of Commerce as follows: Metal, 9,858,736 lb.; in ore and matte, 3,600,571; total, 13,459,307 lb. The larger imports were from Chile, Canada, Japan and Spain. Exports for the week were 16,489,622 lb., the larger shipments being 7,628,452 lb. to Russia, 4,686,763 lb. to England, 2,576,804 lb. to Italy and 1,402,623 lb. to France.

Tin—This market was quiet, but there was a steady demand and a fair volume of business was reported done. Stocks apparently are being absorbed. Talk about the prospective British duty has died out.

Banka tin production for the five months, Mar. 1—July 31, was 3,550 long tons, a decrease of 170 tons as compared with the corresponding period last year.

Lead—A rather large business was done, but the market exhibited a considerably mixed situation. In New York heavy transactions were made at 4.50c., and in St. Louis at about 4.42½c. On sales for export a premium could be readily obtained, but there was difficulty in arranging such sales owing to the scarcity of freight room. Premiums over the schedule prices of the A. S. and R. Co. were also realized in other markets, Philadelphia, for example. On the other hand, in selling for delivery in Pittsburgh, there was sharp competition.

Spelter—A moderately large business—several thousands of tons—was done during the week at an average of about 12⅜c., basis St. Louis. A far larger proportion of this business was done for delivery during the fourth quarter of 1915 than was the case in the previous week. Many of the producers made offers to sell for delivery in the first quarter of 1916, but the interest of buyers in such deliveries was less marked than it had been. On the other hand, several producers preferred to confine their sales to the immediate quarter. Of the business done during the week, by far the larger proportion, say, 80 or 90%, was for export, especially to France.

Zinc dust is quoted at 25@30c. per lb. One sale was reported at 28 cents.

The ore sales of the Amalgamated Zinc Co. to American smelters have been as follows: New Jersey Zinc Co., 1,000 tons; American Zinc, Lead and Smelting Co., 2,000 tons; Robert Lanyon Zinc and Acid Co., 2,000 tons; Granby Mining and Smelting Co., 1,000 tons, and Edgar Zinc Co., 50,000 tons. Other sales are pending. The first cargo of ore for the Edgar Zinc Co. (destined for Donora) has been delivered at Mobile.

Zinc Sheets—Business has been active, sales good but with no material change in quotations. The base price for carload lots is $16 per 100 lb. f.o.b. Peru, Ill., less 8% discount.

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St. Louis is given as the basing point. St. Louis and New York are normally quoted 0.17c. apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars. Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash. The difference between the price delivered and the New York cash equivalent is at present about 0.20c. on domestic business. The price of electrolytic cathodes is 0.05 to 0.10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands. Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St. Louis being the basing market. We quote the New York price at 17c. per 100 lb. above the St. Louis price.

Silver quotations are in cents per troy ounce of fine silver.

Some current freight rates on metals per 100 lb. are: St. Louis-New York 17c., St. Louis-Chicago, 6.3c., St. Louis-Pittsburgh, 13.1c.

LONDON

Oct.	Silver	Copper Standard Spot	Copper Standard 3 Mos.	Copper Electrolytic £ per Ton	Copper Electrolytic Cts. per Lb.	Tin Spot	Tin 3 Mos.	Lead £ per Ton	Lead Cts. per Lb.	Zinc £ per Ton	Zinc Cts. per Lb.

19	23 1/16	72⅜	73⅛	88	18 39	152¼	153¾	24 7/16	5 12	63	13.18
20	23⅞	73	73	88	18 37	152¼	154	24½	5.14	63	13.16

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 3 per cent. discount. For convenience in comparison of London prices, in pounds sterling per 2240 lb., with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4.80. £15 = 3.21c.; £20 = 4.29c.; £30 = 6.43c.; £40 = 8.57c.; £60 = 12.85c. Variations, £1 = 0.21½c.

Other Metals

NEW YORK—Oct. 20

Aluminum—Conditions remain about the same as for several weeks past. Metal for early delivery is scarce, stocks being very low. The American producer has none for sale for some months. Quotations are high, 57@60c. per lb. being quoted for No. 1 ingots, New York.

Antimony—Business has been more active than for some time. Demand is good and the market is firm, with a tendency to advance. The ordinary brands are held at 29@29½c. per lb., New York, while 45@46c. is asked for Cookson's. The shipments of Chinese which were held up in the Panama Canal have been ordered to San Francisco.

Nickel—Quotations for ordinary forms are nominally 45@50c. per lb., according to size and terms of order. A premium of 3c. per lb. is charged for electrolytic nickel.

Quicksilver—Demand is fair and stocks are rather low, so that prices remain firm and are inclined to advance. The New York quotation is $92@94 per flask of 75 lb. for large orders, $93@95 for smaller quantities. San Francisco reports by telegraph an advance from $87.50 early in the week to $90@92 per flask today. London price remains £15 10s. per flask, with the same quotation from jobbers.

Gold, Silver and Platinum

NEW YORK—Oct. 20

Gold—A shipment of $25,000,000 gold from London has arrived at New York, by way of Halifax. The gold being in British coin was sent to the Assay Office as it arrived.

Transvaal gold production in September is reported at 776,750 oz., being 2,013 oz. less than in August, but 74,580 oz. more than in September, 1914. For the nine months ended Sept. 30 the total production was 6,733,916 oz., or $139,190,044, being 500,497 oz. more than last year.

Platinum—The situation has not been relieved by any new arrivals, and stocks remain low. Sales to jewelers are at a stand for the present. Quotations are a little unsettled, but very firm, with no present prospect of a break. Refined platinum is $51@55 per oz., New York, while $55@59 is asked for hard metal.

Silver—The market has ruled steady and quiet without special feature the past week, the demand being sufficient to take care of offerings. It closes steady at 23⅞d. in London.

Zinc and Lead Ore Markets

PLATTEVILLE, WIS.—Oct. 16

The base price paid this week for zinc ore was $80@75 per ton for 60% grades. The base price paid for 80% lead ore was $54 per ton.

SHIPMENTS, WEEK ENDED OCT. 16

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	5,393,170	280,790	593,080
Year	158,242,580	5,276,910	21,707,850

Shipped during week to separating plants, 5,929,300 lb. zinc ore.

JOPLIN, MO.—Oct. 16

Blende, high price, $88; base per ton of 60% zinc, premium ore, $85; medium grades, $84@80; lower grades, $79@75; calamine base per ton of 40% zinc, car lots, $60@55; average selling price, all grades of zinc, $81.18 per ton. Lead, high price, $54.90; base per ton 80% metal content, $55@50; average, all grades of lead, $51.07 per ton.

SHIPMENTS, WEEK ENDED OCT. 16

	Blende	Calamine	Lead	Values
Totals this week..	12,596,020	518,400	1,976,360	$575,930
Totals this year..	457,285,840	34,226,180	71,482,310	$20,135,930

Blende value, the week, $511,320; 42 weeks, $17,479,530.

Calamine value, the week, $14,150; 42 weeks, $783,070.

Lead value, the week, $50,460; 42 weeks, $1,875,380.

The shipment this week of purchases of the previous week is a large one, but the buying this week indicates a small shipment for the ensuing week.

Iron Trade Review

NEW YORK—Oct. 20

Domestic orders are coming in more and more to fill up the mills, already pretty well supplied with contracts for export business.

The railroads are evidently persuaded that they have held back too long; orders for rails and cars have been coming in freely. Structural-steel orders are looking up. Plates and shapes are in demand for car, bridge and ship work, and more are expected to come soon.

Mills are rather holding back on next year business, largely owing to the general expectation of higher price. The Steel Corporation's tonnage statement seems to indicate that it has taken more orders running into 1916 than most of the independents, but nothing definite can be determined.

The pig-iron market is generally strong. Steel-making iron is in demand. Foundry iron is holding back a little, but demand there is increasing also.

Imports at Baltimore for the week included 922 tons ferromanganese from Liverpool; 6,200 tons manganese ore from Brazil.

PITTSBURGH—Oct. 19

Pressure to place specifications for finished-steel products has increased further, while there is a fair volume of orders going for specific tonnages. At the present rate the mills are bound to fall farther and farther behind in deliveries, and the condition makes them indisposed to book open contracts for first quarter or first half. Under similar conditions in previous price movements the mills would have sold freely for deliveries farther and farther ahead, but at this juncture they prefer to keep their forward tonnage and take advantage of further price advances. Finished-steel prices have now advanced substantially as much on this movement to date as they did from the bottom to the top of the 1912 movement, and the advancing tendency has become more marked instead of dwindling.

Oct. 15 the Carnegie Steel Co. advanced its minimum price on bars, plates and shapes from 1.40c to 1.45c. Some other mills had already made such an advance and on the Carnegie announcement the remaining mills followed, making 1.45c. the market, against 1.05c. last December. Mills are reserved about contracting and the market may be 1.50c. within a few weeks. The leading sheet interest yesterday announced an advance in bessemer black sheets from 2c to 2.10c., and all other mills are expected to follow promptly. Openhearth are quoted as high as 2.20c. An advance in wire products is expected in the very near future.

Railroad buying has increased, there being a particularly insistent demand for prompt steel to be used in car and locomotive repairs. The Philadelphia & Reading has just ordered 2,000 freight cars and predictions are made that car buying will be very heavy in the next two months.

August exports of tonnage products of the iron and steel industry amounted to 401,000 gross tons, showing a continued increase, and October exports will probably amount to fully 450,000 tons. Including iron and steel taken by manufacturers of goods for export, machinery, automobiles, cars and locomotives, shells, etc., iron and steel is now going into export channels at the rate of about 8,000,000 tons a year, and of this about 7,000,000 tons is rolled steel, representing about 25% of the current rolled-steel output.

All the indications are that steel will grow scarcer and prices will continue to advance. Considering the character of much of the demand it is not expected, in most quarters, that advancing prices will curtail consumption to a material extent. Fundamental conditions are held to be different from those obtaining in other times.

Pig Iron—There is a slightly better demand for foundry iron, but there is no general buying movement. Consumers seem to be well covered for this year and to have no particular fears about supplies for the future. The West Penn Steel Co. has bought 10,000 tons of basic, for first-quarter delivery, from Rebecca furnace at Kittanning, which is to blow in before January. The Marshall Foundry Co. is understood to have practically closed for 10,000 tons of bessemer for first-half delivery at $16, Valley, and some sellers profess surprise that iron for such delivery could be obtained at the prevailing market for early shipment. We quote: Bessemer, $16; basic, $15; foundry and malleable, $14.50@15; gray forge, $14.25@14.75, f.o.b. Valley furnaces, 95c. higher delivered Pittsburgh.

Ferromanganese—Prospects of delivery of English ferromanganese upon contracts now being offered by sellers appear to be somewhat less uncertain than a few weeks ago and the market is less nervous. We quote contract at $100 for imported and $115 for domestic, with prompt lots going at intermediate figures.

Steel—There are no offerings of soft openhearth billets, as the mills can make so much more money on special steels for war purposes, fancy prices being readily obtained for billets to be rolled under specifications that are not particularly difficult to meet. A sale of 9,000 tons of billets for rolling shell rounds has just been made at $50, Youngstown, and there are rumors of bids of $55. Bessemer billets are quotable at about $25, Youngstown. A broader market for bessemer billets and sheet bars is expected, when consumers of ordinary soft steel cannot secure openhearth. Rods are quotable $1 higher at $32, Pittsburgh.

FERRO-ALLOYS

Ferromanganese is quoted at $110@115 per ton for domestic 80% material.—**Spiegeleisen** has been sold at $27 per ton for 20%, at furnace.—**Ferrosilicon,** 50%, is quoted at $75 per ton at Pittsburgh. Bessemer ferrosilicon is from $20 per ton for 10% up to $24 for 14%, all at furnace.

IMPORTS AND EXPORTS

Imports and Exports of those articles of iron and steel which are reported by weight, and exports of machinery for August and the eight months ended Aug. 31, are reported as follows; iron and steel in long tons; machinery by values:

	August		Eight Months	
	1914	1915	1914	1915
Imports, iron and steel	28,572	27,560	195,826	152,183
Exports, iron and steel	86,598	401,298	1,046,347	2,077,783
Machinery, value	$4,759,663	$11,439,291	$67,322,446	$79,396,113

For the eight months tonnage imports decreased 43,643 tons, or 22.3%; while tonnage exports increased 1,033,436 tons, or 98.8%. Mining machinery was valued at $4,358,245 this year.

Exports and Imports of Secondary Metallic Products in the United States, seven months ended July 31, in pounds:

	Exports		Imports	
	1914	1915	1914	1915
Copper sulphate	6,848,978	9,869,280	.....	
White lead	11,054,662	13,764,343	.....	
Zinc oxide	17,834,431	25,473,850	.....	
Zinc dust	37,122	249,868	2,645,638	818,081
Zinc dross	648,631	6,654,425	.....	

Exports of zinc dust were all reëxports of foreign material.

Imports and Exports of Metals in Great Britain other than iron and steel, are reported as follows for the eight months ended Aug. 31, in long tons:

	Imports		Exports	
Metals:	1914	1915	1914	1915
Copper	111,776	146,990	39,035	20,905
Tin	29,601	30,703	27,416	28,816
Lead	147,145	178,907	35,824	43,992
Zinc	83,867	63,284	7,019	1,770
Quicksilver	1,220	946	306	303
Minor metals	5,997	3,435	17,221	13,252
Ores, etc.				
Tin concentrates	25,808	31,604	.....	.....
Pyrites	569,001	594,066	.....	.....

Copper imports include estimated contents of ore and matte. Exports include reëxports of foreign material.

Spanish Exports of Metals and Minerals, seven months ended July 31, as reported by "Revista Minera" in metric tons:

	Metals		Ores, etc.	
	1914	1915	1914	1915
Iron	11,502	84 071	4,467,837	2,599,185
Copper	14,851	11,100	74,975	26,304
Copper precipitate	6,481	7,216		
Lead	103 913	87 448	470	1,544
Zinc	990	2,172	60 866	17,059
Quicksilver	1,273	703		
Manganese			7,029	5,120
Pyrites			1,926,418	1,081,196
Salt			384 921	396,336

Imports of coal for the seven months were 971,706 tons, a decrease of 562,911 tons from 1914; imports of coke 117,789 tons, a decrease of 121,770 tons.

FOREIGN IRON

Foreign Iron Trade of Great Britain eight months ended Aug. 31 is valued by the Board of Trade returns as below:

	Exports	Imports	Excess
Iron and steel	£25,557,454	£6,501,686 Exp.	£19,055,768
Machinery, hardware, etc.	13,502,645	9,977 491 Exp.	9,525,154
Totals	£45,060,099	£16,479,177 Exp.	£28,580,922
Totals, 1914	68,287,516	19,871,738 Exp	48,415,778

Quantities of iron and steel exported were 2,954,263 long tons in 1914, and 2,087,676 in 1915; decrease, 866,587 tons. Quantities imported, 1,428,114 tons in 1914, and 766,319 in 1915; decrease, 661,795 tons.

Steel Production in Germany in July was 1,138,478 metric tons, being 57,692 tons more than in June. For the seven months ended July 31, the production was, in metric tons:

	Basic	Acid	Total
Converter	3,684,885	89,271	3,774,156
Open hearth	2,939,670	129,306	3,068,976
Direct castings	241,823	78,765	320,588
Crucible		58,265	58,265
Electric		61,964	61,964
Total	6,866,378	417,571	7,283,949

For the corresponding period in 1914 the total make was 11,015,676 tons, showing a decrease of 3,731,727 tons, or 33.9%, this year. In July there were 223 steel furnaces in operation.

Pig Iron Production in Germany in August was 1,050,610 metric tons, being 3,103 tons more than in July. For the eight months ended Aug. 31 the total was: Foundry iron, 1,587,913; forge iron, 200,739; steel pig, including all ferro-alloys, 1,073,673; bessemer pig, 117,463; Thomas or basic pig, 4,652,662; total, 7,632,450 metric tons, against 11,436,891 tons in 1914; showing a decrease of 3,804,351 tons, or 34.1%, this year.

IRON ORE

Shipments of Lake Superior iron ore continue heavy, and October is expected to show a heavy tonnage. Talk about prices for next season continues, but nothing definite has been done.

COKE

Coke production in the Connellsville region for the week is reported by the "Courier" at 417,724 short tons; shipments, 418,082 tons. This is the largest production for over two years. Shipments of Greensburg and Upper Connellsville districts, 40,055 tons.

Connellsville—Last Thursday's market for spot furnace coke was quotable at not over $1.90. Friday morning bids were made of $2.25 without bringing out enough coke and Saturday $2.40 was paid, this price being rather freely bid yesterday and today. The demand for prompt seems to be chiefly because the Republic Iron and Steel Co. has closed its Connellsville beehive ovens, in order to ship the coal to the battery of 75 additional byproduct ovens at Youngstown, to be put in operation early next month and giving, with the present 66 ovens, enough byproduct coke for all the company's blast furnaces. Meanwhile the company is a large buyer of prompt coke. Pickands, Mather & Co. have bought furnace coke for the first four months of next year for one of their Toledo stacks, and a six months' supply for Perry at Erie and Ella at West Middlesex, while there is still to be bought a three-months' supply for the other Toledo stack, coke being required for Toledo only until the byproduct plant being built at that point is completed. The total tonnage bought and still to be bought is about 45,000 tons a month. Contracts placed on this movement now amount to between 175,000 and 200,000 tons a month, chiefly at about $2.25 if for the year and at $2.35 if for the six months. These prices have been shaded in some instances but with the advance in spot coke operators are now expecting higher prices. Foundry coke has stiffened and is quotable at $2.60@2.75 for prompt and $2.60@2.85 for contract.

Chemicals

NEW YORK—Oct. 20

The general markets show little or no change from recent weeks.

Arsenic—There is no special change in the market and demand is only moderate. Quotations are $3.50 per 100 lb. for large lots and up to $4 per 100 lb. for smaller orders.

Copper Sulphate—About the usual business is forward and prices are steady. The quotation is lower at $6.50 per 100 lb. for carload lots, and $6.75 per 100 lb. for smaller orders.

Nitrate of Soda—There is little change. Demand is fair for the season and quotations are steady. They are held about 3.45c per lb. for both spot and futures.

Pyrites—Imports at Baltimore for the week included 2,862 tons pyrites from Pomaron, Spain.

Potash Salts—It is stated that experiments on the treatment of Utah alunite at one of the plants of the United States Smelting Co. have resulted in the production commercially of 18 to 20 tons daily of potash sulphate. The residue is an almost pure alumina. The Armour Fertilizer Co., it is said, has contracted to take all the potash salt that can be supplied.

Imports of refined potash salts into the United States for the eight months ended Aug. 31 are reported by the Department of Commerce as follows, in pounds:

	1914	1915	Changes
Carbonate	13,035,605	8,940,608	D. 4,094,997
Hydrate	5,081,483	2,028,142	D. 3,053,341
Nitrate	2,229,856	14,855	D. 2,215,001
Cyanide	318,087	862,127	I. 544,040
Other potash salts	4,067,764	2,075,741	D. 1,992,023

Imports of crude salts used mainly as fertilizers were as follows for the eight months, in long tons:

	1914	1915	Changes
Kainit	317,205	6,646	D. 310,559
Manure salts	150,973	13,647	D. 137,326
Sulphate of potash	30,696	10,627	D. 20,069
Muriate of potash	151,395	56,800	D. 94,595

The decreases, of course, are due to the stoppage of exports from Germany by the War.

Winter Mining at Fairbanks

By Hubert I. Ellis*

SYNOPSIS—Surface operations form the principal field for differences between summer and winter operations, but underground there are a few differences. Steam pipes have to be carefully wrapped to guard against excessive condensation, and pumps have to be carefully handled. Dumps are thawed by means of long sweaters, forced into the material. Sluicing methods are described in detail.

Although winter mining at Fairbanks, Alaska, differs from summer operation chiefly in the methods employed at surface, there are also important differences in the procedure underground. As a rule, winter mining is on a less elaborate scale and less time and expense are taken in opening up, or developing, the body of pay. The area to be stoped is smaller, most winter dumps mined in recent years consisting of gravel from pillars and other isolated blocks not large enough to justify the heavy development expense necessary for summer work. Since all the gold in the gravel is locked up in the dump until water runs in the spring and most operators have a limited bank account, it is not the usual practice to employ more men than is absolutely necessary, many mines being worked by four or five men on a cooperative basis, with perhaps as many more wage-workers during part of the winter. Another thing militating against extensive winter mining—by which is meant the storage of pay gravel at surface as distinct from prospecting and development—is the fact that it takes nearly all winter to find the pay and open it up on a large scale for summer work.

FIG. 1. SLUICING GRAVEL AT THE ALASKA FIELDS, HAND METHOD OF MOVING THE MATERIAL

Plan of Operations for Winter Work

The shaft is sunk in the usual manner, but is rarely timbered except that a light square-set may be inserted at the station. To avoid the cold as far as possible, it is a good idea to place the sump and pump a short distance from the shaft, but this frequently is not done. Drifts are usually short, rarely extending more than 100 ft. from the shaft, and less pains are taken to keep the working faces regular and of as great extent as possible. The cold air from the surface is sufficient to overcome the heat of the steam line and points for a considerable distance from the shaft, and it is often possible to work without timbering the drifts. On account of decreased sloughing and the smaller area of roof exposed for slabs to form, it is likewise easier to start stoping at the shaft, leaving a suitable pillar to be robbed later, and to work

*Kellogg, Idaho.

outward in all directions. Transport underground, owing to the small scale of operations, is usually by wheelbarrow.

Steam pipes must be wrapped or otherwise insulated to guard against excessive loss from condensation, and great care is essential to keep water from freezing in the pipes and bursting them. The pump, too, should be handled with care; it is sure to be refractory on a cold morning—and all mornings are cold in winter—and to require thorough warming with steam before it can be induced to start.

In the fall, before snow has fallen in any quantity, the site for the dump must be prepared at surface. If an old tailing pile happens to be in just the right place, it makes an excellent foundation; otherwise the brush and moss must be removed over an area as large as the dump is expected to occupy. The gin-pole is placed a little back from the center of this circle to make the bucket dump in the center. To avoid unnecessary rehandling of the gravel in sluicing, it is dumped over the sluice boxes, which are placed as near the ground as possible. If there is sufficient grade they are sometimes set in shallow trenches, which are easily dug in the brittle surface muck. Sometimes, however, the boxes must be raised several feet from the ground, in which case they are

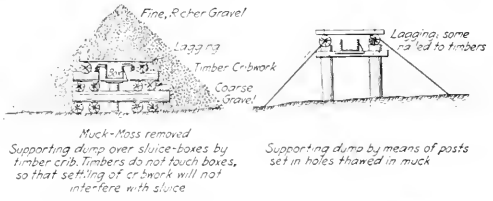

FIG. 2. THE GRAVEL PILE

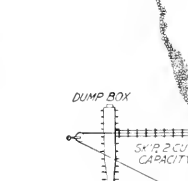

FIG. 4. THE DUMP SUPPORT

protected by a cribwork of logs with removable top lagging, as shown in Fig. 2. Two or three sets, or strings, of these boxes are used in order that the gravel may be sluiced with the smallest possible amount of work. It is not customary to place riffles in those boxes immediately under the dump, but to use the so-called "false-bottom" boxes, which are merely sluice boxes with 1-in. boards to protect the bottoms, and which may be set with a grade of 6 or 7 in. or less to the box length where 9- or 10-in. grade is required for riffled boxes. Since there is almost always an abundance of water while the winter accumulation of snow is thawing, the sluice boxes themselves will run with less grade than usual; they are not ordinarily placed in position, however, until spring. Short ditches anywhere along the hillsides will usually collect all the water required, and these are best excavated in the fall before snow begins to fall; in fact, that is regarded as the best time for all ditch construction. The ditches to collect water for sluicing a winter dump need not be large, since they usually have such grade that they are able to cut their own channels through the muck.

Classification Resulting in Building a Dump

As hoisting proceeds the dump piles up as a large cone. The biggest rocks roll farthest when the bucket dumps and collect at the bottom in a constantly expanding ring. Consequently there is a rude sort of classification, the bottom of the dump being composed of coarser, lower-grade material than the rest and the richest part being at the apex and directly below it. For this reason and for the additional reason that the bottom is generally below the boxes and requires elevating before it can be sluiced, the lower 2 or 3 ft. of the dump is often left if it does not show good values by panning, only the richer portion being sent through the boxes.

One disadvantage of the winter dump is that it must be thawed again in the spring. The sun would of course thaw it in time, but this would take so long that, aside from the matter of the loss of time, there would be no water for sluicing. Thawing is usually done by means of long "sweaters" of ¼- or ⅜-in. pipe, which are easily driven into the loose, poorly compacted material with light wooden mallets. Sometimes a sweater strikes a rock and has to be withdrawn, but it does not take long to insert it again. Each successive addition having frozen before it had a chance to settle and considerable snow

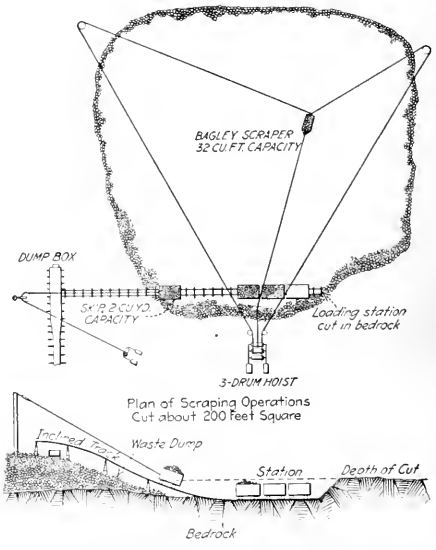

FIG. 3. DIAGRAM OF TYPICAL SCRAPING AND LOADING OPERATIONS

having fallen and been included in the dump, there is naturally a large proportion of voids; hence, when the dump thaws, it slumps heavily and loses its regular conical outline.

In sluicing, the lagging over the boxes is removed, one piece at a time, by means of a sharp pick and the gravel is allowed to fall into the boxes just rapidly enough to keep from clogging them. This work always starts at the lower end of the dump, since the boxes might otherwise clog underneath, where it is difficult to open them. All the gravel that will fall in having been sluiced, as much more as convenient is raked in by picks or pushed in by shovels.

When it becomes impossible to take further direct advantage of the force of gravity, there are several alternatives, among which the operator may choose. One of these is to drive into the boxes by hydraulicking with a small pump and suitable nozzle as much as possible of what gravel is left; this is probably cheapest for large dumps.

Another is to shovel the material into the boxes, using wheelbarrows for the final stages if they are of any advantage. If the boxes are set nearly flush with the ground, it may be feasible to use a horse or power scraper for the lower portion of the dump.

Disposal of the Washed Tailings

Since the boxes are always set as near as possible to the ground, there is rarely room for the free discharge of tailings. A place may be prepared for them in the fall by ground-sluicing away some of the muck, but this is not often done and is rarely adequate. In most cases the tailings require handling by some method or other. If the ground slopes fairly steeply and the dump is not large, room may be obtained by keeping a man constantly at work in the tailings, since he can spread the gravel rethawed and rehandled, involving great expense aside from loss of time; and the tailings must also be rehandled, making the third time for much of the gravel.

Winter mining is especially adapted to coöperative work on small isolated blocks or pillars, to narrow and irregular paystreaks, and to those creeks where it is difficult or impossible to obtain an adequate and dependable supply of water in summer.

It may be noted, in reference to winter mining, that some operators have been able to continue sluicing till December or later by returning the sluice water to be used again and again. The exhaust of the pumping engine, if turned into the discharge of the pump, helps materially to keep the water from freezing. A small amount of fresh water must be obtainable from a creek or ditch, however, to replace the inevitable loss. This

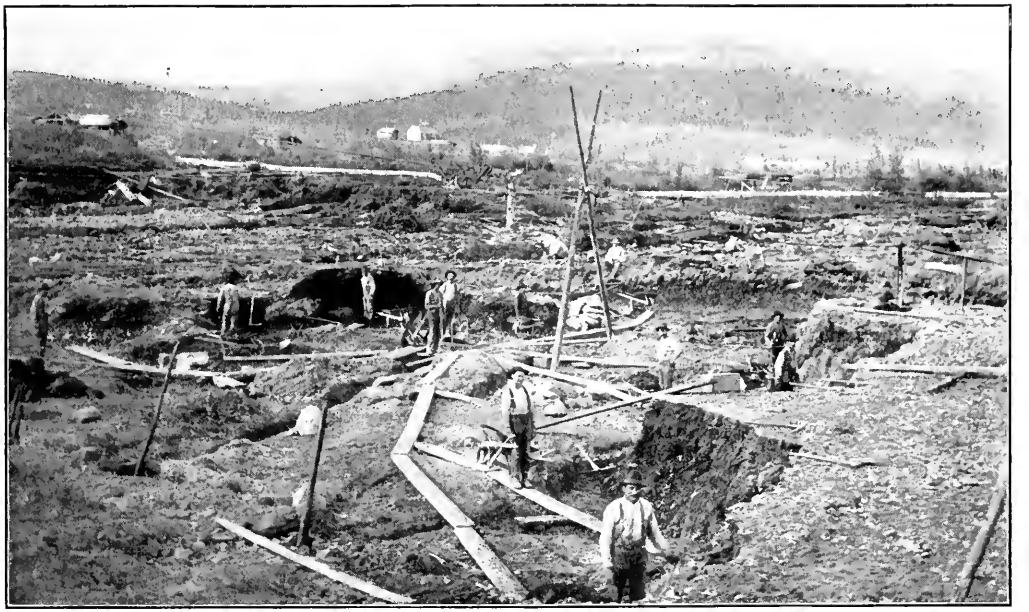

FIG. 5. OLD METHOD OF WORKING OPENCUTS, USING WHEELBARROWS TO DUMP INTO CARRIER BUCKET

out over a large area by simply pushing it around with a shovel while the sluice-head of water is running and by adding new boxes from time to time. Where the tailings problem is more serious, horse scrapers or small power scrapers are sometimes used with excellent results.

The chief advantages of winter mining are the following: Less cost for shaft, since it does not need to be timbered and may therefore be smaller; smaller cost of driving tunnels, for the same reasons; greater ease of obtaining fuel, machinery and other supplies while snow is on the ground; and the possibility of obtaining gravity water for sluicing at small expense on some claims where it is impossible to obtain it at all during the dry season. The disadvantages, compared with summer operation, are: The gold is not immediately available and it is difficult to form accurate estimate of the tenor of gravel; much time is taken to sluice the dump in the spring, which is in addition to the time required for mining and sluicing the same gravel in summer; the dump must be method is not suitable for general adoption, and it is probable that the muddy water greatly increases the loss of fine gold.

Opencut Mining and Its Variations

Owing to the depth to bedrock on most creeks, opencut mining did not attain any great importance in the Fairbanks district until the power scraper was introduced. Except for Fairbanks Creek, and upper Goldstream and its tributaries, the only ground suitable for surface work is at the extreme heads of the creeks, where paystreaks are narrow, irregular and generally low-grade. Some of this ground was mined in the early days, and a little is still mined by shoveling directly into the boxes. The gradient of the creeks is so low that it is necessary to place the boxes as high as possible, naturally increasing the difficulty and expense of shoveling, to avoid undue trouble with tailings; and in some cases the pay has been hoisted by windlass or the tailings removed by horse

scrapers. These narrow, shallow paystreaks are usually in the creek bottoms, and excess water during wet weather is likely to cause considerable trouble unless a large drain is dug on bedrock to keep the cut dry. It is necessary, near the heads of the creeks, to store the water in dams during dry weather, and even then it may not be possible to operate at capacity.

If the depth to bedrock is more than 6 or 8 ft. it is obviously necessary to elevate the gravel by some means; and if the paystreak is more than 20 ft. wide the gravel must be conveyed to the boxes or the boxes must be moved from side to side. The wide, shallow deposits of Goldstream and its tributaries were the first to be worked on an extensive scale by opencut methods, and the operators here hit on the scheme of combining drift mining and opencut mining by using buckets and automatic carriers in conjunction with wheelbarrows. The buckets dropped into sumps cut in bedrock and were filled from wheelbarrows; they were then hoisted up the inclined trolley-cables and dumped into the mud-boxes. Except for the smaller amount of development work required, less expense for thawing and the greater convenience of working in the open air, this process had little advantage over drift mining. Cost of digging bedrock drains or pumping out rain and seepage water, cost of removing overburden, delay when waiting for ground to thaw in spring or cost of thawing in order to expedite operations, and less efficient work of laborers hampered by rain, sun and mosquitoes—all these tended to place total costs more nearly on a par with those in drift mining.

The next step in advance in opencut work involved the use of small slip scrapers drawn by horses. On account of the high cost of equine power in a region where all feed must be transported thousands of miles at great expense, this method was important chiefly in that it paved the way for the power scraper. Double-drum engines succeeded the horse as the source of power; the main drum served to drag the loaded bucket forward while the other took the empty back. The drums operated by friction and reverse gearing, so that when the main drum was pulling the other was free to revolve in its bearings, and *vice versa*. By shifting the tail-block the scraper could be made to dig at different points in the cut. Holding the handles of a light scraper attached to the drum of a powerful engine was something worse than attempting to master a bucking horse, or so the workmen complained, and a substitute scraper, less dangerous to life and limb and at the same time capable of taking a larger load, was sought.

The Scraper and Methods of Using

In recent years the slip scraper has dropped from use and its place has been taken by the Bagley scraper of the bottomless or of the wheel type. These scrapers are operated by double-cylinder three-drum hoists, of which 15 were working in the Fairbanks district in 1911. Thirteen were on Goldstream and its tributary, Pedro Creek, one was on Fairbanks and one on Cleary. The smallest had 7x10-in. cylinders, the largest 10x12. Twelve were "Americans," made by the American Hoist and Derrick Co., of St. Louis, and three were made by the Washington Iron Works, of Seattle.

The usual practice is to have the dump box and sluice boxes at one end or side of the cut, on a timber trestle at sufficient elevation to discharge the tailings freely. The Bagley scraper, having obtained its load, is dragged up an inclined approach to the dump box, where it discharges automatically, the teeth engaging a timber and causing the scraper to turn bottom up. By means of two tail lines and suitable leads, as shown in Fig. 3, the scraper can be dragged back to any desired position in the cut. The overburden of muck is usually removed by "ground-sluicing" and the barren gravel is scraped into a pile at one side if there is room. The pay-gravel and as much of bedrock as carries gold, unless it is too difficult to move, are then scraped into the boxes. Details of operating vary, of course, at different mines, but a brief description of the more important features of a typical mine will illustrate the practice.

The ground was about 16 ft. deep, with 13 to 14 ft. of overburden and 3 or 4 ft. of pay. The upper 6 ft. of the deposit, being muck, was removed by ground-sluicing. The rest of the waste was scraped out, and owing to lack of a site for storage much of it was sluiced at considerable expense. The creek was diverted and carried past the cut on the left limit, the pay being chiefly on the right limit. This was not a difficult operation; the new channel was merely started in the muck and the creek was forced to do most of its own cutting. The area covered by the cut was about 40,000 sq.ft., about half of a normal season's work. The engine was of the ordinary three-drum type with 8x10-in. cylinders, and the scraper had a capacity of 32 cu.ft. The scraper dumped into a car set in a station cut in bedrock; the car held 2 cu.yd. and was of the skip pattern. It was raised on an inclined track to the dump box by means of a separate engine. This was the first time a car was used in scraper mining at Fairbanks for elevating the gravel to the sluice boxes, but the saving in fuel was so great that the method will be widely copied.

After the waste had all been removed about 1,000 sq.ft. of bedrock was stripped a day when everything worked smoothly. The average crew consisted of 12 men for two 10-hr. shifts, except in cleaning bedrock, which was done by hand and required several extra men. Three cords of wood were burned per shift of 10 hr. at a cost, when delivered during the winter, of $10 per cord, ranging up to $14 when delivered in summer. The total operating cost per shift was about $89, divided as follows: Engineer, $9.50; fireman, $7.50; dump-box man, $7.50; three extra men at $6.50 each, $19.50; wear and tear on machinery and depreciation, $15; wood, $30. The recovery, stripping, 1,000 sq.ft. running 50c. per sq.ft., was about $500 a day. The cost of erecting plant, removing overburden, etc., is a large but variable item in scraper mining. At this particular mine it was nearly 35c. per sq.ft. last season, as against about 10c. for mining the pay itself. This was the first season's work, however, and many unforeseen difficulties arose, not the least of which were a very backward season and continued bad weather; it is hoped to get costs down to 25c. per sq.ft. in the near future, equivalent to 42c. per cu.yd., waste and all, or about 60c. per yard of gravel handled.

Cost of Instituting Operations in Gravel

Starting on a new claim and buying new machinery the total expense on such ground as that described, before sluicing of pay begins, is not far from $12,000. In order to win a profit the operator must have at least three or four years of work on material yielding 50c.

per sq.ft. of bedrock. Aside from labor, the largest single item entering into the cost is fuel, which may be $60 a day when two shifts are working, of a total operating cost of $188 a day. Cheaper power is of even greater importance here than in drift mining, and the continued prosperity of the industry depends on the construction of a central power plant or the importing of a cheaper fuel. Unlike drift mining, opencut mining by scrapers offers a growing market for electric power, for there are outside the Fairbanks district proper many shallow, low-grade deposits that can undoubtedly be worked at a good profit by this method. On many of these creeks the gravel is 6 to 10 ft. deep and there is very little muck overburden. Under present condition this can be mined for about 60c. per cu.yd. With cheaper power, cheaper labor and cheaper freight, all consequent on the construction of the government railway, this cost should easily be reduced to 40c. and can probably be cut to 30c.—about 10 or 12c. per sq.ft. of bedrock.

The matter of cost is always one of great interest. Unfortunately the operators at Fairbanks do not keep records that make it possible to determine detailed costs or even, in many cases, the total. It is therefore impossible to do more than make a rough guess, and this would place the average of the entire district at about 75c. per sq.ft. of bedrock, with a minimum of 50c. and a maximum of $1.25. The following figures, which are estimates of the cost of working a certain block of ground on Engineer Creek a year ago, may be of value as showing in a general way the weight of the principal items:

COST OF MINING OPERATIONS

Development	
Bunkhouses, messhouse, cost of setting up plant	$1,500
Shaft and station (90 ft. to bedrock)	2,500
Main drifts, 400 ft. at $4	1,600
Crosscuts, 200 ft. at $2.50	500
Incidentals	600
Total	$6,700
Cost per sq.ft. developed, at 40,000 sq ft	17c.
Mining	
16 shovelers, 2 carmen, 1 fireman, 2 extra men, at $5	$105
Engineer, blacksmith, pointman, at $7	21
Dump-box man	6
Board, at $2.25 per man per day	58
Fuel, 3 cords at $8	24
Wear and tear and depreciation on plant	10
Total operating cost per day	$224
16 shovelers, each stripping 35 sq ft per day, sq ft	556
Cost per sq.ft.	40c
Total cost, including development, per sq ft	57c

It may be noted that this ground is more easily worked than the average in the district, that fuel costs less, and that the points require less attention and less steam. Water for sluicing must be pumped, however, and must be returned during most of the summer. Owing to a desire to be on the safe side, in the absence of reliable figures for other mines, these costs should be slightly reduced in operation. Unfortunately, the ground passed into other hands and there was no opportunity to check the above estimates.

Duty Concerning Belt Repairs

By A. L. H. Street*

An experienced employee in a Missouri ore mill was injured while assisting in shortening a belt that operated a mineral pump, owing to his arm being drawn into the pulley, which was not stopped. A suit against his employer resulted in a judgment for $1,000 damages, but the St. Louis Court of Appeals recently reversed the award on the ground that negligence had not been established. (Chandler vs. St. Joseph Lead Co., 178 Southwestern Reporter, 217.) The view of the higher court is expressed in the following language:

> The master is not an insurer of the safety of the servant and, within the limits of ordinary prudence, may conduct his business in his own way. There is here no negligent order or command to the servant. No one directed plaintiff to repair this belt, but he did so of this own initiative, in a manner of his own choosing and without requesting anyone in authority to stop the machinery. . . . . An employee performing the duties assigned to plaintiff was expected by the defendant to make such repairs. But the evidence is that the task in which plaintiff was engaged when injured was one which could be safely performed if reasonable care was employed. And plaintiff, by reason of his long experience, possessed the requisite knowledge and skill for the proper performance thereof. The master may intrust to the servant the performance of the ordinary and simple duties incident to the servant's employment and resting upon the latter's knowledge and skill. And the master has the right to assume that the servant will exercise ordinary care in the performance of such duties.

*Attorney, Security Building, Minneapolis, Minn.

Stellite, a Cobalt-Chromium Alloy of Great Hardness

In a paper read before the annual meeting of the American Institute of Metals, Sept. 30, 1915, Elwood Haynes described some of the characteristics of stellite, a binary alloy consisting of cobalt and chromium, which was discovered by him and produced as early as 1899. Its principal property is a considerable hardness, since alloys containing 10% or more of chromium could not successfully be filed, but the file could slowly wear away the surface of the metal. It also has considerable toughness. Alloys containing as high as 25% chromium show an elongation of 10% or more. Its tensile strength and elastic limit are comparatively high, a bar of metal showing elastic limits of 85,000 lb. and a tensile strength of 110,000 lb. The color of the alloy lies between that of steel and silver. It is resistant to oxidation or other changes when exposed to either dry or moist atmosphere at all temperatures under a dull-red heat.

The combination has been used particularly as a cutting tool for steel and iron. Its virtue for such a purpose lies in its ability to maintain its cutting edge at a high rate of speed at temperatures which would immediately cause the failure of any known tools containing any notable quantity of iron. Owing to the fact that it retains its hardness even at a full-red heat, it cannot be forged.

Stellite can only be reduced to a desired form by casting it in dies in the form of bars which are afterward ground to a cutting edge. It was recently ascertained that a ⅜x2½-in. piece of stellite ground to the form of a grooving tool cut 14,000 grooves in cast-iron pistons ranging from 3½ to 4⅜ in. in diameter before it became too much worn for further use. This work was done in regular practice and not as a test. A stellite tool of the same dimensions, but which was ground to round-nose form and used for turning pistons, turned off more than 8,500 lb. of cast iron before becoming too short for use. Considering only the portion of the tool that was actually ground away, the tool turned off 1,000 times its weight of cast iron before becoming too short for service.

There are combinations made for turning steel and others for turning cast iron. Those for turning steel are now being used extensively for making shrapnel shells at high speed.

Potassium Salts: An Economic Geological Study--II

By E. Mackay Heriot*

SYNOPSIS—In continuation, the characteristics of the Stassfurt and Hannover deposits are discussed, also the Alsatian deposits. The probability of the discovery of new deposits is examined and explained.

I am going to divide the German potassium deposits into two types: The Stassfurt and the Hannover, for there is a considerable difference between them.

In the Stassfurt type the upper Permian contains from 20 to 30 m. of massive red clay with anhydrite balls and some rock salt, then from 0.3 to 3 m. anhydrite. The following Permian contains 50 m. rock salt; 1.5 m. anhydrite with rock-salt crystals; 5.15 m. red massive clay with anhydrite balls and rock salt; 100 to 150 m. younger rock salt; 40 to 50 to 90 m. main anhydrite; 4 to 10 gray salt clay; 30 to 40 m. carnallite region; 20 to 40 m. kieserite region; 40 to 60 m. polyhalite region and 300 to 500 m. older rock salt (anhydrite region). The middle Permian contains 70 to 100 m. older anhydrite with inclosed layers of bituminous dolomite slate, so-called "stinkslate," and with one or two salt beds of from 10 to 15 m. The lower Permian contains 4 to 10 m. Permian limestone; 0.5 to 4 m. copper shales; and Permian conglomerate. The copper shales referred to are those of the celebrated Mansfeld copper mines.

In the Hannover type of deposit the upper Permian contains up to 250 m. rock salt, with at about 50 m. a small potassium layer; 30 m. younger main potash bed; 20 to 40 m. rock salt, sometimes with a small potassium layer; up to 1 m. intermediate anhydrite; 5 m. red massive clay; 30 to 50 m. younger rock salt; 40 m. main anhydrite; 4 to 5 m. gray salt clay; 3 to 30 m. older potash bed; up to 60 m. of kieserite region and some older rock salt.

The middle Permian has older anhydrite with layers of bituminous stinkstone.

The Stassfurt type is well-known and has been carefully studied, but the Hannover type has not. It has a confused build, which makes a clear study all the more difficult.

First and foremost, the absence, in many localities, of the gray salt clay and main anhydrite layer is unfavorable. Only here and there mixed pieces show its presence. It will be remembered that when I described how these formations originated, I said that after the potassium salts had been precipitated, the salt clay was formed. This salt clay has been the preserver of the easily soluble potash salts, and its absence in the Hannover mines gives rise to unfavorable ideas.

The thickness of the older rock salt is not yet known in the Hannover type. A kieserite and polyhalite region, as found in Stassfurt, is not met with here. Then again there are no potassium salts in the younger rock salt. At Stassfurt we find the older rock salt marked with year-rings, and in the Hannover the younger rock salt is well marked with year-rings of anhydrite. In the Hannover mines one finds also rock salt, sylvine and carnallite in fissure veins.

*Mining engineer, Rio Tinto, Huelva, Spain.

As examples of the Stassfurt type I give sections of the Stassfurt-Leopoldshall mines,[1] Solwayhall, near Bernburg and Vienenburg im Harz. In the former, one sees the Trias formation covering the Permian is made up, from top to bottom, of gypsum, salt-clay carnallite region, kieserite region, polyhalite region, and last the older rock salt or so-called anhydrite region. In Solwayhall it is nearly the same, except that the younger rock salt fails at certain points, and hartsalt is found above the carnallite. The anhydrite has not changed to gypsum as is the case at Stassfurt. At Vienenburg the succession is normal, only the carnallite has been partly altered to sylvine.

Of the Hannover type I give Wilhelmshall am Huy.[2] We see a large mass of older rock salt, limited on one side by sylvine, carnallite, salt clay and anhydrite and on the other side by carnallite, salt clay and anhydrite. At the top the kainite forms a cap on the carnallite. The younger rock salt is considered as a secondary mineral, having been deposited by solutions which received their salt from other salt formations. Carnallite, the best-known of the potassium minerals, is the originator of most of the other secondary minerals such as sylvine, kainite, sylvinite, etc. It must be accepted that only a small part of the potassium minerals are of primary origin. On the other hand, most of the primary salts occur as secondary minerals. At certain localities the secondary minerals form the chief mass and the primary minerals are only present in small quantities. The accompanying table by Lowe shows the occurrence of primary and secondary minerals:

OCCURRENCE OF MINERALS

Without Exception	Chiefly	Seldom
Anhydrite	Primary	Primary
Gypsum	Rock salt	Sylvine
Salt clay	Polyhalite	Kainite
Douglasite	Kieserite	Schonit
Boracite	Carnallite	Langbeinite
Hydroboracite		
Sulphoborite		

I must leave the Permian era for a time, and will now show salt layers in other geological formations. The most important, next to the Permian occurrences, is the new find in Alsace, near the French border. Borings at Niederbruck in Upper Alsace tapped the upper layer of potash salts 154 m. thick at a depth of 358 m. The lower salt-bearing stratum had a total thickness of 327 m. and was cut at 620 m. Many borings have cut the salt formation, and a large area has been proved.

In 1913 shipments began from Alsace and reached over 500,000 tons. The salts were really discovered when boring for oil. In 1909 the first shaft was finished. Over a dozen mines are now at work. They represent 4% of the total German output. Up to the present the salts seem to underlie about 7 sq.mi.

The Alsatian Potash Deposits

From a geological point of view the Alsace occurrence is similar to that of Kalusz (Austria), which I shall describe later on, and very different from that of Stassfurt. The Alsace deposit occurs in the Oligocene. A boring at

[1] See "Eng. and Min. Journ.," Oct. 23, 1915, p. 670, for the geological section.

[2] Ibid., page 671.

Wittelsbach was put down to 1,119 m., and from 0 to 358 m. the ground traversed was gravel and marl; from 358 to 512 m., salt marl; after 358 m., 3 beds of rock salt and anhydrite, and at 473 m. a 5-m. bed of potash salts. Then came various beds of rock salt, anhydrite and dolomite, then a hundred meters of greenish-gray marl schist. There seems to be a marked absence of carnallite and chloride of magnesia. The question is, Does the Alsace basin cross over into France?

Potash salts have been found near Salzgitter in Germany. I give a sketch of this occurrence which pertains to the Triassic era.[3] The salt is 280 m. thick and contains carnallite and kieserite. Fossils of the Rot have been met with and prove a sea deposition.

The salt deposits of Bochnia and Wieliczka lie along the slopes of the Carpathian range of mountains. No potash salts have as yet been found here, but otherwise the geology is exceedingly interesting and I give a section of the Wieliczka mine.[4] The local strata are divided into two epochs, a younger and an older. The former is composed of sand and clay with gypsum, and pertains to the upper Miocene with *ostrea digitalina* and *cerithium lignitarum*.

The older formation is the rock-salt series. In Wieliczka the salt lies directly under the gypsum clay. It is quite clear that the salt is of lower Miocene age. The deposit is 3½ km. by 0.8 km. and about 150 m. in depth.

Beginning at the top is the salt clay, then salt sandstone, clay, anhydrite and rock salt. The rock salt is classified as Spiza salt, of fine crystalline structure; Szybiker salt, which is coarse-grained; and green salt, which is also coarse-grained and of a greenish color.

Fossils and Salt Deposits

Within the stratified salt region fossils are found, more especially in the Spiza salt, where one may say they never fail and often occur in great masses. The fauna, with the exception of a *planorbis art*, are sea dwellers and are classified into 68 species. This is interesting because in all the great German potash deposits not a single fossil has been found, and yet there is no doubt as to the origin of these salt beds. It is, however, by no means easy to explain the lack of fossils.

Will potash salts ever be found in the neighborhood of Bochnia and Wieliczka? I have found it necessary to introduce a small map of the Carpathians in order to show the positions of Bochnia, Wieliczka and Kalusz.[5] All three lie on the north slope of the Carpathians. At Kalusz, potash-salt deposits have been encountered and are being worked. The age is also lower Miocene. Kalusz lies 26 km. NE of the mountain range. The salt-bearing formation dips SW 30, 40 or 50°. There is a lower salt clay without potash salts and an upper salt clay carrying potash salts. The lower salt clay consists of thin layers of clay and salt and carries about 50% of rock salt. It has a thickness of 90 m. and has not been pierced. The upper salt clay is about 40 m. thick. In this is found a bed of kainite. Anhydrite, gypsum, carnallite and picromerite are also met with in small quantities. Above the salt clay follow gypsum and clay. The kainite is from 8 to 12 m. thick and is generally covered with anhydrite. The production of potash salts, which is about 1,000 tons annually, is not exported, but consumed at home.

[3] "Eng. and Min. Journ.," Oct. 23, 1915, p. 670.
[4] Ibid., page 671.
[5] Ibid., page 669.

The latest find of potash salts is in Spain. Carnallite has been cut while boring for rock salt at the Cardona mine, near the borders of the Barcelona-Lerida provinces. The salt is in the Miocene formation. Nothing definite is known to the public as yet in regard to the commercial value of the Spanish potash, but the government has sent geologists to make a report. In the meantime the German potash syndicate has acquired large interests.

The salt beds of the Saltrange, in the Punjab, India, are of Cambrian age, and those of Cheshire, England, of Triassic. Thus we see that potash and rock-salt formations are not peculiar to any one geological period.

Probability of New Deposits

What are the prospects of finding new deposits of potash salts? They are certainly favorable. Let us look back to a few facts already recorded. Potash beds have been encountered in Prussia in the Permian formation; near Salzgitter, Germany, in the Triassic; at Kalusz in Austria and Alsace in Germany, in the Tertiary formation. The Prussian Permian and the Tertiary occurrences at Alsace and Kalusz were doubtless formed by deposition from sea water. Thus we find that the Permian era holds no monopoly of potash salts, as was formerly believed to be the case. The Alsace find is the most striking contradiction.

It only needs certain natural conditions to form a potash deposit. First there must be a salt-water basin in which more water is evaporated than enters; and second, the potash salts which are deposited must have a waterproof covering, such as anhydrite or, better still, salt clay. Whether the basin is in intermittent connection with the ocean—the bar theory—has nothing to do with the question in general. Today one can observe the process of salt deposition in the Caspian Sea. This body of water is an inland salt sea, and its bottom is already covered with rock salt. The potash salts being more soluble, are still held in solution.

It is not likely that the German Permian sea is the only large one of its kind among the many periods of the earth's formation. There are most likely many more. Why then have such depositions not been found more often? This question is easy to answer—they have not been looked for. The Spanish potash salts were met with by accident when testing the thickness of the rock-salt bed. The Alsace potassium was found casually while boring for oil. Another such mere chance found the Kalusz salts. The Anhalt mines, the first German salt mines, were worked for their rock salt. Later, Precht discovered the value of potash salts as a manure. This gave rise to the opening up of the salts of the North German plain, the potash salts of the Permian Sea.

That the German potash syndicate, which controls the output of the German salts, is well aware that potash may eventually be found outside Germany is seen by its hurried interest in the Spanish field. Up to the present, potash salts of marine deposition, other than the German Permian, have been discovered by accident. Wherever such a find has taken place, many competitors have rushed to the scene of action and often availed themselves of a good opportunity. It would seem to me that any company laying out a considerable amount of money to discover these salts should be given a certain monopoly, or say a large area to work upon, if it were so lucky as to find them. Such a company would have to examine thor-

oughly the territory under which salt formations are supposed to exist; at the start superficially, after which drilling operations would commence.

I hardly think that a study of the relation of land to water in the different geological ages will help much. I have given, however, a sketch[6] of the German Permian Sea, connected, as it seems to be in Russia, with the ocean. On the same map will be seen the Mediterranean Sea, which is about the same size. If we look at the map of Germany, we see that the salt area extends to Hamburg on the north, to Inowratzlow on the east, to Münster on the west, and to Alsace on the south; and no one as yet knows the real boundaries of these huge salt areas.

To the west, borings were being carried out in France, near Belfort, on the chance of the continuation of the Alsace field. The map shows that potash always occurs with the rock salt, but that the former covers only a small portion of the latter. This, of course, is natural, although where rock salt is found it is by no means certain that potash salts will be present, and boring is the only way to find out where they do exist. Potash is not likely to appear in salt springs, because if it did, it would indicate that water had entry to the potash beds and they would soon cease to exist.

How Prospecting Should Be Done

The rock salt must be pierced, and then, as a result of careful observation and expenditure of sufficient capital, potash salts may also be cut. The German potash was found at considerable depths, varying from 300 to 600 m. A borehole of this depth is an expensive undertaking. It would cost about $10,000. The prospecting of a small area of country would necessitate say 10 holes and cost more than 10 times this amount. A suitable spot for the first hole would have to be found, and this might entail much pioneer work. When the likely spot was located, a contract could be made for a hole with a guarantee of, say, 600 m. depth. The class of ground and local conditions would settle the price per meter and the size of the hole at the surface. The boring should be rotary, as every meter of core must be examined. Even if the result were negative as regards salt, it would add more knowledge with reference to hole No. 2.

A mining engineer with considerable experience in potash-salt prospecting should be placed in charge and the advice of local geologists taken advantage of; but the engineer should be allowed to determine the position of the holes. Those who have spent several years at this work will understand what this means. In Germany during the potash boom geologists sprang up in many corners; even chemists who had no knowledge of geology drove up to the boreholes and gave their opinions of the cores. In many cases the engineer who was most competent was not asked to give an opinion. In those days boring syndicates were formed overnight, perhaps by needy gentlemen after a good dinner.

A representative drove out to see the landowners, who in Hannover have the mineral rights. The landowners were generously treated to beer and schnapps, and when they had had considerably more than was good for them, a contract was agreed to. Today this matter is not so easy. Chance sometimes brought luck and the value of shares would rise from a few dollars up to $700 in one night; but there were plenty of failures.

In Prussia he who bored the rock salt first had a right to the potash salts also. Therefore in Prussia boring was carried out in competition. The writer has taken part in many interesting borings both in Prussia and Hannover. A sketch of the ground pierced by one of these borings I superintend in the Eichsfeld basin is given.[7] No one thought that the potash salts discovered in the plains would continue under the Muschelkalk Mountains. It will be seen, however, that these are mountains made by erosion and that the stratification lies concordant with the underlying strata. Thus it needed only some geology applied to mining, and I give this example for that reason. Again, look at the section of Wilhelmshall am Huy. If the hole was sunk on the left-hand side, an immense amount of kainite and carnallite would have been indicated, and as it is a question whether the dip could have been observed, it might have been taken for the width of the layer.

The engineer anyway would have to report the length of the potash cores. Subsequent mining would prove that the stratification was "on end." This is often the case in the Hannover type. If the drill had passed only a little more to the left, no potash salts would have been found.

As a detail of boring, care must be taken to use magnesium chloride instead of water when in the salt region. Water leaches out the rock salt, but it would in a short time completely dissolve the potash cores before they reached surface.

Boreholes Must Be Carefully Refilled

It takes nearly as long to fill up a hole as it does to bore it, that is to say if it is done properly. In Germany this is a most important item and government engineers establish special regulations for the procedure and see that their orders are carried out. In the salt region the hole is filled with baked clay balls. A certain number are thrown in per minute and stamped at given intervals. This is done in order to safeguard the potash beds against the intrusion of water. All shafts sunk for this industry are circular in form and watertight. In Germany two shafts are obligatory for the safety of the men. I have described the methods of sinking these shafts in previous pages of the *Journal*, and there is nothing new to relate. The cost of a shaft under average conditions is about $150,000, but if much water or quicksand is encountered the cost may be much higher. One may say that this class of shaft sinking has reached a very high standard in Germany, thanks to the modern potash-salt industry.

In this article I have endeavored to show the importance of the potassium-salt industry, its main geological features and the chance of its extension in the future. I will now give some of the principal conclusions at which I have arrived:

1. As far as can be seen the only considerable source of potash is marine depositions in the form of beds of Tertiary or earlier age.

2. That the chance of finding such deposits is good provided prospecting and boring are carried out to great enough depths at suitable places. It is to be remembered that up to the present, potash salts, outside of known areas, have been found by chance.

3. That the present consumption of potash salts is only a small part of what the world really needs.

4. That on account of these facts governments should offer special facilities for prospecting.

Minerals of Asiatic Turkey

SYNOPSIS—Northern Asiatic Turkey contains a wide variety of minerals of economic value. Among the important resources of the region are copper, mercury, antimony, iron, manganese, chromium, coal, petroleum, borax, emery and meerschaum. These deposits have long been worked in primitive fashion, but political conditions have delayed modern exploitation. Some of these supplies, especially copper, are now badly needed by Germany, and feverish activity in certain mines would doubtless follow the cutting through of "the road to Turkey."

Should the Germans succeed in hewing a road through to Turkey, a mineral empire of the first magnitude will be opened up to the Teutons, one which contains some rich though little developed deposits of copper—a metal of prime importance to the Central Monarchies.

The mineral resources of northern Asiatic Turkey are important and varied, but these deposits have lain practically dormant for centuries, largely owing to the inability of anyone to exploit the deposits without being themselves exploited. The heavy government fees and the lack of transport facilities have also retarded the mineral development.

The copper resources, while not great in the sense of some modern mines, are of special importance to the Central Empires, which happen to be deficient in deposits of this indispensable war metal. The high grade of the Turkish copper deposits might permit of their being useful in case the present conflict becomes protracted, and in any event would be a valuable asset to the Teuton empires in future wars. The varied mineral deposits of the Turkish peninsula form one of the links in the chain of strategic resources that will be connected up by a Teutonic victory in the Balkans. It therefore seems likely that the Allies, even though they give up the Dardanelles project, will do their utmost in blocking "the road to Turkey."

The accompanying map, based on one by Leon Dominian, reveals to what a large extent mineralizing agencies have been at work in the peninsula of northern Asiatic Turkey. The process of ore deposition[1] appears to have been heaviest in the three zones of major folding which encircle the elevated barren plateaus of the interior. Metalliferous zones and mineral belts are fairly well outlined by the cartographic distribution.

The complex metalliferous regions of Anatolia[2], of the east Pontic range—extending from the coast inland between Unieh and Trebizond—and of the upper basin of the Tigris constitute fields that bear promise of interesting developments when results of detailed investigations become available.

MAP OF NORTHERN ASIATIC TURKEY, SHOWING DISTRIBUTION OF MINERALS—AFTER DOMINIAN, 1913

[1] Excerpts from "Cartographic Documents of Economic Geography," No. 2, 1913. Geographischer Kartenverlag Bern, Berne, Switzerland.

[2] The term "Anatolia" is employed here in the sense generally accorded to it by European writers, whereby it refers to the western section of Asia Minor. The Turkish name "Anadolu" is used, however, by the Turks and Turkish-speaking races to designate the entire peninsula.

within the peninsula throughout ancient times. In the heyday of the vanished kingdoms of Sumer and Akad, throughout the supremacy of the Babylonian Empire, as well as at the height of the Hittite and Mycenean powers, mining had assumed sufficient importance to have become the means of sustenance of the inhabitants of numerous settlements scattered between the Ægean coastland and the Persian Gulf. During Byzantine and Ottoman sway the art of working ores was also carried on profitably. From the Seventeenth Century to our day, however, the industry gradually declined. Some attempts have been made in the past decade to revive it; in a few instances, as at Balia in the western end of the peninsula, success has attended these endeavors. In general it should be noted that mining in recent years has been mainly confined to the districts lying close to the coast.

Coal Widely Distributed in Asia Minor

Coal is of widespread occurrence in Asia Minor. The northwestern projection of the peninsula forms part of a district wherein lignite deposits have been worked in a number of localities. The lignitic beds occur mostly in Tertiary lacustrine deposits and appear to belong to a zone of transition between the Miocene and the Pliocene. The southwestern coast of Asia Minor, with its hinterland, does not appear to be devoid of coal. In the Province of Smyrna, the Sokia and Nazili beds have been developed for local use. Coal was mined about half a century ago in the northern section of Mesopotamia, near Jesireh. Some work was also undertaken in the Hamrin mountains. The deposits near Mosul have not been worked. In the hills lying east of Kifri, the natives indulge in occasional desultory exploitation of this fuel. In Syria and the Lebanon a number of native exploitations are encountered. Some of these were undertaken to supply the small silk factories with fuel.

The best-developed Turkish coal field is found at Heraclea. The coal is bituminous and occurs in a belt about 60 km. in length. The coal beds outcrop near the coast. They overlie Carboniferous limestones and are in turn unconformably overlain by Cretaceous beds of great thickness. The output for 1912 from this field exceeded 700,000 metric tons. Occurrences of bituminous coals are also reported from the eastern section of the peninsula. The district between Lake Van and the Persian frontier appears to be favored in this respect. Anthracite has never been mined in Asia Minor, but its occurrence is reported from a number of localities.

Gold Mined by the Ancients

Little gold is produced at present, but the precious metal is known to occur at Serjiller, south of the Dardanelles. The abundance of gold jewelry found in the excavations on the site of the several cities of Troy indicates a large production from near-by localities. An ancient locality which was famed for its gold mines was Astyra, the site of which is now marked by mines that existed at the time of the explorations of the Greek geographer, Strabo.

The valleys of the Hermos and the Pactolus, in Anatolia, have been the site of ancient placer mines. How prolific in their yield of the precious metal the gravels of these rivers must have been may be inferred from the frequent allusions in ancient literature to the gold-bearing sands of the district, now known as the valley of the Gedis River. In recent times peasants living in the vicinity of Boz Dagh (Boz Mountain) make a scanty livelihood by washing the gravels brought down by the rivers.

The environs of Izpir in the east Pontic area contained gold fields that are known to have been worked from the Third Century B. C., to the end of the Seventeenth Century A. D. Throughout the Nineteenth Century small quantities of gold were mined intermittently around Bulgar Dagh. This region bids fair to become the site of future producers of gold, silver and lead.

The best-developed silver-lead mines are found near Balia, at a distance of about 100 km. from the sea. The ore occurs in a contact zone between Tertiary augite-andesite and Carboniferous limestone. The contact zone varies between 2 and 5 m. in width. The limestone at the contact is silicified but barren. In the andesite, on the other hand, are found accumulations of pure galena which seem to be connected with fissures parallel to the contact zone. The ores carry galena, blende and pyrite, and as formerly mined, contained on an average from 16 to 20% Pb and 8% Zn. The last operating company was the Société Anonyme Ottomane des Mines de Balia Karaidin. The 1913 production was valued at £171,000.

Copper Mines Along Black Sea Coast and in Upper Valley of the Tigris

The two most important copper belts in Asiatic Turkey occur in the eastern portion of the Black Sea coast, as far inland as the Pontic ranges, and around Argana (Arghanah) in the upper valley of the Tigris. Copper prospects have been noted as far west as the vicinity of the seaport of Sinop. The region around Espie, near Kerasund, is the center of a district noted for its mineral yield in antiquity. Here ancient workings abound and have been the site of small operations carried on intermittently in the last 20 years.

The celebrated Argana mines, from all accounts, contain high-grade ore. These deposits are known to have been exploited since 1096 A. D. within an area of about 12 km. square. In recent years mining has been carried on by the Turkish government, both on a leasing system and by direct management. The ore is broken to nut size and undergoes successive roasting until a product containing about 30% Cu is obtained. In this form the product is transported on camels to Black Sea or Mediterranean harbors. The cost of mining and treatment at Argana is estimated at less than 3c. per lb. The disturbances of the last three or four years have caused cessation of work throughout Turkey, although it is possible that exploitation has been resumed recently under German management. The production cannot be of great importance immediately, however, as the organization of operations will require time in order to be productive in a large sense.

Mercury, Manganese, Antimony and Chrome Ores Occur in Important Quantities

Two deposits of cinnabar were working in 1913. The Karaburmu mines, situated about 30 km. from the town of Smyrna, produce about 3,000 flasks of quicksilver annually. The deposit lies in the vicinity of basaltic flows and consists of metamorphic siliceous schists impregnated with cinnabar. Mining is done entirely in opencuts on ores containing as little as 0.25% Hg. The

cinnabar appears to be concentrated in the fines, and the ore is accordingly screened. The screenings assay from 0.75 to 2% Hg. The plant at the mine comprised two double Spirek tower furnaces for broken ore and a Cermak-Spirek furnace for fines. This installation had a capacity of 30 tons per day. The other mercury deposit occurs in the vicinity of Konia. Here the ore is found in veinlets, nodules and small particles in a crystalline limestone close to schist, at no great distance from old eruptives. The mineral appears to be present whenever the limestone becomes silicified. Some stibnite is associated with the cinnabar.

Pyrolusite is mined from the Phlinika district, much of the ore produced assaying 52% Mn. At the Zengan mines, high-grade manganese ore is obtained. Manganese ore is also known to occur near the Russian frontier in the eastern Pontic area.

The two important centers of antimony production are Odemich and Jinlikaya. Ore carrying as much as 65% antimony is found in both. At Jinlikaya the veins cut through crystalline schists. Shipments were formerly made chiefly to England by way of Smyrna.

Asia Minor has contributed largely to the world's supply of chrome ore. The Turkish ores are soft, rich in chromic oxide, have a low silica content, and are free from objectionable impurities. Although the production has fallen off in recent years, the mineral is of widespread occurrence in Anatolia. The most important deposits are those at Dagardi.

Important Minor Minerals Include Borax, Emery and Meerschaum

Extensive beds of pandermite, a massive and not entirely pure variety of colemanite, are mined at Sultanchair, in the Province of Hudavendighiar. The principal operations are those of Borax Consolidated, Ltd. The mines lie on the mail route leading from Panderma harbor to Balikesser. The pandermite occurs in Tertiary sedimentaries lying in a basin surrounded by steep hills of gabbro, granite and crystalline schist. The productive beds consist of a brownish and bluish gray gypsum, containing nodules of variable sizes dispersed within the gypsum, and forming from 10 to 20% of the aggregate mass.

The production of emery from Asia Minor and the islands of the Ægean Sea practically constitute the bulk of the world's supply. The output of the former exceeds that of the latter. The mines lie in a belt extending south and southeast of Smyrna. The ore is found in lumps up to 15 cm. in diameter embedded in a red-brown clay and associated with calcite.

The plains near Eskischehir constitute one of the most important meerschaum localities in the world. The meerschaum district extends from the town of Eskischehir almost due eastward to the City of Angora. The mines lie at a distance of about 22 km. from the railroad station, to which the ore is packed by camel trains. The two chief producing mines are those of Sarasu and Sepki. The deposit occurs in a valley filled with drift material from the surrounding mountains. The sepiolite is scattered through the drift in rounded nodular masses, with fragments of magnesian and hornblendic rocks. As a rule the nodules do not exceed 10 cm. in diameter, but a few attain larger dimensions. In the raw condition the mineral is soft, light and nontransparent. The color is white, with occasional blending of yellow, red or gray. The thickness of the meerschaum-bearing strata varies between 3 and 10 m.

Other minerals have been mined or are known to exist in various districts of Asia Minor. Arsenical pyrite has been found near Odemich. Lithographic stone occurs in extensive massive beds north of Mihailich, also east of Kimasti and south of Abulonia Lake. Iron is found in many places in Asiatic Turkey. The region east of Adalia Bay was to have been the site of an exploitation, prior to the war. In the vicinity of Anamur, iron ore has been mined on a small scale during the last few years. This district lies at the foot of the southernmost projection of the base of the Tauric region, where various ores are reported to occur and within which mining has been carried on in a desultory fashion for over 20 centuries. Zinc also exists in this region. Zinc deposits at Karassi were worked prior to the war by the Société Anonyme Ottomane des Mines de Karassi.

Petroleum is found in the provinces of Erzerum, Mosul and Bagdad. The Mesopotamian deposit, probably an extension of the Persian field, promises to be of importance, and the Bagdad railway will give this field much needed transport facilities. Just before the war, the Turkish Petroleum Co. was formed[3] to exploit this area: half of the capital was British and the Deutsche bank and Royal Dutch Shell Trust each held a quarter interest. Further development with this combination of interests is now unlikely. Asphalt is known to exist at Anti Lebanon, Kerkuk, Hit and other places. Besides the mineral resources already mentioned, salt and sulphur are produced in a small way and precious stones are mined in a number of places.

American Mining Congress

In a letter to the members of the American Mining Congress, J. S. Callbreath, secretary, announces that for the better carrying out of the comprehensive plan outlined at the San Francisco convention to secure the cooperation of the mining men in this country in the betterment of mining conditions, one of the first steps is to secure more interest in the work of the congress. President Carl Scholz, in his plea for extension of membership in the congress, said that there are 90,000 men in the United States directly or indirectly interested in the operative side of mining. Probably there are not 20 men in the 90,000 who disapproved the objects sought by the American Mining Congress. But the organization has only 1,500 members, and this condition presents certain elements of unfairness. It allows the 1,500 members to work for, pay for and secure benefits for the profession in general, while the rest of the 90,000 enjoy them without any effort on their part. President Scholz believes it is the duty of all mining men to work for improvements in the profession and, to secure this end, pleads for an enlarged membership in the congress.

Illium Is the Name for a new acid-resisting alloy worked out at the University of Illinois and described by S. W. Parr at the recent American Institute of Metals convention. Its composition is given as: Cu, 6.42%; Mn, 0.88; Si, 1.04; W, 2.13; Ni, 60.65; Al, 1.09; Fe, 0.76; Cr, 21.07; Mo, 4.67; total, 98.81%; carbon and boron not determined. It is said to be entirely resistant to 25% HNO_3. Its properties are ascribed to a proper proportioning of electropositive and negative metals. Details of preparation are not given.

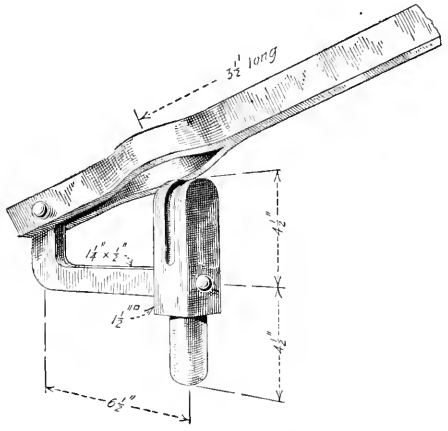
Details of Practical Mining

Home-Made Chuck-Bolt Bender

The accompanying sketch shows a home-made chuck-bolt bender that will be of great service to any blacksmith in making chuck bolts for piston drills. Without any



CHUCK-BOLT BENDER

device of this kind, it is necessary first to bend the bolt to shape and then to twist the ends apart so that the thread can be cut on each and then reheat the bolt and twist it back again. With this device it is possible to cut it and bend accurately with one downward motion of the lever.

Two Cornishmen and a Jackhamer

By Paul F. Chamberlain*

Thomas Pollard and Robert Bone, two Cornish miners, had a hand-drill contract in one of the drifts of No. 3 Alpena mine, Virginia, Minn. Their "dirt" had been very hard to break all during the month and they were making practically no headway. The two men concluded, along about the 20th of the month, that their contract price was not large enough for them to make a living wage. Accordingly they decided to call on the local superintendent, Charles Grabowsky, and ask him either to give them a better price or grant them company-account wages for the month.

Said Thomas to Robert, "Hi say, pardner, us ain't goin' to make our bloody sault this month. Let me and thee goas on up an' see Cap'n Charlie and see if 'ee won't give us company 'count for the month or else raise the price o' the contract."

It was so agreed; Thomas was to do the talking while his partner stayed outside. Thomas entered the office and doffing his hat said:

"Mornin' Cap'n; me and pardner 'ave a drif' contract down in the bal (mine) and we bean't makin' wages, and we thought as how us shouldest come up and talk to 'ee and see if thee couldent fix us up a bit. Say, give we company 'count for the month or raise the price a bit."

"Well now, my man," said the superintendent, "I can not do either at this time of the month, but I am going to send a jackhamer in your place tomorrow which I am sure will help you a whole lot."

"Thank 'ee, Cap'n, that's fair enough sure; we does need a bit of 'elp," said Thomas as he retired. To Robert he reported, "Pardner, we be all fixed up; Cap'n's goin' to send Jack 'ammer into our place to 'elp us out."

"That's fair enough," agreed Robert, "but 'oo the bloody 'ell is Jack 'ammer, never 'eard tell of 'ee. I naw Jack Thomas and Jack Williams, but I never did 'ear of Jack 'ammer; 'oo is 'ee?"

"I dinnaw 'oo 'ee is myself," answered Thomas, "but I speck 'ee's one of they there bloody Finlanders that's been 'angin' about the shaft all week!"

Foundation Bolts for Steel Chimneys*

As the rules suggested by engineers for the sizes of foundation bolts for chimneys vary widely, the following table has been compiled to compare this practice. The

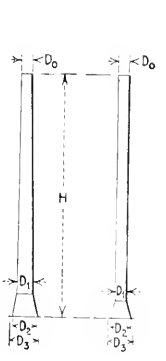

Fig. 1

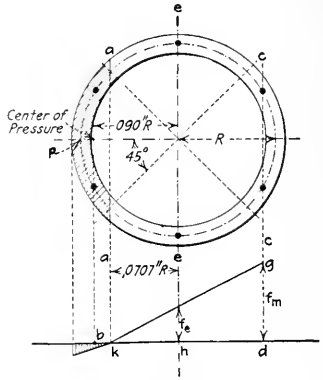

Fig. 2

OUTLINE OF CHIMNEY AND STRESS DIAGRAM FOR FOUNDATION BOLTS

first six chimneys are described in a published pamphlet and are said to have been built. The remainder have been built and are standing. Of the numerous formulas the two extreme ones may be put in the form,

$$f_m = \frac{M}{k \times N \times a \times R}$$

in which

*H. D. Hess, professor of machine design, Cornell University, in "Power," Oct. 5, 1915.

M = Moment tending to overturn the chimney, in foot-pounds;

N = Number of foundation bolts;

a = Minimum area of a bolt, usually at the root of the thread;

R = Radius of the bolt circle in feet;

f_m = Maximum fiber-stress in any bolt in pounds per square inch.

The value k varies with the different conditions and is given later.

If we assume the nuts brought to a bearing, with practically no initial stress and no wind acting, the center of pressure between the chimney and the foundation will coincide with the center of the bolt circle. If the wind now acts from the right the center of pressure will move toward the left, and at the extreme position it will approach the point p on the bolt circle. The formula giving the lowest stresses assumes this concentration at the point p and further assumes the fiber-stresses in the bolts proportional to their distances from a tangent through the point p. The value k is then 0.75 in the equation just given, and M is the wind moment less the righting moment. The latter is taken as the weight of the chimney in pounds times R.

In the formula giving the highest stresses the chimney is assumed as fixed at the base, the neutral axis being taken as e-e. If the bolts on both sides of e-e are effective they must resist compression, a condition here impossible of realization. When the formula is solved in this way k is approximately 0.50 and M is the full wind moment.

DESIGN DATA FOR STEEL CHIMNEYS

Design-ation	Chimney Diameters: Top D_0 Ft. In	Base D_1 Ft. In	Bell Base D_2 Ft. In	Bolt Circle D_3 Ft. In	Ht. of Chimney, H Ft.	Wt of Steel, Tons	Net Overturning Moment, Ft.-Lb.	Foundation Bolts: No.	Diam. In.	Maximum Fiber-Stress in Lb. per Sq. In.

20	5 10	7 8	12 0	12 6	125	24 7	1,281,270	8	2¼	12,700
30	7 4	9 6	15 9	16 3	175	45 0	3,183,165	10	2½	17,500
38	9 10	12 0	18 6	19 0	190	62 3	4,706,540	12	2½	16,000
45	11 10	14 8	25 0	25 6	300	140 7	14,218,000	16	2½	28,000
B	4 9			6 5	100	8 3	664,900	4	2¼	20,080
D	6 0		9 6	9 10½	125	16 0	1,263,700	4	2	41,400
E	6 6		9 0	9 4	120	15 3	1,276,400	4	2¼	27,500
F	8 0		11 3	11 7½	120		1,538,200	4	3	18,400
G	10 0		14 0	14 6	146	30 8	2,795,460	6	2¾	25,900
K	16 0			27 0	225	77 0	10,278,900	12	3	17,600
L	11 6			18 0	200	55 0	4,359,000	8	3¼	15,550
M	30 9½			51 0	400	438 0	41,518,300	36	4	6,780
R	8 0	12 4		21 1	217	65 0	4,683,800	12	2¼	11,950

A comparison of the data given in the accompanying table indicates that few of the 15 chimneys had been designed on either basis. It seems to me that a basis nearer the truth might be had by assuming in the extreme position one-quarter of the chimney base in contact with the foundation, as shown in Fig. 2 by the shaded portion. The neutral axis is a-a. The bolts to the right of a-a are stressed proportionally to their distances from a-a. The figure also shows the stresses in the concrete. The moment due to any bolt will be the product of its area, fiber-stress and the arm from the bolt center to a line through the center of pressure and parallel to a-a. In this case the value of k is 0.67. The overturning moment is here the wind moment about the base less $W \times 0.9R$. In all cases the wind moment equals the wind force on the chimney times the distance from the base of the chimney to the center of pressure of the wind force. For a cylindrical chimney this equals $\frac{D_1 \times H^2 \times w}{2}$ foot-pounds, where w, the wind pressure per square foot of projected area of the chimney, is usually assumed at 25 to 30 pounds. D_1 and H are measured in feet. The working fiber-stress may be taken from 12,000 to 16,000 lb. per sq.in. The maximum calculated fiber-stresses based on a wind pressure of 30 lb. are given in the right-hand column of the table.

How To Choose Rock Drills

By J. R. McFarland*

Of what type of drill, Mr. Mine Manager, was that last order? Were the drills selected after a careful test which demonstrated them to be of the type best adapted for drilling in your own mine, or were they chosen at random?

With the keen competition nowadays between drill manufacturers and the resultant radical improvement in rock drills as a whole, inasmuch as the drilling cost is a large factor in producing the ore it behooves the active mine manager to make frequent tests to determine on which type of drill to standardize.

Different Classes of Drill Buyers

A considerable number of the older managers and superintendents have used one or two sizes of a standard type of machine for years—usually a one-man and a two-man drill. A large sum of money may be tied up in repair parts. Their machine shops may be making a considerable number of the parts for these drills, thus reducing the cost for repairs. This makes it very hard for a manager to get away from the old type of drill, even though he may be convinced that a newer type is better.

There is also a class that tries everything that comes along and as a result accumulates a motley variety of machines, which causes an extraordinary amount of confusion in and about the mine. A full supply of repair parts has to be kept for each machine, thus involving a much greater amount of money invested in repairs than would be, if only one or two types of machines were used; also, the master mechanic has a much harder time keeping the drills in good repair. Probably the greatest trouble is underground, where the miner may find that the steel does not fit his machine or the hose and connections are not of the right size or have a different thread; or the column, arm or bar and wrenches may be of wrong size. Such trouble causes an extra trip to the surface and maybe the loss of the round for that shift. In losing the round the cost for practically the same advance is doubled. So it is no wonder that some of the older heads feel just as well satisfied to "pass up" the pastime of drill testing.

However, a majority of managers try to keep up with the drill problem, standardizing on one or two of the later types. They figure that the increase in speed and the greater economy in air consumption and repairs more than pay them for the loss in throwing away the old repair parts and designs. In the larger mines and many of the smaller ones the matter of drill testing is gone into with the foregoing facts in mind and with the idea of standardizing on one type of drill for each kind of work.

At a surprising number of mines no systematic attempt is made at testing. The drill is given to the

*5710 Kimbark Ave., Chicago, Ill.

runner; the mine foreman or shift boss may stop for a few moments to watch the drill run; the superintendent may hardly notice it as he passes by on his daily rounds; and the manager often never sees the drill at all. In most cases it is left to the runner, and if he likes the machine it is kept. Or if it is a little heavier, even though much faster, than his old one, or if it is one of the newer types which he has not yet learned to run, he will say that the drill is no good and it will be returned.

It is therefore necessary that the trial should be given the best attention and a record kept, or the test may as well not be made at all.

How the Test Should Be Conducted

To go into the problem properly, the following investigation, or one with the same object in view, should be made.

The machine is first taken to the machine shop and placed on the bench. The drill should be taken apart by the master mechanic and a report made on the following items:

1. What points of design?

2. What does the drill promise as to probable repair cost?

3. What air consumption?

The chief points of design are as follows:

a. Are the arrangement and design of the various parts such as to give the least wear or strain?

b. Does the type of chuck enable a rapid change of steel, and does the chuck hold the steel in alignment or not?

c. Are the front head and bushing or gland of proper design and strength to withstand the constant blows of the piston?

d. If a piston drill, is the piston stem of sufficient size and strength to withstand the heavy side strain and does the piston head have sufficient length of bearing to hold the piston in alignment and prevent serious cylinder wear?

e. If a hammer drill with a striking block, or anvil, is the striking block heavy enough?

f. What is the diameter of the cylinder?

g. If a self-rotating hammer drill, how is the rotation transmitted from the piston to the steel? Is rotation positive or not?

h. Is the rifle bar strong enough?

i. Are the ratchet ring and pins or pawls and springs of good design and easily assembled?

j. Is the back head well designed?

k. If a water or hollow-tube machine are the tube and packing so designed as to give little trouble and be easily accessible?

l. The valve chest is very important. Does it freeze or not? Does it use air wastefully? Is it in the way when extracting steels from the holes?

m. If a stoper, is the feed piston of proper size for your air pressure? Is it of sufficient strength to withstand hard blows?

n. Is there any special benefit from the arrangement of the side rods, springs, throttle valve, oiling device, hose connections, shell, etc., of the machine in question?

o. What is the weight of the machine?

p. Finally, are the parts that are subject to the greatest wear and strain made of properly treated and worked steel or are they made of cast iron?

The master mechanic is able to tell to a great extent, from the foregoing investigation, whether many parts will be broken and whether such parts as are ordinarily expected to break in time will cost much to replace. If the company maintains an elaborate machine shop, the master mechanic may figure on the number of parts he may be able to make himself. An accurate record of repair costs should be kept to determine whether the superior speed of one drill is not more than counterbalanced by the low repair cost of another.

As a rule, only a few mines have any apparatus to test the air consumption. Machines for testing may be purchased from various drill and machinery companies.

The displacement-tank method, while rather cumbersome and expensive, is always reliable. In this, water under pressure is used to displace the air from two receivers alternately. The drill is run from the air thus expelled. The quantity of air consumed by the drill is figured from the amount of water that displaces it. The amount of water is indicated by the height in the water gages on the two receivers. Air meters are constructed on the principle of the fan or bellows or a combination of both. They are not usually so reliable as the displacement-tank method, but are less cumbersome. However, if two drills are tested at the same pressure, a reliable comparison can be obtained.

An inexpensive way to obtain a comparative test of two machines is to fill a receiver with air to a certain pressure and run each machine in turn from the receiver, noting the time necessary to reduce to various pressures. It is obvious that the drill that reduces the pressure to the lowest point in a given length of time uses the most air. However, owing to the different valve designs, some drills use proportionately more air at some pressures than at others, and this fact has to be kept in mind in such a test.

A very few mines have an elaborate system of testing the strength, nature and rapidity of the blow of a machine. This test is not essential, although it is well to know, if possible, just how the drill in question compares with others in this respect. This test is valuable in testing drills after they have been in use for some time. An exhaustive consumption of air generally shows that the piston or cylinder or both are badly worn. If the air consumption is no more than proper but the blow is weak, it is likely that the trouble is in the valve or valve ports. If the valve "flutters," it is generally a sign of excessive cylinder wear, as the air is allowed to pass by the piston and into the reverse ports, thus reversing the stroke prematurely.

As a general thing, a light, rapid, tapping blow is best adapted for soft ground, while a heavy, slugging blow is best for harder rock. However, it is difficult to tell from this kind of a test just what drill is going to do best in your ground and the only sure way to find it out is by the actual drilling.

Making the Underground Test

Having made the tests above ground, the next thing is to prepare for the underground test.

A suitable face to drill in must be selected. This is a point where mistakes are sometimes made. There is a tendency on the part of the superintendent to pick the hardest rock in the mine. This should not be done unless the sole object is to test the strength of the drill.

The rock chosen should be a fair average of what is encountered in the mine. A drill specially designed for hard rock would make the better showing if tested in the hardest rock in the mine; while another drill, adapted to the average mine rock, would not do so well in the hard rock, but would do much better than the other in the average rock that has to be drilled.

Drill Type Must Fit Conditions

In this connection it may be said that it does not usually matter so much what make of drill you buy, as that the drill should be selected for the special conditions in your mine.

In a great many mines, most of the attention is given to the studying of the ore formation and little toward cutting down the production costs. It is in such mines that contractors thrive, as they are able to give their whole attention to progress.

In such mines, where no special effort is expended toward drilling efficiency, or in portions of mines that are working in ore, or where water is hard to obtain, it may be best to use the one- or two-man solid-piston machines, depending on the hardness of the ground. This is particularly so in stopes and sublevels, where the machines have to be taken up and down chutes or ladderways and where it would be too much bother to take water and the extra fittings for the water drills. If possible it is best to use self-rotating hammer drills for drifting in such places. This method of drilling often doubles the speed on account of the fact that no mounting need be used. It is desirable to use the hammer drill with water through the steel. If air is used through the steel, a spray or atomizer should be attached to lay the dust as it is blown from the hole.

If much attention is given to speed, a water drill should be used if possible. Such a drill is best adapted to the driving of long drifts in development work. If the ground is soft or if the rock is "ravelly," with much fine rock falling in behind the bit, it is often best to use a water-piston machine. The action of the alternating water and air jet, together with the reciprocating motion of the steel, always leaves the steel free to be pulled from the bottom of the hole. If the water-hammer drill be used in such ground more time is often required to extract the steel than to drill the hole. If in hard, solid rock, the water-hammer drill will probably give as great or greater speed than the water-piston machine.

For sinking work either the heavy two-man solid-piston drill or hollow-piston two-man machine can be used. The latest and most popular method of shaft sinking is with the self-rotating hammer drill. With this machine the round can be drilled in less time as no mounting is used. The holes also can be spaced better and drilled at more advantageous angles, thus "pulling" the ground better.

After a suitable place is selected, proper steel should be prepared. The bits should be well formed and tempered for the rock selected and the shanks made the right size. Proper mounting, wrenches, hose and connections must be provided. A pressure gage should be placed at the end of the air-pipe line if one drill is tested at a time.

In testing, one man should be detailed to keep an accurate record of all operations, taking readings of the air pressure every 10 minutes or so, if much variance is had, or every half-hour if the pressure is fairly constant. If a comparison is to be made with another drill, care should be taken to have all conditions as nearly alike as possible. The test should be conducted by the same person and the same drill runners, using the same gage of steel and as close as possible to the same average air pressure. The following report should be made, the example including actual test figures.

1. Type of machine: Sullivan FF-12 Water Drill, size 2⅝ in., weight 162 lb.
2. Place of work: American Flag Mine, Park City, Utah., north heading, 900-ft. level.
3. Date: July 30, 1913.
4. Kind of ground: easy-drilling quartzite.
5. Character of work: drifting; size of drift, 5x7 ft.
6. Type of mounting, column and arm.
7. Average depth of hole, 6 ft.
8. Gage of steels: Starter, 2½-in.; dropped ¼ in. gage on each change of steel.
9. Air pressure at drill, 80 lb.
10. Time of starting work, 7:30 a.m.
11. Time of stopping work, 1 p.m.
12. Total elapsed working time, 7 hr. 30 min.
13. Exceptional delays, none.
14. Total elapsed drilling time, 5 hr., 30 min.
15. Total net elapsed drilling time, 2 hr. 30 min.
16. Actual net reciprocating time, 1 hr. 30 min.
17. Number of holes, 9.
18. Total footage, 54 ft.
19. Drill speed, average inches per minute: (a) Total elapsed drilling time, speed 2 in. per min.; (b) net elapsed drilling time, 4.3 in. per min.; (c) actual drilling time, 7.2 in. per min.
20. Number sticks of dynamite, 27; strength, 40%.
21. Results: (a) Advance, 5½ ft.; (b) cars of muck removed, 20.
22. Name of runner, John Doe.
23. Name of official in charge of test, John Smith.

Remarks on the Form for Reporting Test

1. The type and size of machine should be stated as a matter of record. The weight must be suited to the work and hardness of the rock.

2 and 3. The location and date are a matter of record.

4. In giving the report it is essential to show the class of rock and hardness in order to make any just comparison. A drill that drills 7 in. per min., actual drilling time, in medium-soft rock, may not drill 1 in. per min. in very hard rock.

5. The character of the work is a matter of record and must be stated before the operations can be completely understood. The size of the tunnel, shaft or stope should be given for the same reason.

6. It is well worth while to show the type of mounting used, as considerable time may be gained or lost from this cause. If a piston drill is used in a stope with a column mounting, it is quite possible that a hammer drill may be substituted and save an hour or two of time by the omission of setting up, tearing down of the column and the time lost in changing positions on the column.

If only one shift drills and the next shift mucks out, it is best to use a vertical column, as a "clean" set-up is afforded when the drill shift goes on. The column permits vertical as well as horizontal shifting of the drill and gives the runner a better chance on a "running" hole. However, if drilling is to be done on the same

shift as the mucking, it is often advisable to use a horizontal bar. While drilling is harder and a better runner is required to "bottom" his holes, yet the bar can be set up at once; but if the vertical column is used, an hour may be spent in "mucking back" to clear a place to set the column.

Sometimes, when the ground is favorable, all the holes can be drilled from one set-up. Even though the bar has to be lowered for the bottom holes, only a few minutes is required, as compared with a possible hour lost in "mucking back."

As the "mucking back" is only a waste of high-priced driller's time and the work is a total waste, the muck having yet to be shoveled into the car, the use of a bar wherever possible cannot be too strongly emphasized.

Slick Sheets Should Be Used in Shoveling

It is also surprising how few mines use boards or "slick sheets" for the muck to be shoveled from. A few minutes spent each shift in handling the "slick sheets" will save the mucker an amazing amount of time and energy. Rapid mucking also helps the drilling, as the muck is cleared away from the bottom of the face by the time the runner reaches his lifters and he is not forced to wait or take the valuable time at the end of the shift to scrape the muck back.

The length of the shell depends on the hardness of the ground. If it is very hard, the holes have to be inclined at steep angles in order to break the ground. To drill thus, the shell must be short so that the roof will not interfere with the crank handle. Also, in hard ground, with a long feed the gage may wear off the steels to such an extent that they will not "follow." If the rock is soft, a long feed is desirable and time is saved in changing steels.

7. In even rock the cuts and lifters should be drilled somewhat deeper than the other holes, to maintain an even face, as they are drilled at a greater angle and do not penetrate as far directly into the "face" as the "flatter" holes.

8. The gage of the bit is important. The smaller the bit, the faster will the rock be drilled. However, the hole must be large enough at the bottom to take the powder and hold enough at the bottom of the hole to break the rock. If another drill is to be compared, it is quite important to test with the same gage of bit.

It is quite obvious that attention should be given the bits and that they should not only be tempered for the rock to be drilled, but should be well formed so as not to retard the speed of drilling. If the rock is so hard that trouble is experienced in making the steels follow, give a greater difference in the changes of gage.

The breakage of drill steel should be noted. Little trouble is had with piston-drill steel breaking, but some types of hammer drills, because of the heavy blow delivered direct to the steel by the piston, cause crystallization and excessive breakage.

9. The air pressure in some mines may vary at some places and on some days 20 or 30 lb. This may be caused by a pipe line of too small diameter. When several machines are running close by or someone is "blowing off," the pressure drops abruptly. For this reason it is desirable to have sufficient air pressure in order to make a fair comparison, and absolutely necessary to have a correct record of the average air pressure.

In this connection it is surprising how little some superintendents know about the air pressure on which their drills are running. Many drills that are generally supposed to be running on 75 to 80 lb. of air are running on only 50 to 60 lb.

If two drills are tested at the same time on the same bar or on columns in the same tunnel or drift, the air gage is not so essential, as both the machines have the same air pressure. However, the pressure should be kept up to normal for the reason that one drill may give a much better performance on a low air pressure than another. Owing to this fact, the pressure should be close to that which is customary in the mine, so that the test may parallel mine conditions.

10 and 11. The time of starting and stopping work is a matter of record. In this case while the full shift was 8 hr., the time given was only 7 hr. 30 min., as this was the time actually at the face. Usually a good deal of time is "killed" around the beginning and end of a shift. In the larger mines a considerable length of time is consumed in getting the steel together and reaching the working place. Then if the work is day labor and the boss is not around, a nice long rest and a smoke are in order.

At the end of the shift the men have to be ready by the time the men in the next place to them "fire" or they have to leave the round unfinished. For this reason the runner always tries to get his place ready to shoot 15 min. or more before the usual shooting time.

12, 13 and 14. The difference between the total elapsed working time and the total elapsed drilling time (from the start of the first hole to the bottom of the last) was in this case 2 hr. About one hour was used in mucking back for the column and setting up. The other hour at the end of the shift was used to tear down the column, take the machine and equipment back to a safe distance and load and shoot the holes. The time consumed in setting up was afterward cut down from 1 hr. to 15 min. by the substitution of a crossbar.

No Nuisance Worse Than Drills Freezing

In order that the test should show up the drill fairly, any unusual delays should be recorded. In a mine, time can be lost in a multitude of ways. The steel may not have been tempered correctly and the drills may all be dulled before finishing the round. Where miners have to "rustle" their own steel, it is hard to get them to provide enough. Where the ground is soft, it is often hard to keep the bar or column tight. Hose troubles can be avoided to a great extent by running the hose on boards over the heads of the muckers. But none of the foregoing troubles can compare to the freezing of a drill. In quite a large number of mines there are too few receivers to catch the water and too little attention is given toward draining off the water from the receivers. It is left to the foreman, and as he is little bothered with freezing in his climbing up and down ladderways, the matter is neglected.

It has also been found that in wet mines, when the air is off between shifts, considerable water leaks in the submerged pipes. On a wet day outside, the freezing of the drills is more noticeable, as an unusual amount of moisture is taken into the compress. The freezing not only delays the drilling, often causing the loss of the round, but also causes the piston frequently to

kick the back head out. While numerous suggestions have been made to keep the valves from freezing in rock drills, usually none of them is of much effect. As some types of valves have less tendency to freeze, or are entirely free from freezing, it is best to use such types where much water is found in the air.

15 and 16. The difference between the net elapsed drilling time, (from collars to bottoms of holes) and the actual net drilling time (time machine is in actual operation) shows how much time is taken up by changing steels and position, if we leave exceptional delays out of our consideration. In the case cited, the difference was one hour.

How Long Do the Drills Work?

It surprises some people to know the small amount of time the drill is actually running. In this case it was 1 hr. 30 min., or less than 30% of the total time between the beginning of drilling and the end of the round. As this is unusually fast drilling for mine work, 30% is unusually low. The softer the rock and faster the actual drilling, the lower will be the percentage. And in harder ground more time will be taken up in actual drilling and the percentage may rise to 60% or higher.

17. The number of holes and their depth depend entirely upon the ground. The harder the rock, the greater the number of holes to break it and the shallower they are drilled.

18. By adding the depth of each hole the footage is obtained. The footage drilled is, roughly, a measure of the speed of the drill, and if no complete record is made this measurement should be taken.

19. The average rates of drilling, in inches per minute, tell the experienced superintendent most of what he wants to know, before looking at the rest of the test. Of these averages the actual drilling time is the most important.

20. The strength of the dynamite and the number of sticks are an indication of the hardness of the ground.

21. The final results of the whole test, which every mine manager wants to see, are the number of feet of advance and the number of cars of ore broken. Knowing this, he is able to figure his drilling cost per ton, per cubic yard or per foot of advance. If in development work, the advance is the main object and the one on which the manager figures his expenses; if in ore, the number of tons of ore broken by the shot is where the profit lies. If two tests are run in the same-sized drifts in rock of the same hardness, these figures are easily obtained and constitute an approximate but final test of the speed of the machines.

22 and 23. The names of the runner and official in charge of the test are a matter of record.

In a test of two drills at the same time, it is best to change the drillmen from one machine to the other so as to equalize their skill. If the machines run pretty close together in speed, the change may be made in the middle of the shift. If, however, one machine does considerably better than the other, the changes should be made more frequently, as there is a tendency for the drill runner who is ahead to favor that drill; and if, when the change is made, the other drill is much behind, he will most likely slow up and not try. However, if a fairly equal progress is made, the drill runners will give an unusual exhibition of energy, for it is human nature for each one to think that he is just a little better than the next one. Such a test should be conducted on the same basis as the previous one with the exception of items 20 and 21, which may be omitted, as they have no bearing in this case.

Methods Used in Testing Stoping Drills

If one stoping drill is to be tested, the method is the same as that of one rock drill. In testing two stopers against each other, the simplest and possibly the most efficient method is to place the two drills side by side, along the side wall of a heading. The positions of the holes to be drilled are marked off with a piece of chalk. One hole should be inclined as close to the horizontal as the cuttings will fall out, and about three more holes drilled at various inclinations up to the vertical. Several series of these holes should be marked.

After plenty of steel has been obtained and the runners have made sure that they will "follow" and that there will be no delay, the drills are started on the same corresponding holes and run continuously for a half-hour, over-all time, changing the drill runners frequently from drill to drill. The holes should all be drilled to approximately the same depth, unless a steel should become seriously stuck. At the end of the time, the holes are measured and it is pretty safe to assume that the drill that has drilled to the greatest depth is the fastest machine and best adapted to the ground.

Drilling Thirty Feet in Thirty Minutes

A case came under my observation at the Veteran Shaft of the Nevada Consolidated Copper Co., near Ely, Nev., where one stoper, when tested as to actual drilling speed, drilled 35% faster than the other. When placed side by side and the foregoing test run, the first stoper drilled 20 ft. in a half-hour and the apparently slower one of the two, when judged from the first test, drilled 30 ft. in the same time. This change in comparison was caused by the fact that the feed cylinder on the first machine was too large, which, although it caused the machine to drill faster, at the same time caused it to "bury" the bit in the softer ground, and in the "flatter" holes the machine drilled so fast that the cutting did not fall out fast enough and again caused the bit to stick. While the first drill would probably have been the faster one in a little harder rock, this test proved conclusively which was better adapted to drilling in the ground in question.

In this connection, I wish to say that this was the fastest drilling I ever saw. The average of a foot a minute for a half-hour, over-all time, was the result of the extraordinary pace set by the runners; the fact that the steels were handed to them and the time elapsed for changing each steel probably did not exceed a few seconds. The rock was soft, dry porphyry and unusually easy drilling.

In conclusion, the mine manager must have the following information in order to know absolutely which drill is the most efficient for his mine: First, he must have the report from the master mechanic on repair cost and air consumption; next, he must have the results of the underground tests on drill speed and work accomplished; finally, with this information before him, he must figure out the drilling cost per ton or per cubic yard of rock removed or per foot of advance.

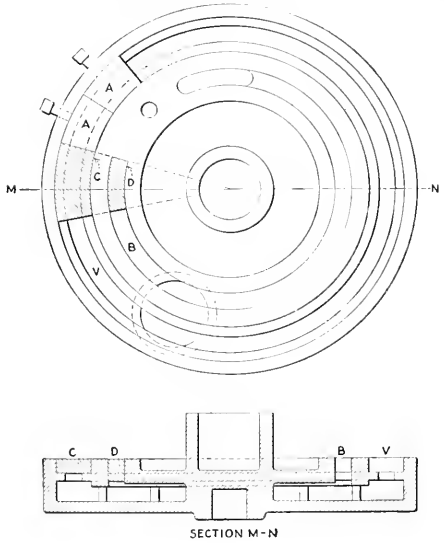
Details of Milling and Smelting

Raising Drum-Filter Vacuum

By Herbert G. Thomson*

It is sometimes necessary to run filters of the rotary-drum type with a low pulp level in the tank on rapidly settling slimes. A reduction of vacuum will result, owing to air passing through the canvas on the two or three exposed sections of the drum between the blowoff and the pulp level. The following simple method of increasing the vacuum was used at the Globe Consolidated mill, Dedrick, Calif.

A wooden block *C* was carefully fitted into the annular vacuum slot *V* in the exterior section of the head valve, of sufficient length to cover entrance holes of pipes leading to the two exposed sections of the drum. Since the



METHOD OF BLOCKING THE VALVE PORTS

blow and vacuum slots are connected below the blowoff point, it was necessary to insert a similar but shorter wooden plug *D* in the blow slot *B* covering the two corresponding pressure-pipe holes. The faces of the two blocks were flush with the face of the valve. Upon being moistened with solution the wood expanded and fitted tightly, effectually shutting off the vacuum from the exposed sections. As a result the vacuum was raised nearly three inches, with the result that the cake was held more securely on the drum and filtration was carried through more rapidly.

A glance at the accompanying sketch will show that the changes made were, in effect, merely the lengthening of the two steel blocks *AA* inserted in all machines by the manufacturer. When run normally, with the tank nearly full of pulp, these are of ample length to prevent loss of vacuum.

*Globe Consolidated Mill, Dedrick, Calif.

Concentration Formulas

By J. E. Clennell*

In certain cases some ambiguity occurs in the interpretation of the results of small-scale concentration tests, owing to the presence of factors that would be eliminated in practice. In a small test it is usually impossible to obtain a close concentration of the valuable mineral in one product, and produce clean tailings in a single operation. Usually a considerable amount of middlings is produced, which must be worked over repeatedly to obtain the desired result. This applies both to gravity concentration and to flotation.

By making certain assumptions, however, we may calculate the effect of this repeated concentration without actually performing the operation. In practice, the middlings, if produced at all, are continuously returned to the head of the machine, and it may, in general, be assumed that the assay value of the clean concentrates and tailings produced is not affected by this procedure. This assumption, which is the basis of the following formula, appears to be legitimate—at least in cases where the heavy or floatable mineral is substantially of one kind, so that the middlings are not of a different nature from the ore itself, but consist merely of a mixture of the same constituents found separately in the concentrates and tailings.

Let *C*, *M* and *T* respectively represent the percentage weights of concentrates, middlings and tailings obtained in the actual test; *X* and *Y*, the required percentage weights of concentrates and tailings that would be obtained if middlings were eliminated; *h*, *c*, *m* and *t*, the assay value (in any unit) of heads, concentrates, middlings and tailings respectively; *x* and *y*, the required percentage of total value in concentrates and tailings respectively, when middlings are eliminated. Then since

$$C + M + T = X + Y = 100$$

and

$$Cc + Mm + Tt = Xc + Yt$$

it follows that

$$X = \frac{Cc + Mm - (100 - T)\,t}{c - t} \qquad (1)$$

and

$$Y = \frac{(100 - C)\,c - Mm - Tt}{c - t} \qquad (2)$$

also, since

$$x : 100 : : Xc : 100\,h$$

and

$$y : 100 : : Yt : 100\,h$$

$$x = \frac{Xc}{h} \qquad (3) \qquad \text{and} \qquad y = \frac{Yt}{h} \qquad (4)$$

*Metallurgical chemist, Butters Patent Vacuum Filter Co., Oakland, Calif.

As an example of the application of these formulas we may take the following figures from an actual concentration test. The head assay showed gold, 0.895 oz. per ton.

DATA OF CONCENTRATION TEST

Product	Weight, %	Assay of Product, per Ton, Gold, Oz.	Per Cent of Total Gold
Concentrates	12 45	6 53	90 8
Middlings	11 45	0 35	4 5
Tailings	76 10	0 055	4 7

It is desired to find the effect of eliminating the middlings in this statement.

Here $U = 12.45$, $M = 11.15$, $T = 76.1$, $h = 0.895$, $c = 6.53$, $m = 0.35$, $t = 0.055$.

From (1)

$$X = \frac{(12.45 \times 6.53) + (11.45 \times 0.35) - (100 - 76.1) \times 0.055}{6.53 - 0.055} = \frac{83.9915}{6.475} = 12.97$$

From (2)

$$Y = \frac{(100 - 12.45) \times 6.53 - (11.45 \times 0.35) - (76.1 \times 0.055)}{6.53 - 0.055} = \frac{563.5085}{6.475} = 87.03$$

From (3)

$$x = \frac{12.97 \times 6.53}{0.895} = 94.63$$

From (4)

$$y = \frac{87.03 \times 0.055}{0.895} = 5.35$$

The result of the test then appears as follows:

DATA ON CALCULATED CONCENTRATION TEST

Product	Weight, %	Assay of Product per Ton, Gold, Oz.	Per Cent of Total Gold
Concentrates	12 97	6 53	94 63
Tailings	87 03	0 055	5 35
			99 98

Michaud & Delasson's Process of Tin Refining

A process for refining tin electrolytically has been patented by Georges Michaud and Eugene Delasson of Montreuil, France (U. S. Pat. 1,124,345). The electrolyte consists of $SnCl_2$, 100 parts; H_2SO_4, 10 parts; $MgCl_2$, 1 part; and boric acid, 1 part, made up in a solution of 20° Bé. The cathode is to have a surface equal to 2% of that of the anode, and the tin is deposited in noncoherent form and later scraped off the cathode which is preferably of copper. The solution is continuously regenerated by circulation through a tank containing tin waste of any sort whatever.

Sulphur Dioxide Recovery, Garner Process

Sulphur dioxide may be recovered from gases comparatively poor in it, according to James B. Garner, of Pittsburgh, Penn., assignor to the Metals Research Co., of New York (U. S. Pat. 1,145,579), by passing the gases at room temperature, say 11 to 24° C., over charcoal, when the SO_2 is absorbed, and later heating the charcoal to from 130° to 180° C., when the SO_2 is expelled. The enriched gas, which, the author says, may occasionally carry even 98 to 99% of SO_2, is recovered and used. He also calls particular attention to the fact that various charcoals have different affinities for sulphur dioxide, and particularly recommends the use of boxwood.

System of Zinc-Shaving Disposal

By Jesse Simmons*

At the Wasp No. 2 mill, Flatiron, S. D., the shavings cut on the zinc lathe for use in the precipitation boxes are conveyed in a short chute through a partition and thence drop to the floor of the precipitation room. The accompanying illustration shows the shavings coming through the chute and piling up on the floor.

SYSTEM OF HANDLING FRESH ZINC SHAVINGS

This, or a similar method, is essential to quick production of the material. To allow the shavings to drop into small boxes on the floor behind the lathe necessitates frequent changes of the boxes and stoppage of the lathe. This scheme gives plenty of room for an entire roll of zinc, cut into shavings, to pile up out of the way. It requires practically no attention on the part of the lathe man.

*Deadwood, S. Dak.

The Assayer and Chemist

The Ignition of Magnesium Pyrophosphate

In making determinations of phosphorus or magnesium, it has been found difficult to ignite the magnesium pyrophosphate to complete whiteness, even with greatest care, when the usual methods are followed, says S. H. Champlin in the *Chemist-Analyst*, July, 1915. The operation may be carried out quickly and easily as follows: Place the wet filter and precipitate in a Vitreosil crucible and dry over a low flame, inclining the crucible on the triangle and resting a cover against the top so as to cause the warm gases to circulate over the paper. When the paper begins to brown, place the crucible, uncovered, in a muffle below a red heat and smoke off the paper. Cool, and saturate with nitric acid (sp.gr. 1.42). Warm gently to expel the excess of acid, increasing the heat slightly until red fumes come off. Return to the muffle, now at a dull-red heat, and ignite until the evolution of red fumes ceases. Then raise the temperature to a bright-red heat and ignite until constant weight is obtained.

The use of a platinum crucible has never been attempted on account of the danger of alloying.

*

Assaying Samples Containing Coarse Gold

In a discussion of the influence of coarse gold particles on assaying, before the Institution of Mining and Metallurgy, W. H. Goodchild (*Bull.* 101) suggests that for spotty ores containing large particles of gold the best method is often to reduce 10 lb. to 40-mesh and pan the entire amount. The pannings should next be assayed separately as "metallics" and the tailings dried, cut down, ground and assayed in the usual manner. The final assay is then computed from the tailings and metallics assays.

This is very reminiscent of the method adopted by Sidney Jennings in his valuation of the Alaska Ebner mines, where 30-ton samples were put over concentrating tables and about 1½% concentrated out, carrying the free gold, pyrite, galena, etc. The concentrates were then treated in an amalgamating barrel. The tailings from the Wilfleys and from the barrel were easily sampled and the final assay was then calculated from the barrel recovery, the barrel tailings and the table tailings. In this way concordant results could be obtained.

*

Exact Determination of Sulphur Dioxide in Air

By J. R. Marston*

In the spring of 1910 it was necessary to devise a method for accurately determining minute quantities of sulphur dioxide in the air in the vicinity of the Selby Smelting and Lead Co.'s Plant, at Selby, Calif. A method was worked out and satisfactory results were obtained. Later, in May, 1913, the Selby Smelter Commission was appointed and a large amount of work was done in checking up the method, under the direction of A. E. Wells, chief chemist for the commission. All possible sources of error were investigated and different methods of manipulation studied, the degree of accuracy and technique being improved, so that the sensitiveness is one part in ten million. The method finally adopted by the commission is as follows:

Preparation of Apparatus

Take two clean glass aspirators of about 25-liter capacity, having one tubulure at the top and a second at the side near the bottom. The upper tubulures are closed with single-bore rubber stoppers carrying glass stopcocks and the lower tubulures with single-bore rubber stoppers fitted with glass plugs.

To make a determination, mix 100 c.c. of starch solution with 400 c.c. of distilled water, add 3 grams of KI and sufficient *N* 500 iodine solution to produce a good lavender tint. Divide this solution between two wide-mouth bottles of about 500-c.c. capacity each, fitted with three-hole rubber stoppers. (These will be referred to as titration bottles.) One hole carries a tube extending to the bottom of the bottle, the second carries an L-tube extending just within the stopper and the third hole is open. Insert the L-tube of each titration bottle in the rubber stopper at the side of the corresponding aspirator, close the third hole of the titration bottle with a finger and allow the starch solution to run into the aspirators. Detach the titration bottles, close the hole in the aspirator stoppers and shake the aspirators vigorously for about a minute. Return the starch solution from each aspirator to its titration bottle and compare the colors. The shade should be identical; but if not, pour the two portions together, mix, divide the solution and repeat the foregoing operation until the colors do match.

For an actual determination, the two 250-c.c. portions of colored starch solution are run into the respective aspirators. One aspirator is evacuated to a pressure determined by a mercury manometer, the stopcock at the top is opened and the sample of air to be tested drawn in. Shake the aspirators for one or two minutes and return the starch solutions to the titration bottles for comparison. *N* 500 iodine solution is added to the solution from the test aspirator until its color exactly matches that of the solution from the control aspirator. The iodine solution is drawn from a burette fitted with a narrow tip, which is passed through the third hole of the titration-bottle stopper, thus avoiding exposure of the solution to the air. If the starch solution from the test aspirator has been completely decolorized, both solutions are returned to their respective aspirators (after the addition of the iodine solution), the aspirators shaken for one minute and the comparison repeated as previously cited. This

*Chief chemist, Selby Smelting and Lead Co., Selby, Calif.

procedure is continued until the colors of the two solutions exactly correspond.

When 1 c.c. of N 500 iodine solution is equivalent to 0.0224 c.c. SO_2 at standard conditions, this factor multiplied by the number of cubic centimeters of $N/500$ iodine solution required to bring the solution from the test aspirator to the same color as that of the control aspirator gives the volume of SO_2 at standard conditions.

$$\frac{\textit{Vol. asp. in c.c.} \times 273 \times \textit{man. reading in mm.}}{\textit{Abs. temp. of the air in asp.} \times 760} =$$

volume air, standard conditions.

$$\frac{\textit{Vol. } SO_2 \textit{ at st. cond.}}{\textit{Vol. air at st. cond.}} \times 1{,}000{,}000 =$$

parts per million of SO_2.

Example:

Volume of aspirator	24,000 c.c.
Manometer reading	380 mm. Hg.
Temperature of air in aspirator	20° C.
N/500 iodine solution used	1.2 c.c.

1.2 × 0.0224 = 0.027 *c.c.* SO_2 *at standard conditions.*

$$\frac{24{,}000 \times 273 \times 380}{(273 + 20)\ 760} = 11{,}200 \textit{ c.c. air at standard conditions.}$$

$$\frac{0.027}{11{,}200} \times 1{,}000{,}000 = 2.5 \textit{ parts per million } SO_2.$$

To prepare the iodine solution, weigh out 1.27 grams of pure iodine and 5 grams of KI and make to 1 liter. Dilute 200 c.c. of this solution to 1 liter, which gives an $N/500$ iodine solution. The starch solution contains 2 grams per liter.

The control bottle is used to check a volume of air free from SO_2 against an equal volume of air which may contain SO_2. It compensates for the iodine consumed by substances contained in the water, etc. KI is added to the starch solution to increase the sensitiveness of the reaction. The lavender end-point is more sensitive than the blue.

It is impractical to evacuate a 24-liter bottle below one-half an atmosphere, as it is liable to collapse.

The two-minute shaking gives ample time for the SO_2 to react with the iodine. The two portions of starch solution are mixed at the end of each test, then divided, when the solutions are in readiness for the next test.

::

Determining Lead as Sulphite

An investigation of the suitability of lead sulphite for the gravimetric determination of lead is described by George S. Jamieson, *Am. Journ. Sci.*, p. 157, 1915. Lead may be precipitated quantitatively from a slightly acid solution by sodium or ammonium bisulphite, or even by aqueous sulphurous acid, if the acidity of the solution be carefully controlled. When a solution contains much acid it should be almost neutralized with ammonium hydroxide before attempting to precipitate the lead.

A 2% solution of bisulphite should be added in excess to the lead solution, the solution thoroughly stirred and allowed to settle for an hour or longer. The precipitate is then filtered on a Gooch and thoroughly washed with cold water. The liquid should not be allowed entirely to pass out of the Gooch until the washing is complete. This is very important. The lead sulphite is then dried at 150° C. for an hour and weighed as $PbSO_3$. Alkaline-earth metals interfere, being precipitated with the lead.

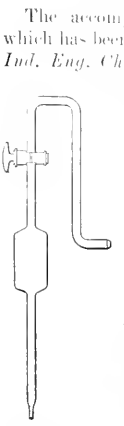
A Modified Pipette

The accompanying sketch shows a form of pipette which has been found very useful by Sidney Born (*Journ. Ind. Eng. Chem.*, July, 1915) in his laboratory. It is made by fusing a stopcock and a piece of bent glass tubing to a pipette. The advantages over the ordinary pipette are:



MODIFIED PIPETTE

1. Safety—There is no danger of sucking up acid or dangerous liquids.
2. Ease of Manipulation—The stopcock insures tighter closing and greater accuracy than use of a finger.
3. Accuracy—The line of demarcation is level with eye when using.
4. The pipette can be carried around full without losing any liquid.

Macroscopic Etching of Steel*

The microscopic examination of steel by polishing the surface of small samples and etching with reagents has been brought to a far higher degree of excellence than has the technique of rendering visible on a large scale porosity, lack of homogeneity in composition, and other defects in steel that rolling or forging has rendered difficult to detect by ordinary optical inspection. Any improvement in the macroscopic methods would be very desirable, and such an improvement seems to have been found in etching the steel with molten zinc.

In samples described in this paper bars 10 in. by 1¼ in. by $\frac{5}{16}$ in. of openhearth iron, Norway iron, and openhearth steel, were suspended in the molten zinc of a 14-ft. galvanizing pump by means of iron wires. Later, some more samples of carbon tool steel and high-speed steel were added. On taking the samples from the molten zinc the mass of dross surrounding them could be broken off while still hot by blows from a hammer, and the coating of metallic zinc removed by immersion in dilute sulphuric acid, which does not affect the steel or iron so long as any zinc remains. High-carbon areas are rapidly eaten away by the molten zinc, and the method seems to afford a useful means of detecting such spots and, in general, lack of homogeneity in the surface. A few unsatisfactory trials have been made of etching nickel steel in molten tin, while the use of metallic mercury as an etching fluid and the extension of this method of testing to nonferrous metals are under consideration.

For Cleaning Laboratory Glassware, F. C. Mathers, writing in the "Chemist-Analyst," recommends a mixture of sulphuric and nitric acids, used at a temperature just too low to distil off HNO_3 or SO_3. Thick glassware should be placed in a cold solution and gradually heated. Enough nitric acid should be added to keep the mixture white or yellow in color. The combination is said to be superior to the bichromate-sulphuric acid mixture ordinarily used.

Correspondence and Discussion

The Pamlico Placer Field

In the *Journal* of Sept. 25, in the Mining News, under head of Inyo County, California, is a reference to the Pamlico placer field at Bishop. All the data are correct, but the Hawthorne mining district is in Mineral County, Nevada. Hawthorne, the county seat, is about 10 mi. west of Pamlico camp. The *Journal* may have received its item from Bishop, but with that post office address given it might be misleading, as there are other Hawthornes.

The Pamlico company has a new gallows frame, a gravel bin, also a 25-hp. gas hoist. The water for sluicing is brought 14 mi. from the southwest through a pipe line put in many years ago for a mill. About 25 men are now working on the two shifts. The placer gold is thought to have come from the Pamlico Hill, about one mile southeast of the present workings. Twenty-odd years ago ore reported to be worth from $100,000 to $150,000 per ton was taken from this hill. Some of the placer gold is very coarse. The surface was dry-washed years ago, but this is the first attempt to placer on a large scale. The company is down 120 ft. to bedrock. Nuggets as large as three troy ounces have been found.

Hawthorne, Nev., Oct. 9. W. P. Ross.

Chain Ladders Unnecessary!

On Oct. 10, four men were working in the bottom of the 1,780-ft. 3-compartment shaft at the Oro Hondo mine, near Lead, S. D. They had completed a round of holes and given the blasting signal to the engineer. The latter responded, and the fuses on the 12 charges were lit. The four men climbed on the bucket and gave the signal to hoist. For some reason this was not done as soon as they supposed it should be, and thinking something had gone wrong with the engine, the foreman jumped off the bucket with the intention of cutting the fuses. In climbing off the bucket he dropped his lamp and it went out. In the meantime the engineer, following the signal given him, hoisted the bucket with the three men on it.

When the bucket reached a place above the main bulkhead, the men on it gave the signal to stop, and climbed out on the timbers out of danger. They then signaled the engineer to lower the bucket, which he started to do. Before the bucket reached the bottom the man who was left there tried to climb the bell rope. In doing this he gave the one bell signal and stopped the hoist, at the same time breaking the bell cord. The engineer waited a reasonable length of time and not getting any signal hoisted the bucket to the station. Not finding any men on it he lowered it into the shaft, but before the bottom was reached the shots commenced. The three men that had gained the timbers climbed to the station by means of ladders.

The man at the bottom during this time realized that there was very little hope for him and crouched behind the lagging in one corner of the shaft. The 12 shots went off and completely covered him. There was little hope entertained by those above for his recovery, but an examination was immediately made and it was found that he was alive. Superintendent Talbot, with the aid of the night engineer, went into the shaft and after 30 minutes' work was able to get the man's head out. Some more hard work and he was uncovered and taken to the surface. It was at first supposed that it would be impossible to get him out before the water came up in the shaft and caught him. It was done, however, and an examination of the man after the accident showed that he was only slightly bruised on the side of his head. What might have proved a sad affair turned out without anyone being seriously injured. It is a lesson to those employed in shafts to have some other means of exit in case of necessity.

A chain ladder had been supplied the men with which to reach the first bulkhead, but it was several sets above and had not been lowered. Someone had been careless and had not followed instructions. There had never been any occasion to use the ladder before, but when the time came it was not in its place. Fortunately no one was injured, and from the occurrence a good lesson can be had, in that two methods of getting out of a shaft are absolutely necessary. S. E. B.

Lead, S. D., Oct. 16, 1915.

[One of which methods is, not to depend on climbing the bell rope. Even though the man was not killed the entire shaft crew should have been promptly fired. Why provide *two* methods of getting out when one reliable method provided was entirely disregarded?—Editor.]

The Cost of an Ounce of Gold

Our attention has been called to an interesting article in the *Journal* of July 10, 1915, entitled "The Cost of an Ounce of Gold," in which the author, Percy E. Barbour, states in the second paragraph that "the cost of producing an ounce of gold is not only not commonly known, but is not included in the report of any gold-mining company which has ever come to the notice of the writer."

We think the latter will therefore be interested to learn that the group of gold and silver mines in the Benkoelen district of Sumatra, under the direction of our Batavia principals, Messrs. Erdmann & Sielcken, have for some years past regularly published monthly reports in which the cost of production per ounce of gold is shown and even is subdivided into various branches of the working operations. Silver is also produced, but, being of secondary importance, is reduced to its equivalent value in gold for the purpose of calculation.

We inclose copies of the monthly report[1] of the mines Redjang-Lebong, Simau and Ketahoen for December, 1914, as published in Holland.

London, E. C., Oct. 5, 1915. Aschhoff & Co.

[1]These reports show the cost of gold at the three mines mentioned to have been respectively, $15.41, $11.26 and $27.34 per oz.

Dynamite Explosion at Granite Mountain Mine

BUTTE CORRESPONDENCE

At 1:20 o'clock, Oct. 19, the explosion of 13 boxes of giant powder at the collar of the North Butte company's Granite Mountain shaft, Butte, Mont., caused the instant death of 14 men and the serious injury of four others, two of whom have since died in the hospital.

Three times a week powder is sent down into the mine. The day of the accident was "powder day." The chippy cage upon which the powder is lowered does not run to the 2,800-ft. level and one car intended for that level, containing 650 lb. of dynamite, was held back to be lowered on the big cage coming up from the 2,800 level. Three loads of 13 boxes of powder each had already been lowered on the chippy, but before the big cage came to the surface to take the last box down to the 2,800-ft. level, the explosion occurred. While numerous theories have been advanced as to the cause of the explosion, the true one will probably remain a mystery, as the men handling the powder were all killed. The damage to the plant was comparatively slight. Manager Pope, of the North Butte company, after careful investigation stated that he had no theory whatsoever as to the cause of the explosion. The accident, which marks the worst tragedy in Montana's mining history, has been a severe shock to the community. Those numbered with the dead were all men highly esteemed by their employers and friends. Expressions of sympathy have reached the bereft survivors from all quarters.

The dead: James E. Blow, assistant foreman; Richard Gendle, electrician; George Larkin, nipper; John Winston, shift boss; Ed. Carlson, top carman; Robert Watson, shift boss; Ernest Watson, shift boss; Edwin C. Bray, shift boss; John McCauley, boss ropeman; Patrick J. Morrissay, shift boss; James Powers, nipper; William Danton, electrician; William Butcher, nipper; Phileas Blanchett, miner; Lacey Grisham, shift boss; John D. Leahy, nipper.

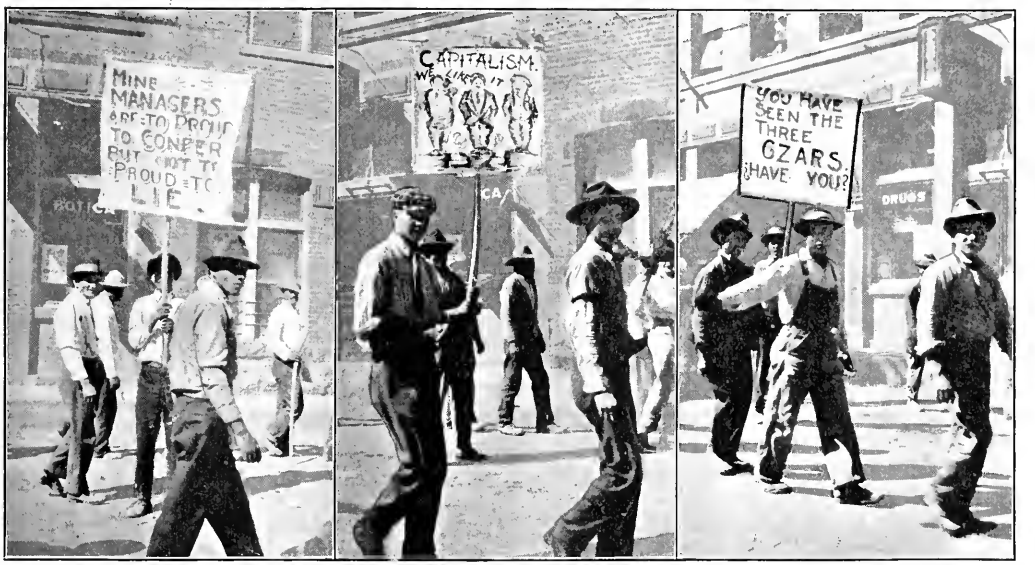
Seriously injured: Peter H. Brown, carpenter; William Vallentine, carpenter.

The Strike Situation in Arizona

SPECIAL CORRESPONDENCE

A condition of pacification reigns at Clifton, Morenci and Metcalf despite reports to the contrary. Physical damage to the extent of probably $125 has been done to the three camps, and many men have been driven from the districts and several injured.

Beyond a doubt the labor strike at the colossal mining camp has been one of the most remarkable in the history of similar events. It is different in that no strike-breakers have been brought into the camp by the operating com-



SOME TYPICAL BANNERS DISPLAYED BY THE STRIKERS DURING THE CHASE CREEK DEMONSTRATION

panies, no liquor has inflamed the minds of the strikers, no serious agitators have attempted a "stampede," and few have resisted the demands of the strikers, save by departing. There has been much of what journalists call "sob stuff" sent out from the Clifton-Morenci mining districts, but the true story of the situation is one of "watchful waiting."

The most disastrous results of the strike have been in disorganizing well-formed operating crews, stopping the movement of the wheels of industry, and the bitter taste left by the occurrence. As for the battles, dynamite destruction, starvation, etc., the accounts must be discredited.

Late in August organizers of the Western Federation of Miners entered the mining camps of Clifton, Morenci and Metcalf, Ariz., in which the Arizona Copper Co., Detroit Copper Co. (Phelps, Dodge & Co.) and the Shan-

ion Copper Co. operate. A mass meeting was held on Sept. 4 on the streets of Metcalf and again the following evening at Morenci. Banners with the inscription *Viva la Union* were displayed. The plaza was crowded with union sympathizers, and the opposition remained on the edge of the crowd. On Sept. 6, Guy Miller, organizer of the Western Federation of Miners, made an address in Clifton, after which a demonstration was held and *Viva la Union* again became the center of attraction. The crowd maintained order at all times. Mr. Miller then outlined the procedure of the Western Federation of Miners in Clifton and announced that upon the completion of organization a committee would present their demands to the officials of the three operating companies and stated that if, after a limited time, the demands were not met with, a strike would be called. Mr. Miller advised the men to conserve their savings and be prepared for the worst. Prior to this announcement many Federation organizers had gone over the Clifton labor situation, and it may be safe to say that plans for action were laid as far ahead as June. Mr. Miller's plans were followed out, and a committee requested an interview with the company managers. In answer, M. H. McLean, of the Detroit company, advised Mr. Miller that the Federation would not be recognized. J. W. Bennie, manager of the Shannon Copper Co. was in California when he received word of the requested committee meeting, and he wired his refusal. Normal Carmichael was also away at the time, but took a stand similar to that of McLean and Bennie.

On Saturday night, Sept. 11, a strike was ordered, and by 3 o'clock Sunday morning not a wheel moved in any of the mines, mills and smelteries. With the striking miners all other union employees walked out in sympathy. Guards were stationed for the protection of the company's property and pickets placed by the strikers. It was then announced that the men would demand from the companies the same wage scale as paid at Ray, Ariz. The company officials then stated that they would meet a committee of the workingmen as such, but not as members of the Western Federation of Miners. No effort was made to operate any part of the mines, mills or smelteries, and no strike-breakers were imported. This was one of the wisest moves during the entire situation. The next move made by the companies was to turn over all their property to the protection of Sheriff James Cash of Greenlee County, requesting him to protect it from any violence, and they withdrew their own watchmen. Sheriff Cash appointed about twenty deputies whom he placed over the property.

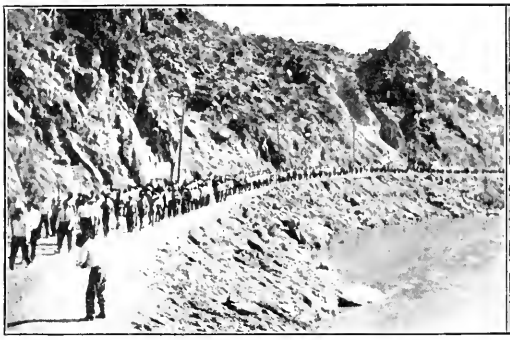
On Tuesday, Sept. 28, Governor G. W. P. Hunt arrived in Clifton shortly after 10 o'clock from Phœnix. From then on whatever violence was to take place made itself known.

On Saturday night, Oct. 2, Managers Carmichael, McLean and Bennie decided to leave Clifton, and went to Lordsburg, N. M., where they were arrested on a charge of being fugitives from justice. J. W. Bennie stated that it was his belief that the sheriff was planning to place them (the three managers) in the county jail, fearing violence of the strikers. Rather than be placed in the hands of the county, they left camp on a special train. Under-Sheriff Joe Larrieu was in Lordsburg and was informed of the departure of the managers. He made a complaint on a fugitive-from-justice charge and the three officials were placed under arrest by the sheriff of Grant County, New Mexico. At midnight Sheriff Cash arrived by automobile and held a warrant charging the managers with inciting a riot, presumably for leaving the camp. The justice of the peace dismissed the case, and the men left for El Paso, where they established headquarters in the Hotel Paso Del Norte.

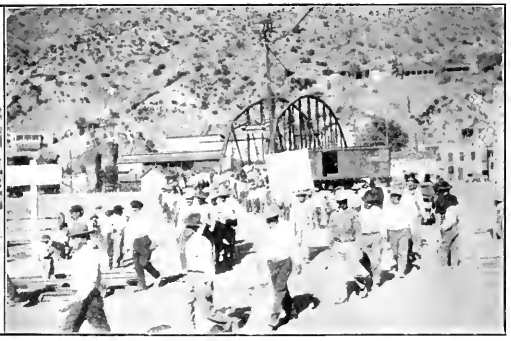
The violence that ensued in Clifton comprised the following incidents: The engineer and fireman who brought the managers to Lordsburg were severely beaten up by the strikers, as were several other workmen; windows in the Arizona Copper Co.'s office and drug store were broken; the engineer at the light plant was overpowered and the lights turned off; and a charge of dynamite was reported to have been set off at Morenci. A great many persons were ordered out of camp and many left, some forming a colony at Duncan, Ariz. Others went to other mining camps in the Southwest. Parades were held, and banners bearing glaring inscriptions were brought on the scene.

On Oct. 4 about 40 members of the Arizona National Guard were sent to Clifton by Governor Hunt, and later a request was made by the sheriff and others for more troops, which were sent. The militiamen camped near the Arizona Copper Co.'s smelting plant and at the courthouse.

Moyer left Clifton on Oct. 6, to consult with Governor Hunt in Phœnix. He said that the Federation would withdraw all requests for recognition and all that it asked was a decent wage scale for the employees. He considered the requests of the managers incoherent in regard to the "dominant influence." He agreed that if the presence of



PARADE OF 5,000 MEXICAN EMPLOYEES AT CLIFTON



THE DEMONSTRATION ON THE PLAZA AT CLIFTON

himself or any of the Federation organizers retarded a settlement they would be only too glad to leave the district. He gave the solution as being in a meeting of the managers with the employees.

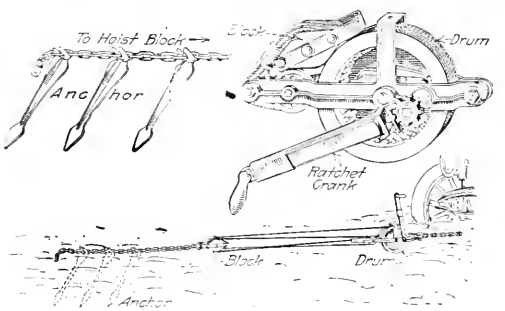
Several attempts have been made to send committees to El Paso to meet with the managers, but only one has been accepted. It consists of Hollingsworth, Hughes, Palacios, Garcia and Daley.

The latest communication from El Paso contains the information that at the conference between the managers and the committee of employees, they had not been able to agree. The managers stipulated that the Western Federation of Miners must be eliminated and that the employees must return to work under the former scale of wages. No other conditions would be considered. The employees' committee, not being willing to accept these terms, returned to Clifton.

A Little Thing with a Big Pull

An ingenious piece of mechanism devised for the automobilist to enable him to pull himself out of a hole looks as if it would be a very handy contrivance to have around a mine.

The device is known as "Pull-U-Out," and is in effect a miniature chain block, and is simplicity itself. A substantial winding drum, with gears inside, engaging a small bronze gear on the end of a long ratchet crank, furnishes the pull. At the other end of the tackle is a small double block; 40 ft. of steel cable, with a capacity



THE PULL-U-OUT DEVICE

of 5,000 lb. is used. Two 7-ft. pieces of light-weight chain, with hooks on each end, complete the outfit.

In order to furnish an anchor where there is no stump or fixed object to tie to, three light-weight steel stakes are provided with each "Pull-U-Out" outfit. These are to be set in the ground, tandem fashion, about a foot apart, leaning toward the object to be pulled—not away from it, as one would suppose. When driven in in this fashion and the chain fastened to the three stakes, it is claimed that 50 men could not pull them out with a side pull, but that when the tension is released they can be easily pulled up on the same angle at which they were driven. The manufacturers say "the device itself is clever, but these three stakes are more than clever."

Underground, this little device ought to prove of immense advantage many times. The handling of big timbers in stopes would be much facilitated or the handling of timbers in a raise or winze.

The handling of the sinker pump when shaft sinking, or the placing of additional lengths of water column, especially when the size is large, furnish other applications for this device. In fact there are so many ways in which this device can be used to advantage around the mine, both on top and underground, that it ought quickly to become the miner's friend. Its portability is as great an attraction as its pulling power.

The complete outfit is sold by the Pull-U-Out Sales Co., 2018 Market St., St. Louis, Mo., for $15. The accompanying sketch shows this interesting, cheap and promising little device.

British Prize Court Decides Against Merton & Co.

The British prize court, on Oct. 6, 1915, decided against Henry R. Merton & Co. in the matter of freight charges on 6,710 tons of zinc concentrates seized on the steamship "Bilbster." The cargo was consigned by the Australian Metal Co. to Henry R. Merton & Co., of London. The latter had advanced £5,000 to the shipowners on account of freight charges of £7,546 and brought an action against the Crown for a refund of this freight payment on the seized cargo.

The Crown contended that the concentrates were "enemy goods," and this was admitted by Merton & Co., as they had become the property of Beer, Sondheimer & Co. The shipowners, meantime, put in a claim for the full amount of their freight. An award of the balance, £2,546, was allowed the shipowners by the court, but the claim of Merton & Co. for refund of the £5,000 was disallowed on the grounds that they had acted as agents for the Metallgesellschaft of Frankfort on Main and that the money had been paid to the shipowners on behalf of the German firm with the idea of retaining the goods for the German owners.

Another zinc cargo of about 5,000 tons, shipped by the Australian Metal Co. prior to the war, on the S.S. "Manningtry," was condemned as being practically the property of the Metallgesellschaft. It was claimed by the Australian Metal Co., Henry R. Merton & Co., the Cie. des Minerais, of Belgium, and another firm.

Australian Wolframite and Molybdenite Situation

The Federal Government of Australia has recently issued a proclamation in the molybdenite, scheelite and wolframite districts of Australia, according to the *Australian Statesman and Mining Standard*. The following is an abstract of this proclamation:

The Commonwealth Government has entered into an arrangement with the Imperial Government for a period of 12 months, to acquire, for the Imperial authorities, all the molybdenite, wolframite and scheelite produced in Australia. For the purposes of this arrangement the Commonwealth Government has appointed Dalgety & Co. as its agents. The price payable to the producers at the following places is to be not less than the following amounts: Wolfram Camp—Wolframite or scheelite, 45 2; molybdenite, 90 10. Bamford, 45 6, 91 1. Cairns—F.o.b., 46 6, 91 10. Townsville—F.o.b., 47 4, 92 6. Port Darwin—F.o.b., 47 2, 92 8. Melbourne—Ex-rail or ship, 48 1, 93 10. Sidney—Ex-rail or ship, 48 1, 93 10. Prices at other fields, if any, will be fixed on a similar basis. Provision has been made for the compulsory acquisition of any of these minerals which are held back, and this arrangement supersedes all existing contracts for the sale and disposal of these minerals, but does not otherwise interfere with the position of agents or their arrangements with producers.

Editorials

The Situation in Spelter

The continued strength of the spelter market in the face of steadily increasing production and a diminished consumption for domestic peaceful purposes has been a matter for surprise among students of the situation. A few months ago it was the fashion to prophesy that the trend of spelter would be steadily downward but time has passed and the expected has not happened. This does not, however, prove the prophets wrong. It is a common mistake to misgage the time in which clearly discerned factors are going to develop.

Thus, in the case of spelter itself, when the war began, the first idea among American zinc producers and merchants was that there would be a great foreign demand for our spelter. Such a demand did, in fact, appear soon, creating what was then considered a great boom in spelter, the price rising to something like 6c., but when this demand slackened there was a relapse and pessimism reigned again. By December the great boom in spelter that had been forecasted in August was forgotten. It began in January, however, and then soon demonstrated itself as being the real thing.

A little while ago attention was focused on the additions to smelting capacity that were so extensively and so rapidly being made. The deduction was promptly drawn that this would result in a collapse in the price for spelter. When that failed to happen right away, the idea seemed to be forgotten. The price for spelter rallied, and no longer were lists published showing how many new retorts were going to become productive in October, etc.

Renewed attention is drawn to this, however, by the actual beginning of smelting at certain of the large new plants, namely, those at Donora and at Kusa. The Donora plant was put in operation on Oct. 21, just four months and ten days after construction was commenced. In antebellum days 18 months would have been regarded as a conservative estimate of the construction period of such a plant. The ratio of 18 to 4⅓ is not, however, a precise statement. Donora at present is still far short of the point where it may be regarded as complete, although it has reached the point of producing some spelter.

Besides the new zinc-smelting plants that have previously been mentioned, several other little plants are going up in a variety of places. This is natural when spelter rules so high and ore relatively so cheap, and in the end such increase of capacity will of course bring about its natural result. In considering why a weaker tendency in the spelter market has not yet become manifest, it must be borne in mind that during the extraordinary boom that prevailed from about the beginning of April to the end of July, a large part of the expected production of the smelters during the last quarter of the year was sold. Consequently, smelters are still busy in making deliveries on their old contracts, and unsold stocks of spelter have not yet begun to accumulate to any considerable extent, although there has been, without any doubt, a certain accumulation during the last six weeks. In the meanwhile the market has been supported by a renewed and extraordinary foreign demand, although this has not attained any very great proportions. Certainly there has been nothing of late to cause a revision of opinion as to what is ultimately going to happen in the spelter market.

Anaconda's Campaign for Safety First

A recent number of the *Anode,* one of the monthly magazines published by the Anaconda Copper Mining Co. in furthering its campaign for the lessening of accidents in its mines and works, contains some interesting data for the first semester of 1915. The most important part of these is a matter of pure statistical practice. The accident rates reported by state authorities are computed by dividing the number of accidents—say the fatal ones—by the number of men employed on the average. Let us say that in the mines of Butte there were 52 men killed in a year and the average number of men employed was 13,000. The fatality rate would be 4 per 1,000. It has long been recognized that this is nothing but a rough method. The divisor is largely a matter of guesswork, while even if it were correct there would enter into consideration the probability—nay, certainty—that all of the men do not work all of the time. This tends to make the division too high and the quotient too low. The correct basis is of course the number of accidents per 300 thousand man-days; that is, per thousand men if all worked 300 days—assumed to be a full year. The statisticians of the United States Bureau of Mines are trying to introduce this system. It would be rendered relatively easy if all of the big mining companies should adopt it.

The Anaconda company has adopted it in a way, reporting its "fatal and serious" accidents upon a basis of 10,000 shifts. The idea of this is correct, namely, to put things on a definite basis, but the method of doing it is rather unfortunate, preventing as it does the comparison of its figures with any others, for two reasons—the divisor and the classification both being odd.

Respecting the matter of classification, "What is a serious accident?" On this subject the committee of consulting engineers that made a report on "Rules and Regulations for Metal Mines" for the United States Bureau of Mines said: "To define properly a 'serious' accident is somewhat difficult. About the only feasible method of differentiating 'serious' from 'minor' accidents is on the basis of the length of the period of disablement. The committee has made the dividing line 14 days. This is a figure commonly so taken in reporting mine accidents and corresponds with the length of time elapsing before an injured employee receives compensation, according to most of the compensation laws of which the committee has knowledge."

In reporting accidents the one sharply dividing line is that between fatal accidents and all others. If a man be killed, that is certain and there is no question of making fine or arbitrary distinctions as to whether the accident was serious or not. But the lumping of fatal and serious accidents leaves us quite in the dark.

In the first six months of 1915 the average of fatal and serious accidents in the Anaconda mines was about 1.80 per 10,000 shifts; or we may estimate about 1.80 per 400 men per month, assuming 25 man-shifts per month or 4.5 per 1,000 men, and the rate per annum would be 12 times as much, that is, 54. However, this figure is not comparable with anything else that we know of. In the first quarter of 1915 the average of fatal and serious accidents in the Anaconda mines was 1.92 per 10,000 shifts per month. In the second quarter it was 1.69, a gratifying reduction, but the periods are too short to permit of any reliable deductions respecting the influence of the "safety-first" movement.

The same number of the *Anode* contains some interesting notes about the Washoe mine, one of the Anaconda's collieries. Loose rock on the sides of the entries and roadways are to be removed regularly by the company—a commendable thing. It having been observed that in hoisting men at end of shift they would jump off the cars before the latter had come to a stop, a gate has been placed at the main exit of the shaftway, which is opened only when the trip has come to a stop. This also is a good thing. Many shaft accidents result from the men's crowding on the cage in excess of the regulation number, from skylarking on the way up and from disobedience of rules generally.

Standardization of Data

The Mining and Metallurgical Society of America is undertaking, with the aid of a distinguished committee, work in the direction of the standardization of technical definitions and practice. The Institution of Mining and Metallurgy has already accomplished important work of this nature, and some attention to the subject has been given by the Canadian Mining Institute. The committee of the Mining and Metallurgical Society lately made its first report, which was to a large extent a review of previous reports by the Institution of Mining and Metallurgy, the idea being that the three organizations shall proceed on the same lines.

This is an important piece of work, tending toward precision of statement and clarification of ideas. Whenever a technical man gives any data, everybody should be able to know just what he means. The chances for confusion are greater than many persons realize. Thus, one zinc smelter may refer to a certain works as having four furnaces and another may tell of the same works having eight furnaces. The latter upon interrogation would explain that the works had eight furnaces, but only four blocks.

Even the definition of a word, commonly dismissed as merely a concern of the lexicographer, may become a matter of great consequence. Thus many thousands of dollars were spent a few years ago in tariff litigation that hinged on the definition of calamine, notwithstanding the fact that a long time previously it had been pointed out that trouble was likely to occur owing to the confusion about that name that existed. This question has not yet been cleared up, a change in the tariff law having removed the acute necessity for settling it.

These are merely examples. They show that the more that uncertainties can be eliminated the better will things be. Such work as the Mining and Metallurgical Society and the other organizations may do in this way will therefore be very helpful.

Zinc Smelters' Profits

Contrary to the popular idea, the zinc smelters do not always make money, no matter how extensively they "rob" the miners whose ore they buy. In fact, a good many of the ventures in zinc smelting have been disastrous to those who put their money into them. The extraordinary turn of the tide in 1915, however, has enabled almost everybody to make money in smelting, no matter how imperfect his plant and methods, and several of the concerns that previously were in a bad way have been enabled not only to get their accounts into good shape, but also to arrive in a position for the payment of dividends.

Thus the American Zinc, Lead and Smelting Co., which about a year ago was practically a derelict with neither money nor credit, has paid off its indebtedness of about $1,750,000 and ere long will probably be considering the payment of a dividend. The Lanyon Starr Smelting Co., which for a number of years has not earned enough to pay dividends, even on its preferred stock, recently declared a dividend of 21% on that class of stock, to provide for all cumulative dividends up to July 1, 1915.

Zinc smelting has been very profitable during 1915, but it has been the big zinc-mining companies, like the New Jersey Zinc Co., Granby Mining and Smelting Co., Butte & Superior Copper Co. and Interstate-Callahan Mining Co., that have earned and paid the speculator dividends. The earnings of the American Zinc, Lead and Smelting Co., moreover, are derived to a greater extent from its Mascot mines than from the smelting branch of its business.

Copper Mines in Serbia

A good deal of nonsense is being printed in the daily newspapers about the great supplies of copper that the Teutonic allies are going to gain when they have conquered Serbia. The copper mines of Serbia are, indeed, a little more important than the alleged copper mines of Poland, but they have never been largely productive. The only copper-producing concern is the company owning the Bor mines, which previous to the war produced six or seven thousand tons of copper per annum.

The shortage of ships, previously a matter of great concern, was rendered more acute by the blockade of the Panama Canal. A large number of vessels waiting at the entrances were obliged to hoist anchor and steam around Cape Horn, thus depriving commerce of their carrying capacity for two or three months. Several cargoes of Australian zinc ore were thus caught. The ships bringing it have been sent around Cape Horn, excepting one which was ordered to San Francisco, whence the ore is to be brought overland to the smelters.

BY THE WAY

Dispatches of this week again report that Villa has taken possession of the Chihuahua smeltery of the American Smelting and Refining Co. and will smelt some of the confiscated silver-lead ore that the company has declined to treat, "owing to the absence of its technical staff."

⁂

At the meeting of stockholders of the Southern Aluminium Co. in New York on Oct. 23, it was voted to dissolve the corporation. Action of the Paris directors is now being awaited. It has been rumored that L'Aluminium Française may take over the American project at Whitney, N. C.

⁂

Death Valley Scotty, the mysterious man who had the whole Western country guessing in the days of the Goldfield excitement, has again shown up, this time at San Bernardino. He carried with him the usual bag of high-grade and this time reports that his new find is located at Twenty-nine Palms, in the Colorado desert.

⁂

The new zinc-smelting plant that has been constructed at Donora, Penn., is variously described as being of the United States Steel Corporation, of the American Steel and Wire Co. and of the Edgar Zinc Co. This explanation is that the United States Steel Corporation owns the American Steel and Wire Co., and the latter owns the Edgar Zinc Co. The actual management of the Donora plant is vested in the officials of the Edgar Zinc Co., and the ore contracts, etc., are made in the name of that company.

⁂

Following the *Journal's* custom, the final standing of the chief baseball leagues is given below for the benefit of the subscribers in the "jungle":

AMERICAN LEAGUE	W.	L.	Per Cent.
Boston	101	50	0.669
Detroit	100	54	0.649
Chicago	93	61	0.604
Washington	85	68	0.559
New York	69	83	0.454
St. Louis	63	91	0.409
Cleveland	57	95	0.375
Philadelphia	43	109	0.277

FEDERAL LEAGUE	W.	L.	Per Cent.
Chicago	86	66	0.566
St. Louis	85	67	0.565
Pittsburgh	86	67	0.562
Kansas City	81	72	0.530
Newark	80	72	0.527
Buffalo	74	78	0.487
Brooklyn	70	82	0.461
Baltimore	47	107	0.305

INTERNATIONAL LEAGUE	W.	L.	Per Cent.
Buffalo	86	50	0.632
Providence	85	53	0.616
Toronto	72	67	0.518
Rochester	69	69	0.500
Montreal	67	70	0.489
Harrisburg	61	76	0.445
Richmond	59	81	0.423
Jersey City	52	85	0.380

NATIONAL LEAGUE	W.	L.	Per Cent.
Philadelphia	90	62	0.592
Boston	83	69	0.547
Brooklyn	80	72	0.527
Chicago	73	80	0.477
Pittsburgh	73	81	0.474
St. Louis	72	81	0.471
Cincinnati	71	83	0.461
New York	69	83	0.454

The post-season series, Boston vs. Philadelphia, was won by Boston, 1-3; 2-1; 2-1; 2-1; 5-1.

⁂

It is only a few years since smelting plants were being closed because they were distributing sulphuric acid over surrounding farms. Now comes the announcement that the smoke question is to be settled by the production of sulphuric acid and its application to the alkali lands of the Western States. At the engineering convention in San Francisco, Dr. C. B. Lippman, of the University of California, announced that apparent beneficial results have been obtained by the application of sulphuric acid to alkali soils. Views were presented, depicting crops grown on test plots that had received from 2½ to 7½ tons of sprayed sulphuric acid to the acre, the ground previously having been unfit for agricultural purposes on account of alkali salts. There is much alkali land around certain smelting plants in the West, and the smelters would welcome a profitable outlet for the sulphuric acid that they could produce. Thus it may be proved to them that "damage" as well as dirt is merely "matter out of place."

⁂

Bethlehem-Pennsylvania Deal

A week ago it seemed certain that the controlling interest in the Pennsylvania Steel Co. would pass to the Bethlehem Steel Co., as then stated. There seemed to be no doubt that Mr. Schwab's bid would be accepted by both the Pennsylvania Co. and the Reading Iron Co., whose holdings of the Pennsylvania Steel stocks constitute a very large majority. Indeed, it was stated on the best authority that Schwab's bid was satisfactory to the Pennsylvania people, and that it only remained for the Reading Iron board to approve of the transaction.

An unexpected obstacle has arisen, however. As is well known, William H. Donner, president of the Cambria Steel Co., has for some time held an option on the Pennsylvania Steel stock at a fixed price, with the further provision that he should have the first call on the stock in case a higher price should be offered by anyone. It now seems that Mr. Donner has given notice that he will meet the Schwab bid, and the transfer is uncertain pending further negotiations. It is said that H. C. Frick is backing the Donner party.

⁂

Utah Potash Production Begins

SALT LAKE CORRESPONDENCE

The production of potash on a commercial scale in Utah has been started. The plant of the Mineral Products Co., at Marysvale, began operating in its entirety for the first time Oct. 19. The roasters had been warmed up and tried out some time before this, and the plant was ready by the middle of September, but on account of the reconstruction of the tramway from the mine to Cottonwood Cañon, operations were delayed until this week. The capacity of the first unit, which is complete in itself, is 100 tons a day. Other units will probably be added.

The alunite contains about 11% of potash. It is roasted to form a soluble potassium sulphate, and this is leached out with water and evaporated to a solid salt from the solution. From 25 to 30 tons of potassium sulphate running over 90% will be produced daily, and the first carload shipment, according to Charles E. Macdowell, vice-president of the company, will consist of 93% concentrated sulphate of potash, and will be shipped some time during the week to a firm in Florida. The percentage is higher than that of the German product, which seldom ran above 90%. At present the output will be hauled 6 or 7 mi. to the railroad by motor trucks, but a side track will be built to the plant by the Denver & Rio Grande R.R., in the near future. Pure alumina is obtained from the residue of the alunite after leaching and is a valuable byproduct.

PERSONALS

Whitman Symmes, of Virginia City, Nev., has been in New York.

W. A. Wilson, mining engineer, has removed his offices to the Dooly Block, Salt Lake City, Utah.

Ernest J. Ristedt, chemist for the Old Dominion Copper Co., Globe, Ariz., has been paying a brief visit to his former home in Denver.

H. V. Dardier, accompanied by an engineer representing the Vickers-Maxim Co. of London, has been investigating nickel deposits near Fond du Lac, Manitoba.

A. W. Soderberg has been appointed chief mechanical engineer of the Homestead Steel Works of the Carnegie Steel Co. in place of R. H. Stevens, who has gone to the Midvale Steel Works.

Roy J. King, of Tonopah and Grass Valley, who spent August and September in Alaska and British Columbia, has returned to the States, and now is in Oregon on professional business.

F. C. French sailed from Seattle for Alaska on Sept. 14. He will be constructing engineer on the reconstruction and enlargement of the plant of the Beatson Copper Co. at Latouche, Alaska.

F. E. Marcy has resigned as local manager of the Mine and Smelter Supply Co. at Salt Lake City. He will devote his time to the sale and manufacture of the Marcy mill, which is controlled by the company.

C. E. Addams, for some time connected with the De Beers Consolidated Mines in South Africa, and later with the Ray Consolidated, has been appointed general manager of the Ray Hercules Co. in Arizona.

Jesse Lee Jones, who was chosen president of the American Institute of Metals at the recent annual meeting, is chief chemist and metallurgist of the Westinghouse Electric and Manufacturing Co. of Pittsburgh.

J. J. Warren, president of the Kettle Valley Ry., has been added to the board of directors of the Consolidated Mining and Smelting Co., of Canada, operating Trail, B. C., smelting works, and has been appointed managing director.

Thomas M. Skinner, Jr., having finished the chemical work in which he was engaged at Keeler, Calif., pertaining to the alkali waters of Owens Lake, has returned to Colorado and is temporarily engaged with the Empire Zinc Co. at Denver.

T. Hirabayashi, H. Nakamuta and S. Nakagawa, mining engineers representing the Japanese government, recently spent one week inspecting ore- and coal-dock facilities in the Duluth-Superior harbor, also the plant of the Minnesota Steel Co., near Duluth.

F. O. Williamson, who represents the Hardinge Conical Mill Co., T. L. Smith Co. and Smith Engineering Works, in Chicago and adjacent territory, is taking an extended trip through the Western mining districts, on his way to San Francisco.

H. G. Moulton, who has been with the firm of Eugene Meyer, Jr., & Co., of New York City, as consulting mining engineer for the last seven years, has recently been appointed by the Public Service Commission consulting and inspecting engineer on underpinning and excavation for the new subways in New York.

Dr. James Cole Roberts, in charge of the United States Bureau of Mines Rescue Car No. 2, with headquarters in Denver, has accepted appointment as professor of safety and efficiency engineering, the department recently authorized by the trustees of the Colorado School of Mines as a tribute to the late Dr. Joseph A. Holmes. Dr. Roberts is well fitted by experience and personality for this chair. Fifteen years ago he resigned the professorship in metallurgy in this same institution.

OBITUARY

Henry Lamy, of Paris, France, a graduate of the Massachusetts Institute of Technology in the Class of 1913 in mining engineering, was killed recently while serving in the French Army in Champagne. He was a son of Lucien Lamy, of Paris, a prominent metal broker.

George H. Abeel, whose death on Oct. 13 was briefly noted last week, was 53 years old, and had had charge of iron mines in Michigan and Wisconsin for 27 years. For a number of years he was in charge of the operations of Oglebay, Norton & Co. on the Gogebic Range. He was an active member of the Lake Superior Mining Institute from its start and was vice-president in 1913-14. He leaves a widow, a daughter and two sons, both of them mining engineers.

SOCIETIES

Texas School of Mines—Fall term has opened at El Paso with very encouraging enrollment. Special attention will be given to assay department this year.

Teknik Club—At the regular meeting of the club in Denver, Oct. 12, Mr. Eastman, of the Bureau of Mines, spoke on "Some Experiments with Basic Lead Compounds."

Utah Society of Engineers—The regular monthly meeting of the society was held in Salt Lake City Oct. 15, when W. H. Trask, Jr., deputy superintendent of the Utah Power and Light Co., gave an address on the good results to be had through the irrigation of crops by pumping systems.

American Chemical Society—The Pittsburgh Section held a joint meeting with the American Electrochemical Society at the University of Pittsburgh, Oct. 21. A large number of members attended and heard an address by F. T. Snyder of Chicago, on the use of electric furnaces. A number joined in the subsequent discussion. O. G. Schleuerderberg, chairman of the local section of the Electrochemical Society, presided. At a dinner at the University Club, before the meeting, the diners heard an address by Dr. F. C. Phillips of the University, who suggested that some technical society undertake to purchase and preserve the old Northumberland County home of Priestley, the chemist who discovered oxygen. The home is now in danger of destruction.

American Institute of Mining Engineers—The Montana Section held its semi-annual session Oct. 8, at the Silver Bow club rooms, in Butte. Between 60 and 70 members attended the meeting which was presided over by Vice-Chairman J. L. Bruce. A very enjoyable dinner preceded the technical session, at which J. A. Grimes read an interesting outline of a paper now being prepared by himself and Mr. Billingsley, entitled: "Mines in the Boulder Batholite." The paper will appear later on in the "Transactions" of the Institute. The reading of the paper was followed by a lively discussion of the theories advanced by the authors and based on facts observed in the mines so far visited by them in the district affected by the batholite. The authors are members of the geological department of the Anaconda Copper Mining Co.

American Iron and Steel Institute—The program for the meeting of the Institute at Cleveland, Ohio, Oct. 22 and 23, was: Address by President Elbert H. Gary. "Cleveland and Its Industries." Name of author, a Cleveland member, to be announced later. "Electric Furnace for Heating Billets, Castings, Etc." By Thaddeus F. Baily Alliance, Ohio. "Modern Methods of Burning Blast-Furnace Gas in Stoves and Boilers." By Ambrose N. Diehl, Duquesne, Penn. "The Development of Alloy Steel for Commercial Purposes." By Edgar D. Rogers, Canton, Ohio. "Under-Advertising of the Steel Business." By George H. Jones, Chicago. "Recent Developments in Sintering of Iron Ores." By Bethune G. Klugh, New York. "Casting Steel Ingots." By Henry M. Howe, Columbia University, New York. Moving pictures (evening). National Tube Co. and American Steel and Wire Co. The Cleveland committee arranged for plant trips and various forms of entertainment for the members on Saturday following the regular meeting day

Intermountain Lehigh Club—In Salt Lake City, Oct 16, a dinner was given to Dr. Henry Sturgis Drinker, president of Lehigh University, by this club, which is made up of Lehigh alumni in Utah and neighboring states. At the dinner Dr. Drinker spoke of the increasing interest taken in modern institutions in the personality of the student, and of the duty incumbent on such institutions to use their influence in aiding in the formation of national and local movements looking toward the public good. Touching on conservation, he said that in taking wise and broad measures to utilize best our natural resources, our woods, our mines, and waters, the need was not so much to withdraw and set them aside for the use of future generations, as to be sure they were not wasted in their use by the present generation, letting them be utilized following the natural laws of supply and demand, with due regard to the essential factor that private capital will never venture into the proper broad economic exploitation of these resources, without the assurance of a sufficiently permanent tenure to insure an adequate return for investment

Editorial Correspondence

SAN FRANCISCO—Oct. 21

The State Industrial Accident Commission has prepared a pamphlet for free distribution containing the amended Workmen's Compensation, Insurance and Safety Act. The most important of the amendments which went into effect Aug. 8, 1915, other than those relating to procedure are: (1) Extending the benefits of the law to cover injuries received in the course of employment, whether accidental or otherwise; (2) empowering the commission, in special cases, to extend the time during which medical and surgical benefits shall be furnished to injured employees; (3) providing that, in case of the loss of an eye or limb, an artificial member shall be furnished by the employer; (4) making it a misdemeanor for an employer to exact or receive from any employee any contribution, or make any deduction from his earnings, to cover any part of the cost of treatment or compensation provided by the Act. There are other changes from the original text, all of which are of general interest. Copies of the pamphlet may be had on application to the commission, 525 Market St., San Francisco.

Oil Land Suits instituted by the Federal Government involving valuable lands in Kern County are to be tried in the U. S. District Court at Los Angeles. These suits are similar to others that have been tried involving lands which are alleged to have been withdrawn from entry by the withdrawal order of President Taft, Sept. 27, 1909. The present contention of the Government is that the defendants developed oil in the land after it was withdrawn, and asks that the Government be found the owner in fee simple and that the defendants be ousted from any right they may assert; and that injunction be issued restraining defendants from further development, an accounting be had and a receiver appointed. The following named companies and corporations are defendants: Thirty-two, California Midway, Buick, Associated, Standard, California Natural Gas, and J. M. McLeod. The land is situated in section 32, and is stated to be of great value, but the value is not stated.

Midway-Sunset Oil Suits to have been tried by Judge Bledsoe in the U. S. District Court at Fresno on Oct. 18 may be assigned to another judge of the same court on account of disqualification of Judge Bledsoe who is a stockholder in one of the companies defendant. In a previous case tried, this judge made such fair rulings in favor of the Government that the Federal attorneys expressed willingness that he proceed in the present trial; but attorneys for the defendants are inclined to the notion that the cases should be tried by a jurist upon whom there can rest no shadow of bias or prejudice. These suits were brought by the Government to recover 40,970 acres of oil land in the Midway-Sunset field in Kern County, which is part of a total area of 154,197 acres included in six several suits, a part of which are to be tried in the Federal Court in Los Angeles. The land was filed on and patents issued to the Southern Pacific Co. under the act of congress of 1866 upon representation that the land was not mineral in character. The Supreme Court, however, has upheld the theory of the government geologists that petroleum oil is a mineral product. The only question now involved is whether the Southern Pacific entered upon the land in disregard of the withdrawal order of President Taft of September, 1909. That order has been upheld by the Supreme Court.

DENVER—Oct. 21

The Miner who Impounded the Water pumped from the Golden Cycle mine, Goldfield, Colo. (Cripple Creek district), collected the resulting slime and shipped his air-dried product made a close approximation to the proverbial "getting something for nothing." No other treatment was given this stuff, there was no royalty paid anybody, and the miner asserts that he has received more than $2,000 from his small shipments.

The Vanadium Mill at Vanadium, formerly Newmire, San Miguel County, Colo., controlled by the Primos Chemical Co., is operating full capacity, treating from 125 to 150 tons daily. The ore is mostly from the company's mines in Bear Creek Cañon, which have been extensively developed by several miles of tunnels and drifts. Recently diamond drilling showed the ore bed to extend westward below the grade of the cañon, and a shaft was started to cut it at 700 ft., but at about 300 ft. the flow of water was so strong that shaft sinking was for the time suspended and an incline is being driven to reach the ore. The company is also mining from its claims near Saw Pit and shipping to the mill. It is reported that the capacity of the plant will soon be greatly enlarged again.

A Real Mining Revival is taking place in Boulder County. Prospectors and miners are reaping a harvest after several years of very "slim pickings." Attractive prices for tungsten ore have led to the opening up of many prospects that were located for gold and now are found to carry appreciable amounts of the black metal. In some instances, tungsten was known to occur in these properties, but was not developed commercially. It is now believed that the presence of tungsten in some of the gold ores of this county has been responsible for the low concentration accomplished and that much of the concentrate shipped for years may have been more valuable for its unrecognized tungsten content than for its gold. The heretofore recognized tungsten area tributary to the town of Nederland has been found to have competition in an area to the northeast of that town nearer the city of Boulder. The Boulder County Metal Mining Association is arranging an excursion from Denver to Nederland to give curious persons opportunity to witness the mining of tungsten.

SALT LAKE CITY—Oct. 22

The Old Dump at the Horn Silver Mine at Frisco, estimated to contain 175,000 to 200,000 tons of tailings, is to be utilized. The Caldo Mining Co., backed by Eastern capital, was formed a short time ago to take over a lease on the dump, and finance the building of a mill of 200 tons daily capacity. Construction is in the hands of the General Engineering Co., of Salt Lake, which also has charge of the management of the property. The principal value of the tailings is in silver, with some zinc. It is hoped to have the mill completed before the end of November.

Progress Is Being Made in the Construction of the Tintic Milling Co.'s new plant at Silver City. Foundations, retaining walls, and floors of the mill are completed, the bins are almost finished, and the steel work is being erected. The crushers and rolls are in place. There are to be three Holt-Dern roasters of 45-ton capacity, of the same type as used in the mill of the Mines Operating Co., at Park City, and one Christensen roaster, which was intended for the Knight mill, at Silver City, destroyed by fire not long ago. The cost of the mill will be about $150,000. The company has taken a lease on the old Eureka mill dumps, and on other dumps and low-grade ore in the district. Sixty-five men are employed on construction, and it is hoped to have the plant in operation soon after the first of the year.

The Facilities for the Treatment of Low-Grade Ore and dumps long idle, have been much increased by new reduction mills and flotation plants recently constructed or still in the process of construction. In some cases companies have been organized with a view to utilizing dumps at individual mines, and in others custom milling plants have been established. Also individual mines like the Utah Apex at Bingham, the Daly-Judge and Silver King Coalition at Park City have added or are adding flotation plants to their milling equipment. The Big Four Leasing Co.'s mill, at Atkinson in the Park City district, has been in operation for several weeks on tailings accumulated below the town, from the various mines of the camp; the capacity is 200 to 300 tons. The Broadwater mill—500 tons—also in Park City, backed by San Francisco capital, began work on tailings on the Homer ranch, which tailings it has under lease. Other new plants are the Utah Leasing Co.'s mill at Newhouse to retreat tailings from the Cactus mine, and the Caldo mill at Frisco to treat dumps from the Horn Silver. The flotation plants added to the mills of the Daly-Judge and Silver King Coalition are being rapidly completed. There has been an increase in milling capacity at the Daly-Judge of 50 tons a day; at the Silver King Coalition of 100 tons; and at the Utah Apex, an increase of 225 tons. The first mills mentioned are using the Callow flotation system, and at the Utah Apex the Janney system is in use. At the Apex mill there are 12 cells treating

150 tons of slimes a day. This plant is in the main mill building where the vanners used to stand, and has replaced the vanners. The concentrator of the United States Smelting Co., at Midvale, has been remodeled and enlarged from 350 to 600 tons daily capacity, and the capacity of the Huff electrostatic plant increased from 60 to 100 tons.

SEATTLE—Oct. 20

The Tolovana Paystreak has been definitely located on at least seven claims along the third tier bench of Livengood Creek counting every 20 acres as a claim. Counting No. 10, second tier, pay has been located on eight claims all told However, all of the prospectors working from 2 Above to 10 Above, on the third tier, are in pay dirt which goes from $1.25 to $1.50 to the square foot of bedrock. The paystreak is 150 ft. wide in places, although in others it is not more than 60 ft. Its width on all claims, however, yet remains to be determined. Several diamond drills have been brought into the district by the operators, to prospect their ground during the winter, when it is believed many new paystreaks will be uncovered. Portions of the Circle City, Fairbanks and Rampart districts have now been combined to form the Tolovana Recording District which has its own recording office.

Valdez Mines Are Busy taking out ore and from present indications this winter will be the most active in the history of the camp. As rapidly as possible the Cameron-Johnson mine is being made ready for reopening. The veins on these claims ran into a fault and were lost, necessitating the closing down of the property, but the hot weather of last summer shrunk the adjoining glacier to a depth of 100 ft. and exposed the reefs on the other side of the fault. The Granite mine is busier now than at any time since it was opened, and the mill is running steadily. The vein has been cut in a lower level, about 500 ft. below the present workings. An up-raise is being driven to drain the water from the upper levels and there is sufficient ore in sight to keep the plant running for several years. The Cliff mine which has been operating for some time has been closed down pending the adjudication of some suits filed against "Red" Ellis, the owner. The Ramsay-Rutherford, however, is sending bullion to Valdez every two weeks and the operators have plenty of high-grade ore blocked out. The Valdez Mining Co. is doing considerable development work and Jack Miller took out about $50,000 from the State Creek placer diggings this summer. The Midas copper mine owned by the Granby company is now in much better ore and is filling the bunkers preparatory to shipping. Mark Tatum, the discoverer of the Granite mine, has discovered a body of magnetite on Valdez Bay. The ledge, which is wide, has been traced on the surface for a distance of about 800 ft. and in many places gave assay returns of more than $35 to the ton.

HIBBING, MINN.—Oct. 23

Mesabi Going Dry Is a Probability. It is reported that the Indiana Bureau is about to enforce the Indian treaty of 1855, closing the 60 saloons in Hibbing and 20 in Chisholm. The report has received no official confirmation. All saloons on the Cuyuna Range have already been closed, as well as many towns on the Western Mesabi, including Coleraine and Bovey. Operators express great satisfaction at the change from wet to dry.

LUNING, NEV.—Oct. 21

Optimism in the Santa Fé Mining District, Nevada, is fostered by all the developments during the last few months. The Calavada Mining Co. completed the cutting of a station at the 1,000-ft. level during the past week and are now crosscutting to the ledge. This property is controlled by the Giroux interests and will, on installing a new cable, sink to water which they expect to strike at about 1,200 ft. Arrangements are completed for the financing of the Luning-Idaho Mining Co., and work will be started on a large scale early in November with the purpose of fully developing the orebodies which have been exposed in several places. This property lies in the belt containing the Fermina holdings now being extensively leased. The Calavada or Giroux property and the Duffy mines were recently purchased from J. N. Bealer and associates. The New York Cañon section is a regular shipper, over 40 tons daily going out from the many leasers working there. All of this ore is high-grade copper. It must run more than 6% copper to pay the hauling, freight and smelting charges. It illustrates the possibilities of this district, when one stops to figure the tonnage of low-grade copper that is left on these dumps for future treatment. The Nevada Gold Mines Co., Ltd., operating on an extensive plan, southwest of town, is in some exceptionally high-grade gold-silver ore and has made all arrangements for a steady production this fall. R. B Todd has arranged with eastern parties for the formation of a company to take over the Luning Gold Mines Co., and work will commence there in the near future. This property has been a good producer and has a large tonnage of milling ore blocked out. The development work at the Alameda Mines Co.'s ground is going steadily forward and with its large tonnage of low-grade copper it is rumored that a leaching plant will be installed at its camp in the near future. The fact that there are 20 sets of leasers working copper properties at a profit here, shipping in most instances copper around 5 to 10% speaks well for the camp. The starting of the leaching plant at the Nevada Douglas at Ludwig where this ore will eventually be shipped is expected to start a considerable development and mining boom here.

DOUGLAS, ARIZ.—Oct. 19

Cananea is Still Operating, although railroad communication is interrupted both from Nogales and Naco. The road from Nogales is reported to be in bad shape after General Calles' retreat and that from six weeks' to two months' work will be required to put it in operating condition. Recent arrivals state that nine bridges have been destroyed. Conditions are quiet in Cananea, the town being occupied by General Beltram with 150 Villistas, while to the south General Urbalejo is in authority with his band of Yaquis, who have been Villa adherents, but who may now take upon themselves "the supreme power" in all that part of Sonora which they can command. Naco and Nogales are in the hands of Carranzistas, so that together with the railroad service being out of commission, it may be necessary to stop operations at Cananea for lack of fuel, food and supplies. It is said that enough fuel and supplies are on hand to continue operations for two weeks, after which time a shutdown is inevitable, unless the railroad can be used and freight allowed to move southward before the expiration of that time. No disturbances have lately been reported from Cananea that in any way affected the operations of the company, it being reported that peace has been made between the company and the two contending factions, as far as the company's operations are concerned, by paying export duty to both.

[Cananea was forced to suspend operations Oct. 25, on account of the cutting of the railroad line by the Yaqui Indians.—Editor.]

Reports from El Tigre have, up to within the last few days, been optimistic, the management stating that operations would be continued regardless of the approach of Villa's men and that their arrival in camp was not looked forward to with apprehension; that it was expected that no hindrance of operations or molestation of Americans would ensue from the occupation of El Tigre by Villistas. However, within the last few days reports have been persistent that operations will be stopped and the Americans will attempt to reach the border as best they may. News of a fire at the mines of the Transvaal company's mine near Cumpas reached here yesterday, the building, supposed to have been the hospital, was burned to the ground, but the fire was not of incendiary origin.

La Colorado Mine, it is reported, was entered by gambucinos after it was closed down and stripped of all high-grade ore. The Minneapolis Copper Co. has stopped operations; most of the Americans employed have reached the border. Trains are not running south from Agua Prieta over the Nacozari railroad, but no breaking of the line has occurred to date. Autocars are run almost every day over the line as far down as Nacozari, enabling the Moctezuma Copper Co. to keep in touch with the few men who did not elect to leave at the general exodus last week.

TORONTO—Oct. 22

A Strike of More than 2,000 Employees of the various mines in the asbestos district, Thetford, Quebec, was inaugurated this week. The strikers demanded that wages be returned to the scale that was in force before the war. They also ask that they be allowed to purchase their supplies at any place they wish instead of the company's stores. At the outbreak of war the asbestos market was demoralized to such an extent that the companies were having a hard time, and the employees agreed to cut in wages. Since that time, however, the market has become active, and the strikers now ask that the old scale of wages be put in force.

VICTORIA, B. C.—Oct. 19

The Trail Smeltery has handled 347,348 tons of ore so far this year. Of this production 288,000 tons came from Rossland. Nelson shipped 2,425 tons. East Kootenay shipped 20,018 tons, principally from the Sullivan mine, while Slocan and Ainsworth districts furnished 14,843 tons. The shipments from mines in the State of Washington to Trail amount to over 16,000 tons so far this year.

The Mining News

ALASKA

YUKON GOLD (Dawson)—Is reported to have purchased holdings of John Holmgren in Ruby district and will put dredge on ground this winter.

CORDOVA MINING AND DEVELOPMENT CO. (Port Wells)—New mill being installed at mine near Golden in Port Wells district. Tunnels being driven.

MIAMI COPPER (Seward)—It is reported that A. H. Case, representing the above company, is investigating the Parker-Herschell properties near Seward.

ALASKA JUNEAU (Juneau)—It is reported that Charles E. Bruff, who built Sheep Creek Mill of Alaska Gastineau Co., will shortly come north to start work on new Alaska Juneau mill.

JUALIN ALASKA MINES (Juneau)—More men being taken to work at this property and indications are that mine will soon resume full operations left off at start of the European war.

VALPARAISO MINE (Ketchikan)—Is working mill at Dolimi to capacity and is considering construction of an addition. Tunnel is now in distance of 700 ft. and is being driven an additional 100 ft. into ore to keep plant busy all winter.

MATANUSKA COAL AND COKE CO. (Seward)—J. H. Sears, James McCox, and Roy D. Fonda have filed articles of incorporation for above company. Purpose of company will be to mine and sell coal from Matanuska field which will be tapped by Government railroad running in from Seward.

MOOSE PASS CLEANUP (Seward)—Ronan and James who few weeks ago bonded Moose Pass claims located during summer by Frank Skeen and J. W. Stevenson, recently ran 4½ tons of their quartz through an arrastre, recovering 80 oz. of gold from amalgam. Stamp mill will be erected on property next spring.

ARIZONA

Cochise County

BISBEE COPPER (Bisbee)—Organized to develop Winwood group of claims lying between Denn and Copper King, both proven ore areas and lying less than 1,800 ft. from Sacramento Hill. Campaign of churn drilling and other prospecting will be undertaken.

Gila County

INSPIRATION (Miami)—Mill is reported to be recovering 28 lb. of copper from ore assaying 1.7%, and is treating 5,000 tons per day. Both recovery and operations said to be fully up to expectations of company.

ARKANSAS

Newton County

ARKANSAS MINING DEVELOPMENT CO. (Little Rock)—Filed articles of incorporation, $100,000 capitalization, to operate in northern Arkansas zinc fields. Will begin operation at Spear mine in Newton County. Company has also leased properties in Marion County and will develop any other mineral deposits in state which can be profitably secured. Company will own no properties but will develop them on lease or royalty basis. John T. Fuller is president and general manager.

CALIFORNIA

Alameda County

RED MOUNTAIN (Livermore)—Third calcining kiln being installed at this magnesite mine. Brick for structure is being hauled from Pleasanton by three-wheel traction engine. Brick for kiln lining from Livermore Firebrick Co. was hauled by same engine. Traction engine will also be used in building new road to another magnesite deposit 2 mi. from the Red Mountain.

Amador County

PINE GROVE MINING CO. (Pine Grove)—Sold 125,000 shares at 25c. per share under permit of corporation commission and granted permission to sell an additional 100,000 shares at the same price.

SUTTER CREEK MINING CO. (Sacramento)—New incorporation with capital stock at $300,000, to operate East Eureka mine at Sutter Creek. Directors are Alexander Rennie, M. A. Nurse, J. R. Farrington, J. J. White, of Sacramento and Lee Shirars, of San Francisco.

PLYMOUTH CONSOLIDATED (Plymouth)—Preliminary statement of production and costs in month of September shows 10,800 tons of ore milled; total value $52,076; total working costs, $30,302; development cost, $411. Surplus over total costs, $22,363. Additional expenditures, $250. James F. Parks is superintendent.

Butte County

FORBESTOWN district is advancing both in development and prospecting. District lies chiefly in Butte County but extends into Yuba County. Development is progressing at Gold Bank, South Banner and Solano Wonder. Activity extends from Forbestown west to Morris Ravine about 3 mi. north of Oroville.

ORO ELECTRIC (Oroville)—Purchase of this corporation by Great Western Power Co. reported to include only public-service department. Dredging department will be continued as formerly.

VILORO (Oroville)—Gold dredge No. 2 destroyed by fire Oct. 19. Fire caused by electric short circuit in transformers. Dredge had been run 7 days since last cleanup and contained a large amount of gold on tables. After burning to water's edge, hull sunk. Total loss. Viloro Syndicate Ltd., owner.

Calaveras County

MOKELUMNE HILL district is being developed and prospected actively. Recent interest is due partly to sale by Frank J. Woodward to Harry Bridge of mines and claims known as La Fortuna, Colorado, Ben Hur and other properties including dam, water ditch and flume and rights of way.

Eldorado County

RAILROAD SURVEY from Diamond Springs to Ringgold section in progress. Purpose of road is hauling lime and lime rock from deposits on 380 acres owned by Mrs. E. J. Edick, Dr. W. W. Stone and National Surety Co. Property was formerly owned by W. J. Dingee and under bond to California-Portland Cement Co. Development depends upon construction of this spur track. Much of limestone is said to be well adapted to manufacture of cement.

SACRAMENTO VALLEY COPPER (Sacramento)—Deeds from Thomas G. Patton have been recorded, conveying title to mining claims and property in Greenwood district. These are: Copper Princess, Dundee No. 2, Shamrock No. 2, Brown Bear and 17 other claims.

Imperial County

OIL DISCOVERY reported west of Salton Sea by M. V. Dutcher, of Imperial. Oil was found seeping from slight anticline on floor of desert. Three hours digging produced about 20 gal. of heavy oil. Whether prospect is sufficient to encourage development is not stated. State Mining Bureau states that according to opinion of Dr. F. J. H. Merrill, Miocene beds in this region are not especially favorable to oil formation.

Nevada County

BRUNSWICK CONSOLIDATED (Grass Valley)—Expected that new 20-stamp mill, electrically driven, will go into commission within few days.

UNION HILL (Grass Valley)—John E. Pelton and associates reported to have acquired control and arrangements being made for extensive development. Shaft will be deepened to 1,000 ft. On 800 level orebody continues with development. The 20-stamp mill is crushing ore from this level. The cleanup Sept. 1 was $6,800; Sept. 15, $5,600, a total of $12,500 for 30 days' run. New directors recently elected John E. Pelton, Daniel E. Craig, E. W. Knowlton, of Pasadena, Otto B. Johnson, of San Francisco; G. S. Johnson, of Reno.

San Luis Obispo County

KLAU (San Luis Obispo)—This quicksilver mine reported producing 30 flasks a month. Mine has been idle for three or four years following destruction of furnace by storm and fire.

Siskiyou County

KANGAROO GULCH is proving to be one of richest quartz districts developed in County for several years. Joe Davidson and Sam Sargent have recently developed ledge about 4 ft. wide, carrying ore worth $3 to $5 per ton. Claim is an old one which has been developed for several years in small way.

Stanislaus County

DRILLING FOR OIL at Knights Ferry has been resumed after suspension resulting from breakage of machinery. Well is down 1,860 ft. and in as-reported that first oil sand has been passed. Probable that second oil sand will be reached within 2,000 ft.

Tulare County

PORTERVILLE MAGNESITE CO., (Porterville)—Two cars crude magnesite shipped in last week of September. Foundations for calcining kiln have been constructed and when plant is completed ore will be treated at mine. Survey made for spur track from Southern Pacific R.R., to base of magnesite hill.

RAWHIDE (Jamestown)—Reported that property has been sold to Silver Peak Mining Co., of Blair, Nev., and that company will move its surface plant from its mine in Nevada to Rawhide. John Mocine formerly secretary of California Metal Producers Association is engaged as superintendent. Stated that 3-compartment shaft will be immediately unwatered and retimbered where necessary. The shaft has an incline depth of 1,800 ft. This is one of producing mines owned and operated by Capt. Nevills and taken over by Patterson Estate of Fresno County following death of Nevills. Negotiation for sale of property was conducted by Alex Chalmers, manager of Lightner mine at Angels Camp, representing owners.

COLORADO

Clear Creek County

HOOSAC TUNNEL (Idaho Springs)—Company owning this property is being reorganized under permission from court in bankruptcy.

ONEIDA (Freeland)—Oneida-Stag mill is now equipped to treat ore by flotation, cyanidation having been discarded. Fifty tons of ore averaging $5.50 per ton are being concentrated daily at a ratio of about 12:1. Mine and mill employ 22 men.

GEORGETOWN TUNNEL (Georgetown)—Development will be resumed in this tunnel in Columbia Mt. within next 30

days. Georgetown Mining and Tunnel Co. contemplates early installation of electrically-driven equipment to advance tunnel several hundred feet.

SUN & MOON (Idaho Springs)—Development of this property has been undertaken by Von Tilborg Mining and Leasing Co. Particular attention will be paid to Garden vein east and west of Argo Tunnel on which drifting is in progress. A 2-ft. streak of payable ore has been opened carrying gold, silver, copper and lead. Nels Holme is superintendent.

COLORADO METAL MINING AND REDUCTION CO. (Georgetown)—Has been incorporated at $1,000,000, to take over properties of former concern organized to commercialize Malm dry-chlorination process. Proposes to revive operations in plant erected, several years ago, at Georgetown, and to reduce complex, low-grade ores of that region. Dr. Frank W. Traphagen, professor of metallurgy in Colorado School of Mines, is president of new company.

Gilpin County

PITTSBURG EXTENSION (Russell Gulch)—Fortune Mining and Milling Co. has been formed to operate this group of four claims adjacent to famous Pittsburg mine. New shafthouse contains electric hoist and air compressor. Development being pushed, with fine showing in Pittsburg vein.

Lake County

EVENING STAR (Leadville)—George E. Cramer is building new shafthouse at No. 5 shaft to replace one destroyed by fire a few weeks ago.

San Juan County

SILVER CROWN M. AND D. (Silverton)—New main tunnel, being advanced on Lee vein, has opened body of payable ore 8 ft. wide. About 3 ft. assays high in gold, silver and copper, balance of vein being milling ore. Experiments indicate that ore can be treated profitably by flotation process. James Burns is manager.

BALLARD (Telluride)—Leasers Anderson and Lacey have moved aërial tramway upper terminal from Ballard tunnel down to Butterfly crosscut which will hereafter be main mouth of mine. A block of ground above this adit, 300 ft. high and 600 ft. long, averages about $7.50 per ton. Mining and milling costs amount to $2.50 per ton.

Teller County

PORTLAND GOLD MINING (Victor)—Has acquired acreage along Wilson Creek, east of city of Victor, where it proposes to dispose of its tails from cyanide mill on top of Battle Mt. Sluice, more than mile long, is being constructed down slope of mountain.

IDAHO

Blaine County

WILBERT MINING (Arco)—Will pay initial dividend of $10,000 on Nov. 15. Stockholders have paid assessments of about $65,000. Mine, located in Dome mining district, is splendidly equipped with machinery, mill and railroad for transportation of ore from mine to mill. There are 16 patented claims, considerable reserve fund, and no debts. Ore is lead-silver and large tonnage has been blocked out.

Shoshone County

CŒUR D'ALENE GALENA (Kellogg)—This property is situated just above Caledonia, near Alhambra. Strike of 15 ft. of shipping ore is reported.

REX (Wallace)—Rex Consolidated Mining Co., controlled by New York people, is unwatering Rex mine preparatory to extensive development. Shaft down 700 ft. Probably require 30 days to unwater. Company has 250-ton mill, now rented to Tamarack & Custer.

OOM PAUL (Kellogg)—At meeting of directors held in Wallace Oct. 16 funds were provided and plans were made for continuing development work during winter. Enlarging of old Echo tunnel, through which Oom Paul is working, has been completed. To reach vein will require 3,000 ft. additional driving.

INTERSTATE-CALLAHAN (Wallace)—Aërial tramway connecting mill and railroad, 2 mi., is now in operation, eliminating wagon haul. Management estimates direct saving of $1 per ton. New boarding house to accommodate 70 men just completed and also 20 cottages for married employees. Ore blocked out for 4 years

HYPOTHEEK (Pine Creek)—Contract has been let by this company to Riblet Tramway Co. of Spokane for 3½-mile tram to connect mine with proposed mill. Hypotheek vein is anomalous in that carbonate ore persists to depth of 1,100 ft., although sulphides are beginning to predominate at that depth. New mill will be designed to treat 200 tons of carbonate ore daily and will be remodelled later to treat sulphide ore; it will be built near the tracks of O.-W. R.R. & N. Co. short distance below Enaville.

INDEPENDENCE-GETTYSBURG (Mullan)—Independence Lead Mines Co., of which Stewart Mining Co. is the controlling factor, has begun extensive development of its recently acquired property lying between Morning and Hunter. In tunnels Nos. 2 and 3, on Gettysburg claim, 10 and 12 ft. of ore of fair milling grade have been opened, and tunnel on Independence also shows ore. Compressor will be installed at once at No. 4 tunnel and work will be continued in all tunnels during winter.

RAY-JEFFERSON (Wallace)—At meeting of directors held at Wallace recently details of arrangements for 250-ton mill and winter development were perfected. Construction of mill will start as soon as weather permits and management hopes to have it finished by July 15, 1916. Crosscut extended southward from No. 2 tunnel in search of big Interstate-Callahan zinc vein has cut two small zinc-lead veins but has not yet reached its objective. No. 2 tunnel is on original Callahan vein and face is nearing boundary line. Raise will be driven from No. 2 to No. 1, distance of 432 ft., in preparation for stoping operations; this oreshoot is about 900 ft. long. Leasers on Carlisle claim, owned by Ray-Jefferson, have three cars of lead and zinc ore sacked for shipment. They are driving another tunnel to tap Carlisle vein 200 ft. deeper, at point where it is expected to intersect Ray-Jefferson vein.

MICHIGAN

Copper

MOHAWK (Mohawk)—This year is going to break all records for output and for reduction of costs. Plans calculated to bring better results in 1916 are going forward with speed. At shaft farthest north, first concrete skipway has been laid. No. 4 shaft has been sunk to 22d level. No. 5 is cutting plat at 17th.

TAMARACK (Calumet)—Old Osceola amygdaloid lode, as handled by crosscut in No. 2 Tamarack, now is furnishing considerable tonnage of rock. It is not, of course, anywhere near as rich rock as Calumet conglomerate upon which Tamarack originally built its faith and hope, but it is better than average of Osceola lode.

AHMEEK (Ahmeek)—Is to resume sinking in No. 3 shaft soon. Sinking at No. 4 will start few months later. Ahmeek's costs, including construction, will be close to 8c. per lb. this year if present status is maintained. Copper return is 24 lb.; slight falling off from average of 1911 and 1912 when it ran above 25 lb., but better than 1914 when it was 23.

ISLE ROYALE (Houghton)—Ran into real problem in sinking through sand to get to bedrock at No. 7. Second of three shafts now is going down. This is necessary, to put permanent hoisting shaft in angle of lode. There has been decided betterment in lode-rock contents lately. Last month it ran better than 14 lb. refined.

COPPER RANGE CONS. (Painesdale)—In connection with improved milling methods, cheaper and better extraction and utilization of horsepower at Lake Superior mills, turbine plant at Baltic stamp mill has been in successful operation for period of over two years. At Champion mill at Freda turbine plant now is being installed. It is practically a duplicate of the one at Baltic. Power poles are being set up between mines and mills so that surplus of this power can be used. Construction work now is so well along that it can be called into service within a few months. Success of sand filling system underground long ago proven. More economical handling of sand has been brought about.

Iron

ATHENS (Negaunee)—Shaft now down about 900 ft. Cage hoist is soon to be discontinued and skip hoist installed. Both will be used when mine is operatng.

SALISBURY (Ishpeming)—Mining operations resumed this week. About 75 men employed for present. Drift has been run 2,600 ft. south from shaft. Raising is now in progress to tap new body of ore.

MINNESOTA

Duluth

MINNESOTA STEEL CO. (Duluth)—First coke was made in ovens on Oct. 20. Blast furnaces have been lined and will be started as soon as two necessary pieces of machinery arrive from East. First steel billets will be turned out on Nov. 10 if present plans do not miscarry. There are now 100,000 tons of coal and 120,000 tons of limestone in stock at plant. More is arriving daily. Merchant mill and other mills will not be ready for operation until next spring. However, there is a great demand for billets and they will be shipped East.

Cuyuna Range

CUYUNA-SULTANA (Ironton)—Soo Line trackage to property will be completed early in November. At company's concentrator it is claimed average of combined iron and manganese in product is 55% or over.

CRAFT (Crosby)—A 1/8 interest in original lease of 12c. per ton on this property was recently sold for $30,000, placing valuation of $540,000 on whole lease. Holders of this lease have re-leased to N. P. interests at 62c. per ton.

Mesabi Range

STEPHENSON (Hibbing)—Shovels started loading ore this week. First work done this year.

CROSBY (Nashwauk)—Washing plant, nearing completion, differs from others on the range in that each unit of machinery has its individual motor, avoiding necessity for shafting and belts.

TIOGA (Chisholm)—Sinking was started this week. Temporary frame buildings being erected. Work will be rushed, hoping to start mining in 1916. All machinery will be electrically operated.

MISSOURI—KANSAS

OLD VIRGINIA MINING CO. (Joplin, Mo.)—Formed with 100,000 shares $1 par value. J. F. Dexter principal owner. Has already secured several acres of valuable mining land which will be developed.

GOLDEN STANDARD (Galena, Kan.)—Lease near New Century ground will have new 200-ton mill. Will be one of most modern and best-equipped plants in district. Work on construction commenced; expect to have ready for operation within three months. This is fifth company to start mining on Wyandotte land.

ATHLETIC MINING AND SMELTING CO. (Duenweg, Mo.)—Will enlarge mill to 1,000 tons capacity per 24 hr. instead of 350 tons, formerly reported. Another compressor also to be installed and 300 hp. boilers. Will have also new slime plant, 21 James tables, 2 Dorr thickeners, Dorr classifier, and other improvements.

BRADLEY L. AND Z. CO. (Joplin, Mo.)—Found rich run of blende on lease near Chitwood. Has been driving blank drift toward drill hole which showed good run of ore; struck orebody first of week; expect to have it opened up within week or two so will be able to keep mill, recently repaired, going steadily. Two more tables being added and capacity increased to 250 tons per shift.

SUPERIOR IRON AND FURNACE CO. (Iron Mountain, Mo.)—Old Iron Mountain tract of 1,700 acres has been bought by this company which proposes to reopen property and erect small charcoal furnace. Three charcoal furnaces were operated on this property about 40 years, which cleaned up oak timber for over 20 miles in every direction; second growth of oak is now sufficiently large for cutting.

MONTANA

Deer Lodge County

WASHOE REDUCTION WORKS (Anaconda)—Work was started Oct. 14 tearing out sixth section of concentrator preparatory to installing new system including flotation. Work is also progressing on building for additional flotation plant that will take care of slimes that cannot be handled in concentrator. New roaster building is going up rapidly. Sixteen of 28 furnaces, each 25 ft. in diameter are in place. One of them will be lined with cement instead of brick as an experiment. Furnaces are combination of McDougall and Wedge types, being water cooled instead of air cooled as is Wedge. Experimental zinc plant is operating satisfactorily and process promises to be great factor in development and exploitation of zinc resources in Montana. Experiments being made with coal-dust firing in furnaces of new leaching plant and if anticipations are realized system will be installed there.

Fergus County

BARNES-KING DEVELOPMENT (Kendall)—Has purchased all property of Kendall Gold Mining Co. in Fergus County for $100,000; $40,000 cash and remainder at $10,000 per month. Acquisition settles ore controversy existing between two companies.

Silver Bow County

BUTTE & SUPERIOR (Butte)—In September mine treated in its oil flotation plant, 37,278 tons of ore at cost of $3.19 per ton, recovering 8,968 tons of concentrate, valued at $81.50 per ton.

NORTH BUTTE (Butte)—Under new compensation law in effect in Montana, accident of Oct. 19 will cost North Butte company between $75,000 and $85,000 in pensions to be paid to relatives of dead men and to injured men themselves.

ELM ORLU (Butte)—Announcement made that contract will be let for new hoist and other improvements, to approximate total expenditure of $125,000. Hoist will be similar to that at Granite Mountain shaft of North Butte. Will have capacity for depth of 4,000 ft.

TUOLUMNE (Butte)—Output to be increased from 100 to 150 tons per day. Principal operations now being carried on on 2,000-ft. level. Orebody on 2,500-ft. level is 4 ft. in width; average copper content 4.6% with about 1 oz. of silver for every per cent. of copper. Among recent improvements are trams to convey lumber and fuel from railroad tracks to workings. Has 100 men on payroll. Ore being shipped averages 4% copper with considerable silver and small amount of gold.

EAST BUTTE (Butte)—The 800-ton flotation plant is practically ready for operation. Process is similar to that employed at Butte & Superior. Plant will treat all second-class ore and tailings from old processes which carry 14 to 16 lb. of copper to the ton. By flotation, loss in tailings will be reduced to about 4 lb. per ton. East Butte is mining about 900 tons of ore per day, of which 300 tons are first and 600 tons are second class. In addition to this it is handling Butte-Alex Scott ore.

NEVADA

Esmeralda County

SILVER PICK CONSOLIDATED (Goldfield)—Station completed on 600 level and east crosscut started to intersect vein encountered on 700-ft. level. Continuing north drift on 500 level on Phelan Vein.

JUMBO EXTENSION (Goldfield)—Dividend No. 5 of 10c. share declared by recent directors' meeting, payable Dec. 31, will leave surplus of $200,000 in treasury. Estimated production for September, 2,900 tons; gross value, $102,000. Net profit, $52,000.

SPEARHEAD (Goldfield)—After about eight years' inactivity, excepting leases, work is to be resumed on company account. Shaft to be continued from present depth of 250 ft. to 950-ft. point to cut latite-shale contact. Expect to intersect Wheeler ledge at 550 ft.

GOLDFIELD MERGER MINES CO. (Goldfield)—From latite shale contact drift, which was run at a vertical depth of about 1,200 ft., northeast crosscut has been started to intersect downward extension of Jumbo Extension orebody.

DIAMONDFIELD BLACK BUTTE REORGANIZED MINING (Goldfield)—Operations at main shaft temporarily suspended. Company will participate in Marine Lease on company ground which is extracting ore. Compressor and drills will be installed.

Nye County

TONOPAH ORE PRODUCTION for week ended Oct. 16 amounted to 9,761 tons, estimated at $201,658, compared with 9,583 tons last week. Producers were: Tonopah Belmont, 2,899 tons; Tonopah Mining, 2,800; Tonopah Extension, 1,850; West End, 672; Jim Butler, 1,100, and miscellaneous leasers, 440 tons.

TONOPAH BELMONT (Tonopah)—Net profit for September was $65,018 from 12,008 dry tons milled.

TONOPAH MINING (Tonopah)—Net profit for September was $51,720 from 12,057 dry tons milled; average value, $12.04 per ton.

JIM BUTLER (Tonopah)—Net profit for September, $22,232. Falling off from August, due largely to greater tonnage of low-grade ore from development.

WHITE CAPS (Manhattan)—Delinquent stock sale held in Tonopah, Oct. 16. There were 136,000 shares sold at price ranging from cost of assessment, 1½c. per share, to over 5c. per share. Practically all the stock was purchased by local investors who appear to have considerable faith in future of company. Developments in connection with future operation of White Caps, especially in connection with installation of adequate milling plant, are expected in near future.

Storey County

SIERRA NEVADA (Virginia)—On 2,500 level west crosscut at 35-ft. point exposed quartz in bottom of face assaying $11 per ton.

BELCHER-CROWN POINT (Gold Hill)—Saved 37 cars of mill rock from stopes in 1,300 Belcher raise. Jacket mill received 1,077 tons of dump rock and shipped one bar of bullion.

MEXICAN (Virginia)—Southwest drift from No. 3 on 2,500 level at 38-ft. point shows 3 to 4 ft. of low-grade quartz. No work done on 2,700 level owing to trouble at C. & C. shaft. Mill crushed 300 tons of ore, averaging $13.09 per ton.

CON. VIRGINIA AND OPHIR (Virginia)—Joint west crosscut from winze on 2,700 level reached 16-ft. point; face in porphyry. On Ophir 2,500 level, winze deepened to 15-ft. point. Saved 8 cars of ore averaging $7.80 per ton. Central tunnel north crosscut extended 5 ft. Saved 315 cars from stopes and development; milled 220 tons.

UNION CON. (Virginia)—Saved 83 cars of ore from north lateral drift stope on 2,500 level; assayed $49 per ton; last 35 cars averaged $63 per ton. In No. 1 raise, north drift advanced 4 ft. with face in ore averaging $50 per ton. East crosscut also started in hanging-wall side advanced 4 ft. with face assaying $30 per ton; 12 ft. across top at north end assays $50 per ton. Center and south end is in good milling ore.

NORTH CAROLINA

Stanly County

SOUTHERN ALUMINIUM CO. (Whitney)—Plans are under way for resumption of work on plant, about three-fourths completed, which was suspended at outbreak of European War. French interests known as L'Aluminium Francaise are in control of property in which is associated American Metal Co. Probable cost of plant on completion will be nearly $10,000,000.

UTAH

Beaver County

MOSCOW (Milford)—Deposit of zinc ore, much of it high grade, recently discovered on 200 level of old workings, is 10 to 15 ft. in width, and there are 150 ft. of backs. There is said to be about $100,000 worth of ore, and shipments are expected at rate of one car daily. New electric hoist is being installed on 600 level at Cullen shaft which will be sunk to 1,100.

Juab County

TINTIC ORE PRODUCTION for week ended Oct. 16 amounted to 124 carloads, estimated at 6,200 tons, valued at $155,000, compared with 137 carloads week previous.

Salt Lake County

ALBION MINING (Alta)—Lessees operating in old workings have made strike of good ore, and will continue work throughout winter. Eighteen men are working. Development is being done through Quincy tunnel of South Hecla.

Summit County

PARK CITY ORE PRODUCTION for week ended Oct. 16 amounted to 1,614 tons, valued at $64,000, compared with 1,498 tons week previous.

DALY-JUDGE (Park City)—Raise 200 ft. from 1,200 level has opened high-grade ore, which, it is expected, will make along contact, and develop into deposit such as found in other parts of property. Construction work on addition to mill, which is to contain Callow flotation plant has been completed, and machinery is being installed.

SILVER KING COALITION (Park City)—Shipments are being made at rate of 550 to 750 tons of ore and concentrates weekly, ore coming from 1,450 level and above. Some unusually rich ore is being mined. Eight cars, recently shipped, are reported to have assayed 84 oz. silver, 25% lead, with considerable zinc.

Tooele County

BULLION COALITION (Stockton)—Work is being continued on station at 200-ft. level below Honerine tunnel, where pumps are to be installed. All of ore produced by this property is taken out through this tunnel, which also supplies water for irrigation.

CANADA

British Columbia

BRITISH COLUMBIA COPPER (Greenwood)—September profits reported $10,000. Only one of three furnaces at smeltery in operation. This averaged 800 tons of ore per day. Development work on newly acquired Copper Mountain property continues, but production has not started.

Ontario

CONIAGAS (Cobalt)—This company has passed the dividend due Nov. 1 reason assigned being that company has limited its output on account of low price of silver.

CROWN-RESERVE (Cobalt)—This company has taken charge of Globe Consolidated mine in Trinity County, Calif. It agrees to spend $50,000 at rate of $4,000 per month to be repaid out of gross ore receipts. After all debts are liquidated Globe Consolidated will give Crown-Reserve a 55% control on 30-year lease.

MEXICO

Sonora

GREENE CANANEA (Cananea)—Closed down Oct. 25 as result of destruction, by Yaquis, of several bridges on line between Cananea and Naco, on American border, Cananea's port of entry. It is understood that no violence has been done to property, and officials of company do not expect any. Shutdown is made necessary to conserve supplies of oil at plant in order to keep pumps and other necessary machinery running.

SOUTH AMERICA

Peru

CERRO DE PASCO MINING CO. (Lima)—Will be reorganized through formation of new company with 1,000,000 shares, without par value. New company will issue $10,000,000 convertible 6%, 10-year bonds which will be bought by J. P. Morgan & Co. Of capital stock, 333,333 shares will be reserved for converting bonds after two years and up to 10 years at $30.

The Market Report

Metal Markets

NEW YORK—Oct. 27

All of the principal metals were stronger during the last week and a good business was done in each case.

The average prices for the metals in October will be reported on Nov. 3, Wednesday.

Copper, Tin, Lead and Zinc

Copper—A good business was done both with domestic and foreign buyers. By Saturday the market had advanced so that 18c., regular terms, was realized. Some of the larger producers who had previously stood aloof in the domestic market, nominally asking 18¼c., regular terms, met buyers and made sales at 18c. The Lake producers were reported as having made excellent sales at 18c. At the close the market stood at 17.90@18c., regular terms (17.70@17.80, cash, New York), most of the producers asking 18c., but being willing to make small concessions for desirable orders.

Copper Sheets are quoted about 23c. per lb. for hot rolled and 24c. for cold rolled, with usual extras. Wire prices are unsettled; quotations may be put at 18½@19c. per lb. at mill.

Copper Imports in the United States, week ended Oct. 9, are reported by the Department at 4,208,016 lb. metal and 426,799 lb. in ore and matte; total, 4,634,815 lb. Chief imports were from Peru, Chile and Canada. The exports for the week were 4,335,622 lb. copper; of which 2,543,102 lb. went to England and 1,412,234 lb. to Italy.

Tin—This market was steady, a fair business being reported done.

Lead—On Oct. 21 the A. S. & R. Co. advanced its price to 4.75c., and since then the market in New York has been steady at that figure. This advance was foreshadowed by the narrowness of the margin between the New York and St. Louis prices. Following the advance, the margin has continued narrow. Certain favorite brands of Missouri lead that are especially sought for the manufacture of sheet lead for sulphuric-acid chambers are temporarily unavailable, the producers being completely sold out for a month or six weeks ahead. All of the principal producers report a good business in lead being done during the last week.

Spelter—A large business was done during our last week of record, the total of sales being without any doubt in excess of 12,000 tons. Business was done chiefly with foreign buyers, especially for export to France. In the main it was done in contracts for deliveries running far ahead. These varied from contracts covering the first quarter of 1916, to contracts beginning immediately and running through the first quarter of 1916, and even further. For example, there was one very large sale covering deliveries November-June. With respect to the prices realized, conditions were rather erratic. Spelter for prompt delivery sold as high as 14c. in the latter part of the week, while the market for November at the close was about 13½c., for December, about 13c., and for January, about 12½c. Large contracts covering different periods realized a great variety of prices. The average of a little upward of 7,000 tons reported to us as sales for the week was about 12 cents.

Domestic consumers were again conspicuous by their absence. Nor was there any demand worth mentioning for spelter for early delivery. On the other hand there was no pressure to sell it. There seems to be plenty available but those who have it prefer to sell it only in conjunction with metal for later delivery.

The market for high grade and high-grade intermediate spelter is developing into an interesting situation. The supply of this is increasing but some of the producers find it difficult to sell it for the prices they think due them and are holding back their supplies until buyers become more generous. In the meanwhile the producers of these grades of spelter are increasing in number.

High-grade spelter is being offered by a new company, the American Spelter Corporation, 61 Broadway, New York. This company, in which George E. Nicholson is interested, has built a smelting plant at Kusa, Okla., near the new plant of Mr. Nicholson. The supposition is that it will refine by redistillation some of the common spelter produced by Mr. Nicholson.

The American Zinc, Lead and Smelting Co. is now producing high-grade intermediate spelter almost to the exclusion of common spelter.

The Owen Spelter Co. is building a 640-retort plant at Caney, Kan. Expected to be in operation in December.

Some of the recent demand for spelter for prompt delivery has been from new smelters who expected to be making spelter at this time, but have been delayed and have had to buy in order to fill contracts for delivery that they had entered into.

The American Zinc, Lead and Smelting Co. has opened a New York office in the Equitable Building, 120 Broadway. Charles W. Baker, a director of the company, is in charge.

Zinc Sheets—Business has been active, sales good but with no material change in quotations. The base price for carload lots is $16 per 100 lb. f.o.b. Pern, Ill., less 8% discount.

DAILY PRICES OF METALS IN NEW YORK

Oct	Sterling Exchange	Silver, Cts. per Oz.	Copper: Electrolytic, Cts. per Lb.	Tin: Spot, Cts. per Lb.	Lead: New York, Cts. per Lb.	Lead: St. Louis, Cts. per Lb.	Zinc: St. Louis, Cts. per Lb.

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St. Louis is given as the basing point. St. Louis and New York are normally quoted 0.17c. apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash. The difference between the price delivered and the New York cash equivalent is at present about 0.20c. on domestic business. The price of electrolytic cathodes is 0.05 to 0.10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St. Louis being the basing market. We quote the New York price at 17c. per 100 lb. above the St. Louis price.

Silver quotations are in cents per troy ounce of fine silver.

Some current freight rates on metals per 100 lb. are: St. Louis-New York 17c.; St. Louis-Chicago, 6.3c.; St. Louis-Pittsburgh, 13 1c.

LONDON

Oct.	Silver	Copper: Standard Spot	Copper: Standard 3 Mos.	Copper: Electrolytic £ per Ton	Copper: Electrolytic Cts. per Lb.	Tin: Spot	Tin: 3 Mos.	Lead: £ per Ton	Lead: Cts. per Lb.	Zinc: £ per Ton	Zinc: Cts. per Lb.
21	23¾	72⅞	73¾	88	18.35	151¾	153½	24 5/16	5 07	63½	13.22
22	23 13/16	73½	73½	88	18.29	151¾	153	24 3/16	5 02	66½	13.84
23	23⅞	.	.	.	.	.	.	.	.	.	.

26	23 15/16	72⅛	72½	88	18.16	154¼	154¾	24 1/16	5 05	68½	14 14
27	24	72¼	72⅞	88	18.12	154½	154⅞	24¼	5.00	68½	14 14

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 3 per cent. discount. For convenience in comparison of London prices, in pounds sterling per 2240 lb., with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4.86 = £1 = 3.21c., £20 = 4.29c.; £30 = 6.13c.; £40 = 8.57c.; £60 = 12.85c. Variations, £1 = 0.21½c.

Other Metals

NEW YORK—Oct. 27

Aluminum—Market conditions remain about the same. Stocks of imported metal are low and the chief domestic producer has none to offer for early delivery. Quotations are 53@56c. per lb. for No. 1 ingots, New York.

The action of the stockholders of the Southern Aluminium Co. is referred to on another page.

Antimony—The market has been strong and active and prices have advanced sharply. Sales have been good on the rise, and the tendency at the close is upward. Chinese and other ordinary brands are quoted at 35@36c. per lb. Cookson's, in which there is little doing, is held at 45@46c. per lb., New York.

Nickel—Quotations for ordinary forms are nominally 45@50c. per lb., according to size and terms of order. A premium of 3c. per lb. is charged for electrolytic nickel.

Quicksilver—Stocks continue scarce and the market is strong and advancing. New York quotations are $95 per flask of 75 lb. for large lots and $95@97 for smaller orders. A considerable shipment from California is reported held up in the Panama Canal. San Francisco reports by telegraph a brisk, strong market, with quotations $90@93 per flask. London price has been advanced 10s. and is now £16 per flask; no discount reported from second hands.

Gold, Silver and Platinum

NEW YORK—Oct. 27

Gold and Silver Movement in the United States, nine months ended Sept. 30, as reported by the Department of Commerce:

	Gold		Silver	
	1914	1915	1914	1915
Exports	$157,656,778	$12,936,680	$38,480,444	$35,557,489
Imports	39,941,946	265,871,213	17,791,486	25,276,972
Excess	E. $117,714,832	I. $252,934,533	E. $20,688,958	E. $10,280,517

Exports of merchandise in 1915 are valued by the Department at $2,529,575,095; imports, $1,302,281,591; excess of exports, $1,227,293,504. Adding the gold and silver gives $984,639,488 as the net export balance.

Platinum—Conditions remain about the same and no additional supplies seem to be in sight. Prices are a little uncertain, and higher rates may be asked. For the present, however, they remain at $50@55 per oz. for refined platinum and $55@60 per oz. for hard metal.

Our Russian correspondent writes under date of Sept. 24 that speculative interest in the market has decreased, owing principally to the increased difficulties imposed by the government to the export of platinum. Prices have fallen, though they still fluctuate considerably. Current quotations at Ekaterinburg for crude metal, 83% platinum, are 10@10.30 rubles per zolotnik; at Petrograd 38,000@39,000 rubles per pood—equal to $38.16 and $37.73 per oz., averages.

Iridium—This metal continues in demand and at a high price. Nominally $80@85 per oz. is quoted, but all sales are the result of negotiation and it is impossible to fix prices definitely.

Silver—Price has been maintained in London chiefly by purchases for home coinage and continental inquiry. But while the London price has advanced, the New York price has not quite held its own, owing to the decline in the rates of foreign exchange.

Imports of silver into Great Britain, nine months ended Sept. 30, were £7,178,943; exports, £5,713,480; excess of imports, £1,465,463, which compares with an excess of exports of £117,085 last year.

Zinc and Lead Ore Markets

JOPLIN, MO.—Oct. 23

Blende, high price $87.50; base per ton of 60% zinc, premium ore, $85; medium grades, $83@78; lower grades, $75@70; calamine base per ton of 40% zinc, car lots, $35@60; average selling price, all grades of zinc, $81.04 per ton. Lead, high price $56; base per ton of 80% metal content, $50@55; average all grades of lead, $50.87 per ton

SHIPMENTS, WEEK ENDED OCT. 23

	Blende	Calamine	Lead	Values
Totals this week	12,244,350	942,250	1,552,950	$564,910
Totals this year	469,530,190	35,168,430	73,035,260	20,700,840

Blende value, the week, $496,160; 43 weeks, $17,975,690.

Calamine value, the week, $29,270; 43 weeks, $812,340.

Lead value, the week, $39,480; 43 weeks, $1,912,860.

Lead prices, which sagged to around $50 base a week ago, closed tonight strong at $55. The blende market continued strong for premium ore; other grades weakened by midweek and found ready buyers at the week-end on the lower price level. The United States Smelting, Refining and Mining Co., which has been out of the market several weeks, was an active week-end buyer in the Miami camp at advanced prices.

Three weeks of excellent weather is creating a marked improvement in the production of blende and calamine, and the buying is strong enough to take up the production.

PLATTEVILLE, WIS.—Oct. 23

The base price paid this week for zinc ore was $75@72 per ton for 60% grades. The base price paid for 80% lead ore was $54 per ton.

SHIPMENTS, WEEK ENDED OCT. 23

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	4,584,180	406,300	530,920
Year	162,826,760	5,683,210	22,238,770

Shipped during week to separating plants, 4,669,460 lb. zinc ore

Iron Trade Review

NEW YORK—Oct. 27

The demand for finished steel continues strong and improving, domestic orders supplementing the export business. The mills are so full that deliveries are becoming uncertain.

Car orders, bridge orders and structural work are increasing rapidly, and contracts for material are now running well into and even over the first quarter of next year.

A buying movement in pig iron seems to have set in. Some large orders for basic pig have been placed or are on the market, and there are more inquiries for foundry iron. Recent advances in price are well held and more are in sight.

Exports from Baltimore for the past week included 380,885 lb. tinplates to London.

The stockholders of the Thomas Iron Co. have been notified that an offer has been made for their property and they will be asked to vote on giving an option.

The United States Steel Corporation in its preliminary report for the quarter ended Sept. 30 shows net earnings, after deducting operating expenses, ordinary repairs and renewals, as follows:

	1914	1915
July	$7,475,973	$12,048,218
August	7,584,926	12,869,099
September	7,215,083	13,793,327
Quarter	$22,276,002	$38,710,644
Depreciation and subsidiary charges		$8,864,853
Bond interest and sinking fund		5,703,631
Dividend on preferred stock		6,304,919
Total charges		$20,673,403
Surplus for the quarter		$18,037,241

For the nine months ended Sept. 30 the total net earnings were $60,727,979 in 1914 and $79,118,908 in 1915, an increase of $18,390,929. The September quarter this year showed a gain of $10,760,589 over the June quarter. The surplus for the quarter was equal to 3.5% on the common stock, but no dividend on that stock was declared, and no appropriations for new work were made.

PITTSBURGH—Oct. 26

Yesterday the Carnegie Steel Co. advanced bars, plates and shapes $1 a ton to 1.50c., Pittsburgh, just 10 days after its previous advance, and making $3 a ton advance in these products in less than a month. The 1.50c. price seems to be minimum for all the mills, but none will sell freely and some are practically out of the market. It is estimated that with the utmost reserve in accepting additional orders the mills will end the year with fully six months of obligations on books. Sheets are advancing, for delivery at mill convenience, and the leading interest is on the verge of opening its books for first-quarter contracts, at prices well above those now ruling for delivery at mill convenience.

In all finished steel products the pressure to buy has been steadily increasing, partly because prices promise to advance still more sharply in future, and partly because consumptive requirements are increasing. The railroads are faced with a car shortage not merely during the crop moving period, but afterwards, and there is inquiry in the market that may result in the placing of 40,000 to 60,000 freight cars in the next few weeks. Rail orders to date total about 550,000 tons. Car-repair material is in great demand and premiums for prompt shipment have been paid on a large tonnage altogether. The requirements of various domestic consumers are increasing, while the war demand continues very heavy and the demand from neutral countries shows further expansion. Since the mills have already been producing all the steel of which they are capable, and yet have been falling behind in

deliveries, the common prediction is that there will shortly be a veritable famine in steel.

Finished steel prices are now as high as they were at the top of the great movement of 1912, and are still advancing, more rapidly indeed than earlier in this movement. For a few finished-steel products premiums are offered for early delivery, but there is not much demand of this sort thus far, as buyers are well covered by contracts, as a rule. Since contracts are now being made in very conservative fashion by the mills there will probably be much more premium business going on in the market a few months hence. The small mills generally avoid contracts and will have steel to sell when the large mills are filled up tight for deliveries severa months ahead.

Pig Iron—All the furnaces that were quoting $14.50, Valley, on No. 2 foundry and malleable have withdrawn that quotation and are adhering to $15, the price that has ruled for weeks for next year's deliveries. Sales of about 10,000 tons of foundry and malleable have been made in this district in the past week. Bessemer and basic are strong, but without much activity. Predictions are more freely made that the pig-iron market will experience a sharp advance soon, as there are very few idle merchant furnaces, and the furnaces in blast have been reducing their stock piles, while prospects are that foundries will have larger requirements in future. We quote: Bessemer, $16; basic, malleable and foundry, $15; gray forge, $14.50, f.o.b. Valley furnaces, 95c. higher delivered Pittsburgh.

Ferromanganese—The Jones & Laughlin Steel Co. has leased Josephine furnace at Kittanning, Penn., a merchant furnace stack rated at 300 tons of pig iron a day, and now idle, the intention being to transfer the manufacture of ferromanganese from one of the Aliquippa furnaces, giving the steel company so much more basic pig-iron capacity. The manufacture of ferromanganese from imported ores was started by the Jones & Laughlin Steel Co. last December. Contract deliveries by English producers have improved materially and further improvement is expected, so that buyers have less hesitancy in making fresh contracts at the $100 price quoted for some time. Domestic producers still adhere to their former quotation of $115 on contract. Odd lots for early shipment generally bring from $105 to $110.

Steel—A contract has been made for 4,500 tons of open-hearth sheet bars for delivery over the first six months of next year at a price equivalent to slightly more than $28, Pittsburgh mill, and it is reported that bessemer sheet bars have brought about $27, Pittsburgh, for first quarter. Very little is being done for such deliveries, while for early delivery there are no sellers, mills stating that the market is nominally $25 for bessemer and $26 for openhearth billets, with $1 advance for sheet bars. Rods are $32@33, Pittsburgh. There is considerable contract business for first half to be closed in the near future.

FERRO-ALLOYS

Ferromanganese is still quoted at $100 Baltimore for imported; $110@115 for domestic, early delivery.—**Ferrosilicon** is higher; bessemer 10% is quoted $21.50 at furnace for spot, $21.50 for first quarter and $22 for second quarter. Higher grades run up to $31 at furnace for 15% alloy.—**Ferrotitanium** is $@12.5c. per lb., according to size of order and delivery.—**Ferrovanadium** $2@2.25 per lb. of contained vanadium.

IRON ORE

Shipments of Lake Superior ore are still heavy, and preparations are being made for a large demand through the winter.

Imports at Baltimore for the past week included 15,400 tons manganese ore from Brazil.

British Imports of Iron Ore nine months ended Sept. 30 were 4,527,970 long tons in 1914, and 4,700,016 in 1915; an increase of 172,076 tons.

Imports of manganese ore for the nine months were 406,765 long tons in 1914, and 209,814 in 1915; a decrease of 196,951 tons.

Exports of Manganese Ore from India for the four months of the fiscal year Apr. 1-July 31 were 245,086 tons in 1914, and 78,072 in 1915; decrease, 167,014 tons.

OTHER ORES

Molybdenite, 90% MoS_2, is quoted in London at 120s.—$28.80—per unit. The Australian government takes all the ore produced in that country at 105s. per unit—**Tungsten Ore** remains high, London quotations for wolframite, 65% WO_3, being 55s.—$13.20—per unit.

NEW CALEDONIA EXPORTS

Exports of nickel ore from New Caledonia, eight months ended July 31, were 39,216 metric tons. Exports of chrome ore were 28,828 tons. In July 14,189 tons chrome ore were shipped to New York. Exports of nickel matte were 1,709 tons.

COKE

Coke production of the Connellsville region for the past week is reported by the "Courier" at 421,091 short tons; shipments, 422,645 tons. Shipments of Greensburg and Upper Connellsville districts, 40,100 tons.

Coal and Coke Tonnage Pennsylvania R.R. lines east of Pittsburgh and Erie nine months ended Sept. 30, short tons:

	1914	1915	Changes
Anthracite	8,020,105	7,603,051	D 417,054
Bituminous	33,854,642	31,678,900	D 2,185,742
Coke	7,561,858	8,378,576	I 816,718
Totals	49,446,605	47,660,527	D. 1,786,078

The total decrease was 3.6%. Coke alone shows an increase this year.

British Fuel Exports nine months ended Sept. 30, in long tons:

	1914	1915	Changes
Coal	48,116,349	33,414,212	D. 14,702,137
Coke	824,325	684,689	D. 139,636
Briquettes	1,434,938	960,636	D. 474,302
Steamer coal	14,581,962	10,722,894	D. 3,859,068
Total	64,954,574	45,782,431	D 19,172,143

The steamer coal is the fuel furnished to steamships engaged in foreign trade.

SAULT STE. MARIE CANALS

Total freight passing through the Sault Canals in September was 10,974,557 short tons carried in 3,141 vessels. For the season to Oct. 1 the total freight was: East bound, 37,739,738; west bound, 10,643,865; total, 48,383,603 short tons. The number of vessel passages was 14,907, giving an average cargo of 3,246 tons. In all 12,139 vessels carrying 44,888,436 tons passed through the American locks; and 2,768, with 3,495,167 tons through the Canadian canals. The mineral freights included in the totals were, in short tons except salt, which is in barrels:

	1914	1915	Changes
Anthracite	1,589,501	1,448,734	D. 140,767
Bituminous coal	9,714,223	8,106,063	D. 1,608,160
Iron ore	25,923,002	33,761,762	I. 7,838,760
Pig and m'f'd iron	191,361	141,051	D. 50,310
Copper	47,237	95,373	I. 48,136
Salt, bbl	565,736	481,170	D. 84,566

Iron ore was 69.8% and coal 19.7% of the total freight reported this year.

Chemicals

NEW YORK—Oct. 27

The general markets show an improved tone and more active business. The supposed discovery of a plot in New York to destroy or damage several large chemical manufacturing plants has caused a good deal of talk in the trade. How much of the reports have an actual base is still uncertain.

Arsenic—Little or no change is reported. Business is quiet. Quotations are $3.50 per 100 lb. for large lots and up to $4 per 100 lb. for smaller parcels.

Barytes—Exports from Baltimore for the past week included 61,920 lb. barytes to Manchester, England.

Copper Sulphate—Business continues fair and prices are steady, with no material change. Current quotations are $6.50 per 100 lb. for carload lots, and $6.75 per 100 lb. for smaller parcels.

Nitrate of Soda—The market shows little change. Quotations remain about 2.45c. per lb. for both spot and futures.

The official statement of production of nitrate in Chile for the two months July 1-Aug. 31 gives a total of 6,365,022 quintals—288,131 long tons; a decrease of 4,187,742 quintals, or 39.7%, from last year.

Sulphuric Acid—Acid of 66°Bé. realizes $50@60 per ton in the seaboard markets in large lots. For 60°Bé. $30@35 is paid. These prices permit acid to be brought eastward from points so far west as Argentine, Kan., whence the freight rate is $11 per ton and still leave the producers a phenomenal profit.

PETROLEUM

Exports of mineral oils from the United States in August were 232,224,014 gal. For the eight months ended Aug. 31, the total exports were 1,493,937,331 gal. in 1914, and 1,518,884,770 gal. in 1915; an increase of 24,947,439 gal., or 1.7%, this year.

The Silver Hill Underground Hoisting Station

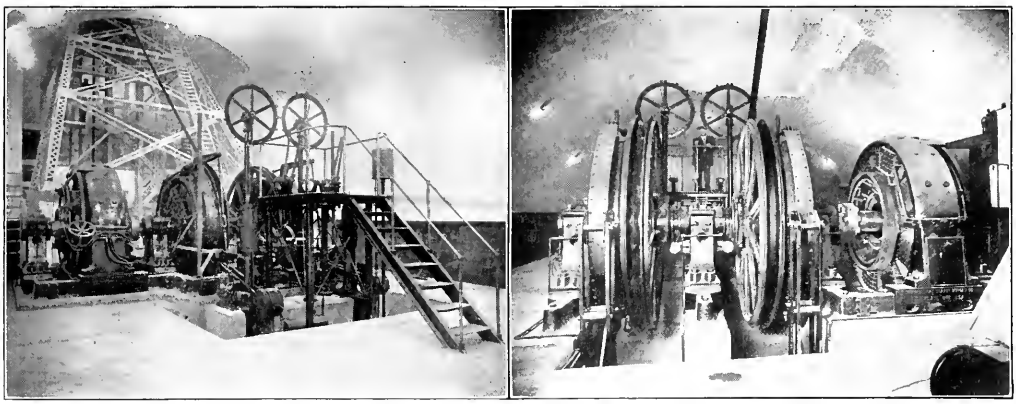
By James Humes*

SYNOPSIS—Unusually large underground shaft station cut in swelling ground traversed by a fault. Reinforced concrete used. Station is equipped with air compressors, blacksmith and carpenter shops, large hoist, all electrically driven, and a steel headframe. Total cost equipped, $104,070.

The largest underground hoisting station known to me is on the property of the Silver King Coalition Mines Co., of Park City, Utah, and is situated about in the center of the southwestern half of its holdings.

The western edge of the city limit is just about the eastern ore limit of this district, so far as known at the present time, and the King Coalition is mining 100 tons of ore per day within 1,400 ft. of the city limits and 300 ft. higher than the main street. This ore has to be hauled back into the mountain for about a mile, to the main hoisting plant, the haulage being accomplished by a 15-hp. electric locomotive, which delivers the trains of loaded ore cars at the 900-ft. level of the shaft. There is very little development work below the 900 level, east of the shaft. At this shaft, on the surface, are the shops, sampler and mill, hence all ore is brought to this point. Here also is the upper terminal of the aërial tramway that carries all crude ore and concentrates to the tracks of the Denver & Rio Grande and Union Pacific railroads. This shaft is 1,300 ft. deep and the lowest level is the mine's best producer; in fact, it is from the 1,300-ft. level that most of the shipping ore comes. The general course of this level is westerly, and the innermost workings are within 2,500 ft. of the Silver Hill shaft. This level measured along the main haulage way is about 1½ mi., and the length of the orebodies will measure fully half this distance. There are stopes working close up to the face of the main drift, and some of the ore is as high-grade as any that has been mined in the past and there is one-third of the company's undeveloped territory ahead of this level, in nearly the center of which is the Silver Hill shaft.

The Silver Hill shaft is at the inside end of the Alliance tunnel, which is 9,100 ft. long and is connected with the main Silver King shaft at the 500-ft. level by a 2,200-ft. crosscut. Both the crosscut and tunnel are laid with 30-lb. rails which make a speedy track for haulage purposes. It is intended to take all waste out to the portal of the tunnel and the ore to the Silver King shaft. The Silver Hill station is 1,650 ft. vertically below the surface.



ELECTRIC HOIST IN SILVER HILL UNDERGROUND STATION

From this description it will be seen: That the orebodies on the 1,300-ft. level as far southwest as is known show just as strong and as high-grade as any heretofore mined; that this level is getting so far ahead of the ventilating channels that it makes the ventilating problem

*Superintendent, Silver King Coalition Mines Co., Park City, Utah.

a serious one; that more than one-third of the undeveloped ground of this company lies southwest of these workings; that a large tonnage of ore will be mined above the 1,300 level and toward the new shaft, that could not be handled through the 1,300 level except at great cost. These are the main reasons for the Silver Hill shaft and the big station. The original plans evolved for a compressor and hoist room were carried out.

The plans called for a steel headframe, height to center of sheave, 38.5 ft.; sheaves 6 ft. diameter. Afterward this headframe was raised 8 ft. on concrete pedestals, making the height to center of sheave 46.5 ft. This change was a great improvement and was necessary to accommodate the skips, and it also placed the horizontal members of the headframe well up out of the way for handling long material into the shaft.

It so happened that a fault cut through the excavation, about in line with the dividing wall between the engine and compressor rooms; this added greatly to the cost of excavating and concreting these rooms.

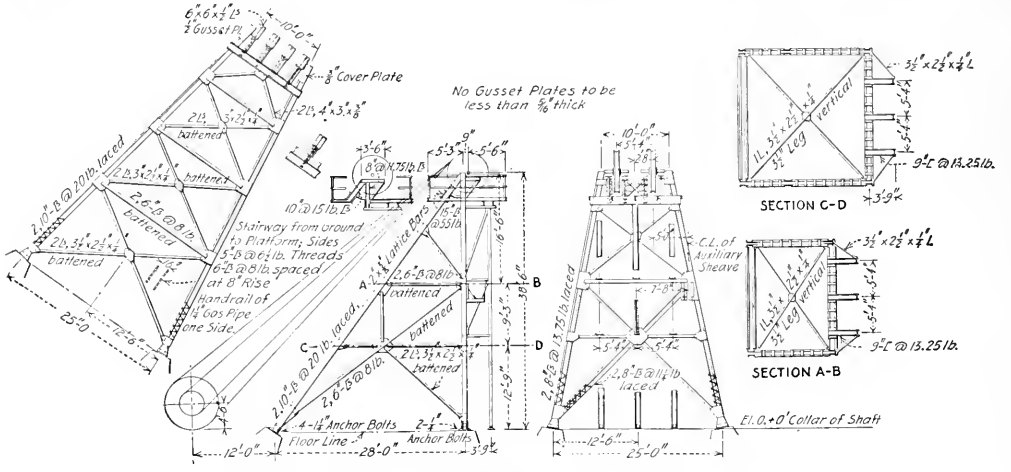
The width of the rooms being determined, work was started mining out a slice of rock the full width of the rooms and about 9 ft. high. While this undercut was being made, timber bulkheads and stulls were used to hold the back; this timber was of inferior grade, and most of it had been used in the mine before, so that it was not used for some purpose afterward. In the engine and compressor rooms were two floors of this kind of timbering and numerous stulls.

Very little powder had to be used after the undercut was taken out; indeed, the greatest concern was to prevent too much of the back from coming down. Two-inch plank was used for the wall forms, and 2x4's placed on edge over the arches.

The wall foundations were carried down below the floor level, and before placing the concrete a considerable number of holes were drilled with jackhamers, and in these holes were placed old car axles to give a bond. As the straight walls went up plenty of old rails were used for reinforcing.

A 1 to 3 mixture was used, with all the coarse rock it would cement—about 5 parts; this coarse rock was kept away from the face of the concrete about 1 in. In concreting the arches crushed rock was used which was put through the mixer with the cement. The sand was obtained from the mill, being taken from the Garfield roughing tables when the mill was running on carbonate ores. The cement used was made by the Portland Cement Co. of Utah, the works being in Parleys Cañon, near Salt Lake City.

This room is 44x25 ft. in the clear; the walls are 14 ft. to the spring of the arch and vary in thickness from 2



UNDERGROUND STEEL HEADFRAME, SILVER KING COALITION MINES

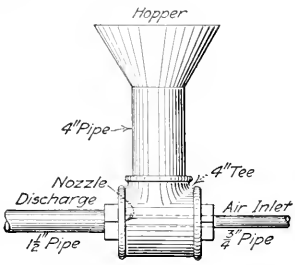
necessary to protect it from the blasts. When this undercut was taken out working lines and points were established from the shaft, which was at this time about 275 ft. in depth. From these established points sills were laid down that were to carry the false work, or timbers. These sills were level with the top of the wall plates of the shaft timber and parallel with same. All lines, angles and heights were afterward taken from these sills, hence the importance of getting them right in the beginning.

On these sills were erected square sets of the very best 10x10 Oregon fir; the caps and girts were cut the exact length of shaft posts and the posts are the right length to make end plates for the shaft, so that all of this timber will be used in the shaft. In fact, in all of this work the lumber that was used was so planned that it could be to 5 ft. The arch is elliptical, the major axis horizontal, and is supported in the center by two 18-in. I-beams, 48 ft. long. These I-beams had to be cut in two to get them into place and for transportation through the tunnel. They are supported in the center by a 12-in. extra-heavy pipe filled with cement, with a 24-in. hydraulic flange on each end. Resting on these beams and conforming to the curve of the arch are 80-lb. rails. These overlap on the beams and are spaced 3-ft. centers; the construction has the appearance of the backbone and ribs of a mastodon. Wherever the rock in the roof looked sound enough, long holes were drilled with stoping machines and an eye-bolt split at the end for a wedge was driven up into the bottom of the hole with a specially made hammer inserted in the chuck of the drill. Through the eye

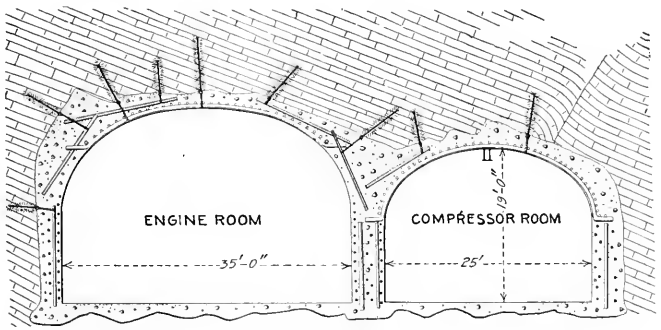
of these bolts and about the curved rails was bent steel cable; the ends were fastened together with the usual cable clamps. These loops were used wherever possible.

Discarded 4-in. boiler flues were placed on top of the curved rails, letting them lap at the ends. Thus they were 4 in. apart, except where they lapped, but before placing these tubes a network of small wire cable—discarded lacing from flat ropes—was woven from rail to rail in zigzag fashion. This network of wire was started at the spring of the arch and as it was brought up toward the center, the boiler tubes were placed in position. When a section was fixed in this manner, a coffer-dam was rigged at the open end and the pouring of the cement commenced.

The concreting of this room was a difficult matter, as the timber was set so close to hold the back that it was not easy for the men to handle the material and tools. When a man had no longer room to work above the reinforcing material, the space was filled with rock about as large as a man's hand. When the aperture was just about as full as could be of that-sized rock, a pipe was put through the forms, up through the loose rock and within ¼ in. of the rock in place; a second pipe was placed in the same manner, except that this one was pushed up against the solid back and then withdrawn ½ in. This last was the discharge pipe for the cement; the other was the discharge for the compressed air that carried up the cement which was forced up into the cavity with an air pressure of between 40 and 60 lb. This was continued just as long as any cement would be taken up. When the air would not take up any more, it was allowed to stand for 24 hr., when it was given another "shot." This was repeated several times. The concrete distributor is shown in the illustration.



CONCRETE DISTRIBUTOR



SECTION THROUGH SILVER HILL UNDERGROUND STATION

Method of Building the Engine Room

The engine room is 50x35 ft. The 35-ft. span has no other support than that given to it by the reinforcing steel. The curve of the roof, like the compressor room, is elliptical. The spring of the arch starts at the floor level and rises toward the shaft at an angle of 16° and then 37° until the ascending arch terminates with a height of 50 ft. Below the spring of the arch curved rails were placed on end and about 2 ft. apart; they extend above the spring of the arch from 7 to 8 ft. and were placed close to the face of the concrete. Long holes were drilled into the rock walls, in which were placed 1-in. eye-bolts to which the rails were tied by ⅞-in. wire ropes; some of the rails had as many as three such supports. The idea of reinforcing in this manner was to take all the strain possible off the main steel arches, or girders. These curved-steel girders were made of 4x4x½-in. angles bolted in pairs and placed 2-ft. centers. These also were supported by eye-bolts and wire ropes and laced with single strands taken out of the old tramway cables.

While the cement work of the hoist-engine room was in progress, work was carried on cutting out and timbering the space for the steel headframe. The timbers for this section had to be so spaced that the crossbeams would clear the headframe members. The first section, or floor as the miners called it, had 20-ft. posts, all timber being the best 12x12 Oregon fir. No sooner had this first floor been placed than men had to be put at work easing the rock from behind the posts on account of swelling ground, and from that time on a crew of miners had to be kept at that work. This did not look very promising for a permanent job.

When all the rock was out and the space ready for the headframe, the concreting of the engine room had been finished and all the forms were out, showing a clear space 35x50 ft., which looked so well that orders were immediately given to concrete the space required for the headframe and chutes. In doing this last, forms were put outside of the 12x12 timbers. The vertical walls of this section were well reinforced with 60-lb. rails laid horizontally; the back was arched the same as the other two sections, except the radius of the curve was less.

Several months have passed since these walls were concreted, but at no time have they shown the least evidence of the effect of the swelling ground, and there is no sign whatever of weakness in any part of the chamber. The difference between concreting and the best-known methods of mine timbering, in this instance, is the difference between success and failure. Had timber been used, there would have been no end to the cost of upkeep; as it is, the upkeep will be *nil*. Had this station been timbered, it would always have been damp, dark and cold; as it is, the temperature is just right, the walls are perfectly dry, the floors are cemented and all on the same level, the walls are whitewashed, so are the chutes and headframe, and the whole is well lighted with electric lamps; there are no dark corners and it is easy to keep it clean.

Along the tunnel and up to the shaft chutes for a distance of 160 ft., there are three tracks, and beyond the chutes there is enough track to accommodate 20 cars, which is about the size of the trains pulled by the three-ton motors. These tracks are fitted with automatic

switches so that the motorman does not have to get off the motor when he changes from the front to the rear end of the train. The chutes hold about 75 tons and are fitted with the Brunton arc chute doors. In front of the chutes there is considerable space that has been taken advantage of, by making it into a repair shop for drills and cars, equipped with a drill press, emery wheel, work bench, pipe-cutting tools and vises. Along the double tracks just mentioned are a blacksmith shop, carpenter shop and a change room for the miners, this last connected with the compressor room from which the warm air passes.

The blacksmith shop, about 100 ft. from the shaft, is cemented throughout. It was not the intention to do heavy blacksmith work in this shop, but for tools it is just the thing. It is equipped with a Leyner drill sharpener and a Case oil-burning forge, using a Utah 34 gravity oil, costing 8c. per gal. in small lots.

Compressor-Room Equipment

The installation in the compressor room consists of two Sullivan air compressors of the two-stage angle type: One 18x11x14 machine rated at 147 hp., capacity 704 cu.ft. per min., at 8,000 ft. belt driven by a synchronous motor-generator set; the other a 20x11x14 machine, capacity 873 cu.ft. per min. to 100 lb., at 8,000 ft., is direct-connected to a synchronous motor, type T. R. E. 32 poles, 225 r.p.m., 2,200 volts. These two compressors are to furnish air to run the shaft pumps and drills while sinking is going on. The sinking pumps will only be required to throw water from the bottom of the shaft to cement tanks that will be constructed every 200 ft. in the shaft. At each tank will be stationed a Jeanesville two-stage 600-gal. pump working against a head of 250 ft. At the 600 level will be placed a four-stage 750-gal. pump capable of working against a head of 600 ft.

In addition, in the compressor room, there is the belted exciter rated at 7.5 kw., 125 volts, for the larger compressor which has the usual amortisseur winding for starting. The switchboard for this machine is very simple, consisting of a single panel. The motor-driven exciter set is also in this room, and it is equipped with a standard type of starting compensator with automatic overload and low voltage protection, and is also equipped with a TD regulator for automatically maintaining constant voltage.

Engine-Room Equipment

The hoisting engine is a double-reel first-motion electric hoist built by the Wellman-Seaver-Morgan Co. The control is fine, the cages can be moved, in case of necessity, much slower than with a steam engine. The motor is 400 hp., and has ample power in reserve. The brakes and clutches are fitted with air cylinders which get their supply from a small 5-hp., G. E. direct-connected motor-driven two-cylinder 1,200 r.p.m. compressor.

The cables for the hoist are the flat-rope type, ½x4½ in., 1,600 ft. long. On the end of each rope is a 52-cu.ft. capacity skip, designed by me and built at our own shops. As these skips are too large for quick loading in the bottom of the shaft, provision was made for hanging a large bucket under them. These buckets are dumped into the chute pockets that are constructed for the different levels, and the ore hoisted at any time to the pockets at the shaft collar. The skips are provided with valves in the bottom, so that water can be bailed when necessary, and this has enabled the saving of the pumps more than once.

In front of the main hoist is a 10x12 double-cylinder single-drum hoist for handling the pumps, etc.

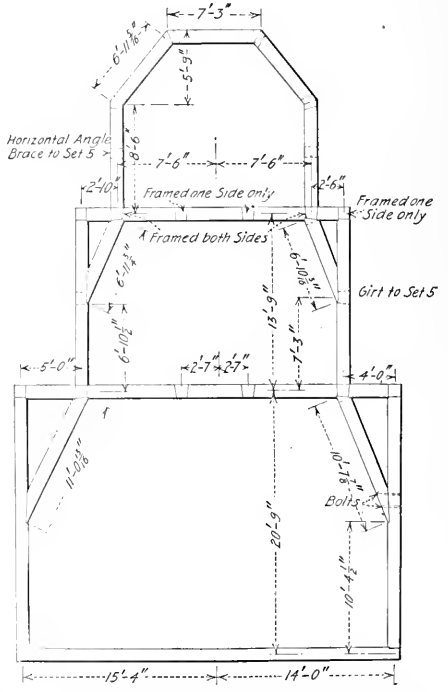
The Electrical Equipment

The electrical equipment for the control of the hoist consists of the following:

One direct-current generator driven at constant speed by the synchronous motor. Field windings consist of a regular commutating pole winding and three sets of windings on the main poles. The three sets of windings comprise a reverse series field of four turns per pole; a separately excited field giving a maximum of 5,000 ampere-turns at 125 volts; and a shunt field giving a maximum of 5,500 ampere-turns at 600 volts.

One direct-current motor direct-connected to the drum shaft of the hoist. Field windings consist of a regular commutating pole series winding, and a separately excited field on the main poles.

One drum-type controller and rheostat for controlling and reversing the separately excited field winding of the



TIMBER FRAMING FOR SILVER HILL UNDERGROUND HOISTING STATION

direct-current generator and by this means controlling and reversing the generator voltage, and hence controlling and reversing the speed of the hoist motor.

One rheostat (B) in series with the separately excited field of the direct-current generator for the purpose of making permanent adjustments of the control.

One rheostat (C) connected in series with the 600-volt shunt field winding of the direct-current generator for the purpose of making permanent adjustments in the control.

One hand-operated cutout switch for cutting out the 600-volt shunt field winding of the direct-current generator when it is required to operate the hoist at reduced speed (for repairs, examinations, etc.).

Two safety-limit switches for the purpose of automatically stopping the hoist at the top and bottom of the shaft.

One ammeter with zero at the center of the scale, for indicating the current to the hoist-motor armature and thus indicating the torque of the motor.

One voltmeter with zero at the center of the scale, for indicating the voltage across the hoist-motor armature and thus indicating the speed (and direction) of rotation of the hoist motor.

This control equipment is a modification of the standard Ward Leonard variable voltage control, the essential difference between the two being that in the standard system each notch of the controller corresponds to a certain definite speed (forward or reverse), whereas in the modified system each notch of the controller corresponds to a certain definite torque (forward or reverse).

In the operation of this system at starting, the controller can be moved instantly from zero to maximum position, resulting in maximum torque in the hoist motor. When it is required to stop the hoist, the controller may be brought back instantly to the zero position, corresponding to approximately zero torque.

The equipment is as fool-proof as a standard Ward Leonard control with mechanical limit on the controller, and by reason of the elimination of this mechanical retarding gear on the controller drum, the operation is easier and more flexible. In its characteristics it closely resembles the control of a steam or air hoist, with the advantage that the single controller handle performs all the operations corresponding to regulation of the throttle and the reversing valve gear of a steam or air hoist.

In order to provide for slow-speed operation of the hoist, a cutout switch is connected in the 600-volt field circuit, and when this is cut out the equipment operates in the same way as a standard Ward Leonard control, each notch of the controller representing a certain definite speed, except that the whole range of the controller covers speeds from zero up to about one-third speed.

The portion of the electrical equipment that is on the operating platform of the hoist consists of the controller which, as aforesaid, regulates the torque of the hoist motor; a large illuminated dial ammeter reading both ways, which indicates the amount and direction of the torque; a large illuminated dial voltmeter reading both ways, which indicates the direction and speed of rotation of the hoist; and a small cutout switch as described, for use when running at slow speeds, for stretching rope, examining shaft, etc. The total cost of the underground station is given in the accompanying table.

CONSTRUCTION AND EQUIPMENT COSTS

Excavations, including the engine and compressor foundations 144,900 cu.ft. at $0.09 (labor only)		$13,041 00
Framing and placing timber		3,150.00
Tramming 14,400 cars (18 cu.ft. capacity) by electric motors to portal of tunnel, 9,000 ft. at $0.0812 per car		1,169.28
Tramming 2,872 cars of sand from mill to station 10,000 ft. at $0.09. Cost per cu.yd. concrete	$0.15	258.48
Placing forms. Cost per cu.yd. concrete	.9572	1,650.00
Bending reinforcing steel	.1085	187.00
Power, concrete mixer, crusher, small hoist	.4266	735.00
Placing concrete and crushing rock	6.7656	11,657.19
Cement	3.9621	6,826.76
10% loss in timber and plank for forms, etc.	.2386	411.12
Reinforcing steel bought	.6828	1,176.59
	$13.2918	
Tunnel haulage, by electric motors, timber-machinery, reinforcing material, headframe, men and all other supplies		3,252.24
Transferring machinery from wagons to mine trucks, unloading same at station and placing the heaviest pieces in position and laying 9,000 ft. of electric cable		3,618.00
Railway and wagon freight		2,056.72
Lighting		293.17
Explosives		934.78
Timber for skip pockets, etc.		456.00
Iron and steel for skips, chute bottoms, bolts, etc.		585.82
Electrical consulting engineers		1,000.00
Shop labor, building skips, erecting machinery, installing electrical apparatus, headframe, etc.		4,291.32
		46,750.47
Electrical machines, compressors and hoist		57,320.00
Total cost of underground station built and equipped		$104,070.47

The portion of the electrical equipment that is on the operating platform of the hoist consists of the controller which, as aforesaid, regulates the torque of the hoist motor; a large illuminated dial ammeter reading both ways, which indicates the amount and direction of the torque; a large illuminated dial voltmeter reading both ways, which indicates the direction and speed of rotation of the hoist; and a small cutout switch as described, for use when running at slow speeds, for stretching rope, examining shaft, etc. The total cost of the underground station is given in the accompanying table.

I wish to express my thanks to Lenord Wilson, electrical engineer, and to J. B. Ambler, electrical expert for the General Electric Co., for their help in the preparation of the electrical data in this article. In the construction of the station Merrian Longmire, who was foreman in charge, should be commended. The work was done with credit to himself and profit to the company, and in all the dangerous work not a man was hurt.

*

Lead-Smelting Projects in the Coeur d'Alene

The following interesting article, slightly condensed, that appeared in the circular of Norman & Muxen, of Spokane, Sept. 20, 1915, shows how the smelting situation in the Cœur d'Alene is viewed by some eyes.

Since last month evidence has accumulated to support our analysis of the smelting situation as it affects the Cœur d'Alene district. There is now no doubt that the American Smelting and Refining Co. has so manipulated matters as to assure to itself practically undisputed sway in the district. Combination with its erstwhile rivals has killed competition, and when outside contracts expire, as they will within the next 18 months, the entire district will pass under the domination of the most unscrupulous and rapacious combination that has ever squeezed life out of legitimate business. As we see it, indications now point to a defensive and offensive alliance with American Metal Co., the last rival.

To understand the situation it is necessary to go back a little. Ohio & Colorado Smelting Co. is controlled by the American Metal Co. and the latter controls the product of the great Interstate-Callahan lead-zinc mine. Lead ores of Tamarack & Custer, controlled by the Day family, are also under contract to Ohio & Colorado, but, since Hercules closed down in May last, its ores have been forwarded to the East Helena plant of the "trust," under an amicable arrangement between the two smelting companies. Tamarack & Custer is now connected with the rehabilitation of the old Le Roi smelter, at Northport, Wash.

Some weeks ago it was rumored that the sharp drop in price of lead was due to a severe fight between the two big selling agencies, which had previously entered into a "gentlemen's agreement" to divide the European demand. However, it was not surprising when announcement was made that the "trust" had declined to divide up a big British order with the American Metal Co. Then price-slashing was commenced, and meanwhile the supposed rivals made more secure their hold upon the producer. Peace has doubtless settled down over the frenzied belligerents, and both are laughing in their sleeves at the easy conquests they have made.

A little later occurred the trouble between stockholders of Interstate-Callahan, and again is seen the light-fingered touch of the "trust" and its latest satellite. Eugene R. Day, president and general manager of Hercules, brother of Harry L. Day, president and general manager of Federal Mining and Smelting Co. (controlled by the "trust") and of Jerome J. Day, president and general manager of Tamarack & Custer Consolidated, has been named receiver by the Shoshone County courts while litigation affecting smelting contracts with American Metal Co. is in progress. It all makes a nice, compact little family party.

Harry L. Day, brother-in-law of Edward Boyce, former president of the Western Federation of Miners, multi-millionaire of Hercules making, still remains as manager of Federal. The alignment therefore seems to indicate a combination of American Metal-Guggenheim-Days against Bunker Hill & Sullivan. International Smelting Co., a subsidiary of Anaconda, which made such a drive after lead-smelting business three years ago, has lain down with the metallic lion like a

good little lamb. There is no possibility of real competition in that direction, nor from United States Smelting Co., and contracts now in effect will doubtless be dropped as they expire. This will throw Marsh and Hecla into the maw of the combination within two years.

Further, we believe that James Hill, the railroad magnate, has joined the combination with attractive freight rates and that the stage is set for a "ring-around-the-rosy" dance, with the lead production of the Cœur d'Alenes in the center and American Metal, Jim Hill, Daniel, Simon, Isaac and lesser Guggenheims, Harry L., Eugene R. and Jerome J. Day as the coryphees. It will be an all-star bill, but expensive entertainment for the Cœur d'Alene producer. Before the whirl is over we expect to see Tamarack & Custer taken in by the "trust" through Federal and an effort made to mulct the fool American public once more with this moth-eaten, disreputable and dry-squeezed stock.

The third paragraph of the foregoing strikes us as betraying imperfect information about the lead market, and there may be some misconceptions in other paragraphs, but the essay is entertaining, even if it be inaccurate.

Interstate-Callahan Fight

WALLACE CORRESPONDENCE

The fight for control of the Consolidated Interstate-Callahan company, which was precipitated at Duluth a few months ago and resulted in the election of two boards of directors, will now be transferred to the Federal court for the district of Idaho. When the Interstate and Callahan companies were consolidated several years ago, each received 170,000 shares in the new company. Those to the Interstate were distributed among the stockholders of the original company, but those to the Callahan have been held intact, the latter company still maintaining its corporate existence. Of this amount about 70,000 shares are owned by James F. Callahan, and his friends own enough to make more than a majority. Therefore they control the Callahan company. An effort was made in the district court here to force a distribution of this stock, but it failed, the court holding that it was a matter of which the directors had control. At the recent annual meeting in Duluth, what is known as the Callahan-Boutin faction attempted to vote this stock, which, with other shares friendly to them, would have given the control. The Robbers-Percival crowd, which is in actual possession of the affairs of the company, refused to permit the Callahan stock to be voted and proceeded to elect directors and officers. The Callahan-Boutin faction thereupon withdrew and also elected directors and officers.

The next move for control was made in this city a few weeks ago, when the Callahan Mining Co., Joseph Boutin and others filed complaint against the Consolidated Interstate-Callahan Mining Co., as represented by the officers elected by the Callahan-Boutin faction, and asked for the appointment of a receiver to take charge of the company's property and handle its business until such time as the question as to which set of officers was legally elected is settled by competent authority. Judge Woods, of the state court, granted the petition and appointed Eugene R. Day, manager of the Hercules mine, receiver. It was then, for the first time, that the Robbers-Percival faction, at the New York office, heard what was doing. The receiver had filed a bond of $300,000 and was about to take possession of the mine, when an appeal was made to Judge Woods to stop further proceedings until the Robbers-Percival crowd could be heard. This was granted, and a few days later a question of jurisdiction was raised and Judge Woods was asked to grant time for an appeal to the United States court for the district of Idaho. This was granted, and the appellants were also required to file a bond for $300,000 as a guarantee against damages on account of the receiver's not taking charge. The Consolidated Interstate-Callahan Mining Co. is an Arizona corporation and none of its officers are residents of Idaho. The case was submitted to Judge Deitrich, of the Federal court, who a few days ago rendered his decision granting the petition to transfer the case to the United States court. In his opinion Judge Deitrich admitted that the case involved many perplexities and that he would, if desired, hear further argument upon motion to remand, and this will doubtless be the next move of the Callahan-Boutin attorneys. The attorneys for the Robbers-Percival faction will no doubt move to have the entire proceedings dismissed and at the same time endeavor to bring the question of the Callahan stock to an issue in the Federal court, in the hope of securing an order for its distribution to the individual stockholders.

The case is one of absorbing interest here, and outside of the many interesting points involved that appear in the court record, the opinion is advanced in some quarters that the appointment of a receiver would eventually be followed by a readjustment of large interests, which might mean the obliteration of the Interstate-Callahan in the process of effecting a consolidation upon even a greater scale.

The Wisconsin Zinc District—III

In the article on the Wisconsin Zinc District—III, in the *Journal* of Sept. 4, 1915, p. 387, an error occurred

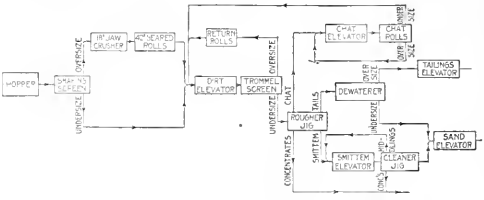


FIG. 32. FLOW SHEET OF ZINC TREATMENT

through which an entirely foreign illustration appeared as Fig. 32. The drawing shown herewith is the flow sheet which should have been shown.

Victoria Mineral Output, 1914

The mineral output of Victoria during 1914, according to the Secretary for Mines, was valued at £2,086,183, a decrease of £85,294 from the preceding year. The gold produced (113,218 oz.) was valued at £1,755,236. Other items, in descending order of value were: Coal, 617,536 long tons; antimony ore, 7,603; tin ore, 53; diatomaceous earth, 1,000; silver, 13,460 oz.; gypsum, 1,077 long tons; kaolin, 808; brown coal, 2,715; manganese ore, 20; magnesite, 23 long tons.

The Potential Waterpower of the Pacific Coast is given by J. W. Beckman at 11,504,000 hp. (San Francisco meeting, American Electrochemical Society). Of this Washington has 4,932,000 hp.; Oregon, 3,148,000 hp.; California, 3,424,000 hp. The amount developed is said to be: Washington, 306,000 hp.; Oregon, 105,000 hp.; California, 430,000 hp.

Geology of Tintic Ore Deposits*

SYNOPSIS—Early mining done about equally in igneous and limestone formations. Since 1913 all production has come from limestone in northern section of district. Monzonite, the youngest of the igneous rocks, considered the mineralizing source of all important Tintic orebodies. There are three types of ore deposits—limestone-igneous contact, limestone replacement, and igneous deposits.

The first geological report on the Tintic district to be issued was that by Tower and Smith, published in 1899, in the form of a paper in Part III of the *Nineteenth Annual Report of the United States Geological Survey*, and also as *Folio No. 65, Geologic Atlas of the United States*. About four years ago a second investigation was begun by Waldemar Lindgren and G. F. Loughlin, of the United States Geological Survey. With the exception of a paper on the oxidized zinc ores of the Tintic district by Mr. Loughlin, the results of their work are still unpublished.

Situation, Topography and History

The Tintic district lies about 65 mi. due south of Salt Lake City and on the west central slope of the Tintic Mountains, a short range which forms the connecting link between the Oquirrh Mountains on the north and the Cañon Range on the south—the group constituting the first of the Basin ranges to the west of the Wasatch Mountains.

The productive portion of the district embraces an area about 6 mi. long and 2 mi. wide, which is divided between Juab and Utah Counties. Within this area are the towns of Eureka, Mammoth, Robinson, Silver City and Knightsville.

As in most of the Basin ranges, topographic relief is strong, dropping rapidly from peaks of 8,100 ft. above sea level to elevations of 5,600 ft. in Tintic Valley on the west and 4,500 ft. in Goshen Valley on the east.

Tintic is among the oldest mining camps in Utah, being antedated only by Bingham, Rush Valley and Little Cottonwood. Ore was first discovered in the monzonite about 1 mi. east of Silver City in December, 1869, and the district was organized in the following spring. The first claim recorded was the Sunbeam, located Dec. 13, 1869, on the first discovery. This was followed in quick succession by locations in the limestone; first on the Mammoth ledge near the middle of the district, and shortly after on the Eureka Hill ledge near its northern end.

Mining operations began at once with the construction of two mills and as many smelteries during the first 12 months. Once located, the orebodies have been found to be fairly persistent.

During the early days of the district the production was about equally divided between the deposits in the igneous rocks at the south end of the district and those in the limestone at the north end. But upon the exhaustion of the oxidized ores in the igneous rocks, due to high water level, the balance of production was shifted to the deposits in the limestone; and since the closing of the Swansea mines at Silver City in 1913, the entire production has been from the latter deposits. The total production of the district to Jan. 1, 1914, was $143,398,119.

Areal Geology of the District

The rocks of the Tintic district consist of Paleozoic sediments and a variety of igneous rocks of Tertiary age.

The sedimentary rocks consist mainly of quartzite and limestone having a total thickness of 12,000 ft. or more. For economic and lithologic reasons they have been subdivided in descending section as follows:

Humbug sandstone Humbug limestone	Constituting the Humbug formation of the United States Geological Survey.
Tetro limestone Carbonaceous shale Blue Fossiliferous limestone Chief Consolidated limestone Gemini limestone White-lime-shale	Constituting the Godiva limestone of the United States Geological Survey
Centennial limestone Golden Ray limestone	Constituting the Eureka limestone of the United States Geological Survey.
Tintic slate Tintic quartzite	Constituting the Tintic or Robinson quartzite of the United States Geological Survey.

At the top of the section is the Humbug sandstone, on the east slope of the Godiva Mountain. This is 224 ft. thick, and is not known to be ore bearing.

The Humbug limestone, 378 ft. thick, consists mainly of nearly pure, coarse-grained gray limestone with a few intercalated beds of arenaceous limestone of yellowish buff color. This formation is well exposed on the upper east slope of Godiva Mountain and has carried most of the ore in the Godiva-Sioux Mountain and Iron Blossom ore zones.

The Tetro limestone, 355 ft. thick, consists with little variation of hard, fine-grained, blue cherty limestone which is not known to be ore bearing.

The Carbonaceous shale, 160 ft. thick, is essentially a thinly bedded, black shaly limestone, containing bands of black chert, and weathering to a platy or shelly surface. It is most unpromising as an ore-bearing medium and is nowhere known to be mineralized.

The Blue Fossiliferous limestone, 542 ft. thick, consists of 300 ft. of blue cherty limestone in beds from 1 to 3 ft. thick, resting upon 242 ft. of blue, highly fossiliferous limestone in thin beds separated by thin partings of impervious clay shale. This formation has been quite extensively prospected, and found to carry no orebodies of importance.

The Chief Consolidated limestone, 615 ft. thick, consists of a series of contrasted horizons which in descending order, have the following characteristics:

80 ft. of very coarse-grained, massive dolomitic limestone, on the whole quite favorable to mineralization.

64 ft. of fine-grained, siliceous, hard, brittle, black limestone, which is generally barren, though running the entire length of the ore-zone in the Chief Consolidated mine.

38 ft. of medium-grained, fairly pure, blue limestone in thin beds, but with a few black shaly partings, which appear to offer some resistance to mineralization.

31 ft. of coarse-grained, pure, white to light-gray limestone, which appears to be especially favorable to mineralization.

120 ft. blue, flaky and fairly pure limestone, which also appears to be especially favorable to mineralization.

72 ft. of coarse, mottled, light-gray, massive dolomitic limestone, readily susceptible to mineralization.

212 ft. of fine-grained, ashy-gray impure limestone with 11 or more intercalated thin beds of quartzitic sandstone

*Abstract of paper to be presented by Guy W. Crane, Eureka, Utah, at meeting of American Institute of Mining Engineers, February, 1916.

The horizon lies to the west of the ore zone proper, and its character is such as to discourage exploration for ore within its limits.

The Gemini limestone, 902 ft. thick, consists of 45 or more relatively thin alternating horizons of blue, gray, light-gray and white limestone of varying texture and hardness, but all generally distinctly bedded. The formation is especially characterized by its purity, that is, lack of siliceous members, and general susceptibility to mineralization.

The White-lime shale, 920 ft. thick, consists throughout of fine-grained, bluish-gray, thinly bedded shaly limestone with a few thin conglomeratic beds of the interformational type. It is generally extensively sheeted where folded and weathers to a yellowish white, whence its name. It is characteristically unfavorable to mineralization and is not known to be ore bearing.

The Centennial limestone, 798 ft. thick, consists of four relatively thick horizons of massive dark-blue limestone interspaced by as many relatively thin horizons of thinly bedded light-gray limestone and one 6-ft. member of thinly laminated light-green shale. Except for the shale and two 20-ft. impure sandy horizons, the entire formation is apparently favorable to mineralization.

The Golden Ray limestone, thickness 1,559 ft., consists of five thick horizons of heavily bedded dark-blue to bluish-gray dolomitic limestone interspaced by five relatively thin horizons of fine-grained light-gray to white, thinly laminated impure limestone. While this formation is not known to be ore bearing, a large part of it possesses characteristics that are apparently favorable to ore deposition in other ore-bearing horizons.

The Tintic slate, thickness 358 ft., consists essentially of thinly laminated green slate with intercalated bands of impure, gray banded limestone near the top and thin bands of brown quartzitic slate near the bottom. The formation is highly sheeted, due to folding. Its siliceous and wholly barren nature does not invite exploration.

The Tintic quartzite, the lowest member in the stratigraphic series, is not fully exposed, but has an estimated thickness of 5,000 to 7,000 ft. It is for the most part a pure, compact, fine-grained quartzite, white to pink in color. Bedding is indistinct and readily confused with a pronounced sheeting due to folding. Occasional interspaced thin beds of pebble-quartz-conglomerate break the general massive nature and lend a clue to the structure.

The Igneous Members

The igneous rocks consist of rhyolite, andesite, tuff and breccia, and monozite, all of Tertiary age.

The Packard rhyolite, locally referred to as porphyry, occurs as surface flows and intrusive dikes. It occupies a large area in the northern end of the district and, underlying the town of Eureka, extends to the north and east in a range of hills of which Packard's Peak is the most prominent. Its thickness at this point probably exceeds 1,000 ft. The rhyolite varies in color from pink and light purple to light and dark gray. In texture it ranges from glassy to highly granular, with flow banding as a common characteristic.

No metalliferous deposits are known to occur with the Packard rhyolite. Its chief economic interest lies in the numerous springs issuing from the lower slopes, from which the entire water-supply of Eureka and the mines in that section of the district is obtained.

Large areas of andesite with associated tuff and breccia lie to the east and south of the productive portion of the Tintic district. They are for the most part older than the metalliferous deposits and have no genetic relation to the latter.

The Sunbeam monzonite is confined to the southern half of the district, where it forms the country rock over an area 4 mi. in length, north and south, and 2 mi. wide. It is the youngest of the igneous rocks and occurs in the form of an intrusive stock, cutting and enveloping fragments of all the earlier formations. On the north it lies in an irregular but nearly vertical contact with the limestones, which it has metamorphosed through a zone varying from 300 to 500 ft. in width. On the east and south it is in irregular contact with the andesite. Its western boundary is obscured by the overlapping, alluvium-filled valleys, Ruby Hollow and Diamond Gulch, which show it to have been deeply eroded.

In color it is light to dark gray, usually with greenish-brown tinge. In texture it is normally evenly granular, but varies from porphyritic on its east and west boundaries to granitic where it is in vertical contact with the limestones.

What is known as the Swansea rhyolite is probably a rhyolitic phase of the monzonite and belongs to the same period of intrusion. The monzonite is a formation of first importance, since it has been the mineralizing source of all the important orebodies in the Tintic district.

Structure Mainly Synclinal

The sedimentary formations are folded into a simple and fairly symmetrical overturned syncline, the major axis of which strikes north and south and pitches slightly to the north. The axial plane of the fold dips about 60° to the west, resulting in vertical and often overturned dips in the beds of the east limb of the syncline, while the angles of the dip of the beds in the east limb are correspondingly low, rarely exceeding 40°. By reason of its pitch, the syncline becomes wider to the north where the trough is folded into a series of crenelations, forming a wide synclinorium. South of the Ajax fault, which extends from the Mammoth mine east to the Iron Blossom No. 3 mine, no synclinal structure is obtained. While the beds on the north of the fault are steeply inclined, conforming to the normal structure of the syncline, those on the south are relatively flat, lying with gentle dips to the east, in which direction no return dips are observable, because of a thick covering of volcanic rocks.

The folding of the sediments was accompanied by extensive faulting, fracturing, fissuring and sheeting. The major faults are of the transverse type, striking in a nearly east-west direction across the line of the major fold. These faults show lateral displacements ranging from 500 to 3,000 ft. The direction of throw is usually to the east on the south. Connecting the major faults at various angles are numerous minor faults showing displacements ranging up to 200 ft. Rotary faulting is common, as is shown by marked disparity in the attitude of the beds along the plane of the faults. The major faults are usually accompanied by one or more parallel faults, inclosing a breccia or sheared zone. The occasional occurrence of breccia zones and slickensides parallel to the bedding planes must be interpreted as evidence of some faulting of this type. None of the faults are known to extend into the igneous rocks, which are evidently of later

origin. While it is probable that most of the faulting occurred during the period of folding, it is not unlikely that some faulting and fracturing accompanied the intrusion of the monzonite, though none of this origin has been recognized.

Fractures and fissures occur in both the igneous and the sedimentary rocks. Sheeting is confined to the latter.

In the Sunbeam monzonite and its porphyritie phase, the Swansea rhyolite, are numerous ore-bearing fissures which have a general north-south direction, but vary from as much as N 20° W to N 45° E. These fissures are of the stretch type, due to shrinkage accompanying the consolidation of the igneous intrusives. For this reason they do not extend into the adjacent sedimentary rocks.

The sediments during the period of their deformation were extensively fractured and sheeted, generally along shearing planes. The fractures, which are usually steeply inclined, are most numerous in the steeply dipping beds and in the vicinity of the major faults. They trend at all angles, those in the northeast and southwest quadrants being the most abundant.

Sheeting has occurred in the quartzite, slate and more impure shaly limestone beds, where these have been closely folded. It is best developed in the Tintic slate, and the White-lime-shale, along the western limb of the syncline. The Tintic quartzite also is extensively sheeted.

The Ore Deposits Are of Three Types

There are three types of ore deposits in the Tintic district: limestone-igneous contact deposits; limestone replacement deposits; and deposits in igneous rocks.

At numerous points along the contact of the limestone and the igneous rocks, particularly the Packard rhyolite, are thin deposits of iron and manganese oxide associated with more or less red and greenish jasperoid and clay-iron stone. The jasperoid has been observed to grade into the limestone of which it is a replacement. The iron-manganese deposits occur both at the contact and filling cavities in the limestone near the contact.

Deposits of this type are widely distributed over the district, particularly its northern end, where because of the resemblance of the associated jasperoids to certain phases of the quartz in the productive limestone replacement deposits, they have received considerable attention from prospectors.

Locally, small quantities of silver and gold have been reported, but except for the iron ores that have been mined intermittently for fluxing purposes, these deposits have no economic importance.

The ore deposits in the igneous rocks are confined to the southern half of the district, where they occur as veins in well-defined stretch fissures in the Sunbeam monzonite and Swansea rhyolite. The veins are as a rule nearly vertical, with frequent croppings at the surface. They have general north-south courses but vary from N 20° W to N 45° E. One, the Sunbeam, has been worked through a length of 2,000 ft. on the strike, but most of them pinched out at a distance of a few hundred feet.

As shown by the old workings, the veins vary in width from a few inches to 10 ft., usually pinching with depth. The average width is about 2 ft. The ore in its unaltered state consisted of silver-lead sulphides and sulpharsenides, occurring in bands and lenses in a gangue of quartz and pyrite. These materials constituted about three-quarters of the mass of the vein. Considerable copper occurred in some of the southern mines, while those in the north have produced lead and silver almost exclusively. Gold occurred sparingly in but few of the deposits. Ground-water level was usually encountered at a depth of from 200 to 700 ft., depending upon the proximity of the sediments. Above water level, the ores assumed the usual oxidized character, with some secondary enrichment. Below ground-water level there was marked decrease in the value and size of the orebodies. This and water troubles usually caused an early cessation of mining, and today all these properties with one or two exceptions are indefinitely abandoned. Since the closing of the Swansea mines in 1913, there has been no noteworthy production from deposits of this type.

Four Ore-Bearing Zones

The orebodies formed by replacements in limestone are confined to the northern half of the district and include all the now productive mines. Mining operations have developed four nearly parallel ore-bearing zones, within which the orebodies appear to be virtually continuous, though at intervals the connections may be mere seams of quartz. These zones have a general north-south direction and may be defined as follows:

The Eureka zone, including the Centennial Eureka mine on the south and extending through the Eureka Hill, Bullion Beck and Gemini mines to the Ridge & Valley mine on the north.

The Mammoth zone, beginning at the Black Jack mine on the south and extending through the Lower Mammoth, Phenix, Gold Chain, Mammoth, Grand Central, Victoria, Eagle & Blue Bell mines to the Chief Consolidated mine on the north.

The Godiva-Sioux Mountain zone, beginning at the North Star mine on the south and extending through the Red Rose, Carisa, Northern Spy, Utah, Uncle Sam, Yankee, May Day and Apex mines to the Godiva mine on the north.

The Iron Blossom zone, beginning at the Dragon Consolidated mine on the south and extending through the Black Dragon, Governor, Iron Blossom Nos. 1 and 3, Sioux Consolidated, Colorado Nos. 1 and 2, and Beck Tunnel No. 1 mines to the Beck Tunnel No. 2 mine on the north.

The Eureka zone is the shortest and at its northern end is divided into two or more channels. At its southern end it appears to connect with the Mammoth zone through the Grand Central mine, in which case it is a branch of the Mammoth zone. These two zones lie on the west limb of the syncline, where the beds are nearly vertical and their orebodies have great vertical range.

The other zones are well defined throughout their length of about 2 mi. and apparently have no interconnections. They lie near the trough of the syncline, and their orebodies are correspondingly shallow.

Like replacement deposits in general, those of Tintic are very irregular in form, but in both shape and size they are governed within certain limits by the associated structures. This explains the dissimiliarity in occurrence of the orebodies in the different zones.

In the Eureka and Mammoth zones, which are in the nearly vertical beds of the west limb of the syncline, ore has been mined from the surface to the depth of 1,800 ft.; the orebodies as a rule conforming very closely to the bedding in both strike and dip.

If any one form of orebody can be said to be typical of these zones, it is that of an irregular sheet, pinching and swelling along the line of the beds and feathering upward into chimneys, or pipes.

Where the ore channel is crossed by faults or zones of fracture, there is usually an enlargement of the orebody along the line of intersection of the faulting and the bedding. This gives rise to another very common type of orebody, characteristic of the western zones, where it is usually the most largely productive form.

At the intersection of the ore channel by a fault, it is not an uncommon occurrence to find that the line of mineralization turns from the plane of the beds and follows the fault for distances up to 100 ft. or more, before again taking the usual course along the beds. Occurrences of this kind probably also account for the occasional division of a single ore channel into two or more parallel ore channels.

In the Godiva-Sioux Mountain zone, the known orebodies have smaller vertical extent but greater lateral variation than do those in either the Eureka or Mammoth zones. This is probably due to the fact that the Godiva-Sioux Mountain zone lies nearer the trough of the syncline where the beds dip at relatively lower angles, seldom exceeding 60° and sometimes as low as 15°.

In the Iron Blossom zone, particularly in its northern half, we find still greater restriction in both vertical and lateral extent of the ore than of the other ore zones. This, again, can be attributed to the controlling influence of the structure, since this portion of the zone takes a course directly in the trough of the syncline. The south half of the zone traverses beds dipping at angles up to 30°, and here the orebodies resemble more closely in form those of the Godiva-Sioux Mountain zone.

Among the several formations described, there are only four which are known to be ore bearing. These are the Centennial, Gemini, Chief Consolidated and Humbug limestones. In each case the ore-bearing formation contains several horizons of coarse, soft and relatively pure limestone, while the remaining formations are more generally fine-grained, hard and siliceous, in that they carry varying proportions of shale and sand.

The influence of magnesia in the limestone is not clearly shown. One dolomitic horizon in the Chief Consolidated formation is quite generally mineralized, while another is only sparingly so. The dolomites are usually coarse-grained—a favorable factor, which may offset the disadvantages of difference of solubility.

By reason of the folded and broken state of the limestone beds, the ground-water level is extremely low (about 4,765 ft. above sea level) in the sedimentary rocks. This puts it at depths beneath the surface of from 2,300 ft. in the higher properties to 1,500 ft. in those having shafts at relatively lower positions. This condition has led to more or less complete oxidation of the original sulphide ores, with some downward segregation of the ore minerals, and some enrichment due to shrinkage in volume.

Origin, Distribution and Character of the Ore

Very little ore has been mined below ground-water level; but developments have demonstrated its continuity into that zone, and something as to its original sulphide character. Above the water level the ore is largely oxidized.

From the earliest days an important variation in the north and south distribution of the ore minerals in the several ore zones has been noted. It appears that gold-copper ores predominate at the south end of the zones, gradually giving place to increasing proportions of silver-lead ores to the north, where the latter minerals predominate. As a result the mines in the vicinity of Mammoth have been chiefly producers of copper and gold, while those in the vicinity of Eureka are chiefly producers of silver and lead. Zinc is found associated with the ore of both ends of the district, probably more frequently in the mines at the north. Vertically the ore zones show no such striking variation in mineral content; but generally the good gold stopes are in the upper levels.

The vertical extent of an ore zone is governed primarily by the accompanying structures. The more nearly vertical are the inclosing beds, the greater the vertical range of the orebody. The presence of faults and fissures also favors greater vertical range, irrespective of the angle of the bedding. Their influence is greatest, of course, where the bedding is nearly vertical. The large orebody in the south end of the Chief Consolidated mine, which has a vertical range of 1,000 ft. or more, rakes along the inclined line of intersection of vertical beds and a large cross break.

Importance of the Monzonite

The occurrence of the Tintic deposits both within the monzonite and in the immediately adjacent limestones; the character of the mineralization, which is now generally considered to be due to the action of hot solutions; the progressive change in the mineral composition of the ore with increased distance from the monzonite—all point to this rock as the prime factor in the mineralization. In this respect the deposits of Tintic are like the many others in the southwestern part of the United States, and particularly in western Utah, which are as a rule closely connected in origin with igneous (commonly monzonite) intrusions.

The localization of the deposits within the monzonite was determined by the formation of stretch fissures within the congealing magma, which furnished channels of circulation for the hot solutions that were given off during the period of cooling.

The localization of the deposits in the limestone was controlled in part by the attitude and character of the beds and in part by the presence of fissures, some of which were probably produced during the period of monzonite intrusion.

Following the fissures caused by the intrusion, the hot mineral-bearing solutions found their way through the fractured and metamorphosed zone into the unaltered limestone, where they naturally took the easiest avenue afforded. This, in the absence of open faults and fissures, was the plane of the bedding.

Where the dip of the beds approached the vertical, the solutions found channels at various elevations, ascending or descending as conditions allowed, but laterally confined to relatively narrow limits. Flat-lying and low-pitching beds, on the other hand, have tended to confine the solutions to a more nearly horizontal course, at the same time permitting greater lateral shift.

At the intersection of faults, the solutions were allowed to spread out both vertically and laterally, producing orebodies of large size and great vertical range. The

process of mineralization has been primarily a replacement of the limestone with quartz and varying proportions of copper, lead, zinc, and silver sulphides, presumably due to decreasing temperature and pressure in the solutions as they run their northerly course.

Soft, coarse-grained, nearly pure limestones have been much more readily replaced by the solutions than the harder, fine grained, and more siliceous beds. Certain horizons of the latter type, even where directly in the course of the mineralized zone, are found to be uniformly barren.

Of the four zones so far developed, not one has been traced to a logically demonstrated terminus, and it is by no means established that similar and equally productive zones do not exist, still undiscovered, in the district.

Power to Condemn Land

By A. L. H. Street*

The right of a mining or ore-milling company to condemn land for use in its operations is recognized by the Nevada Supreme Court in the recent case of Goldfield Consolidated Milling and Transportation Co. vs. Old Sandstorm Annex Gold Mining Co., 150 Pacific Reporter, 313.

It is a well-settled principle of constitutional law that private property cannot be condemned for private use, but that, on payment of full compensation to the owner, it may be taken for "public" use. It is also well recognized by the courts that it is within the power of a legislature, acting in good faith, to determine what shall constitute "public" use. Acting under this authority, the Nevada legislature has declared that mining for valuable minerals is the paramount interest of the state, and therefore a public use. Applying this statute, the Supreme Court holds in the case above cited that the use of land as a place upon which to deposit tailings from an ore mill is a public use for which land may be condemned.

It is further decided in the same case that since it is a general rule that, when a corporation seeks to exercise the right of condemnation, its discretion in the selection of land will not be questioned by the courts if it acts in good faith and not capriciously, it is no defense to proceedings to condemn certain land that there are other tracts available for the purpose; and that an absolute necessity for taking the particular land is not necessary to authorize its condemnation.

Another point adjudicated is that the facts that the land sought to be taken in this case had been located and patented as mining ground, and that there was a possibility that it might be used in the future for mining purposes, no work having been done on it for several years, did not prevent condemnation, especially in view of the fact that the condemning company expressed willingness that the order of condemnation should provide that the owners of the ground might carry on mining operations so far as the same would not interfere with the company's operations, and especially since it is likely that the land will be freed from the tailings, for the deposit of which the land is to be used by the company, after being retreated.

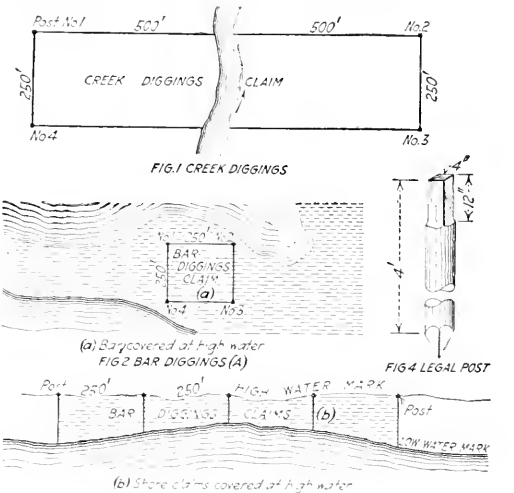
Seaweed Potash is reported to be under investigation in Monterey County, Calif., by the Hercules Powder Co. A launch is being used for gathering the seaweed or kelp, which will be shipped to San Francisco for experimenting.

*Attorney, St. Paul, Minn.

Acquiring Placer-Mining Claims in British Columbia

By J. A. Macdonald*

The rules and regulations for prospecting and laying out mining claims in British Columbia differ materially from those of the Yukon and the other provinces under federal jurisdiction. While under the Dominion regulation a miner or prospector may stake out a 500-ft. claim along a creek, in British Columbia only 250 ft. is permitted; while for "bar diggings" as well as "dry diggings," the area is limited to 250 ft. square, with important distinctions, of course. As in the other provinces, every person over 18 years of age, as well as every joint-stock company, is entitled to all the rights and privileges of a "free miner" and shall be considered a "free miner" upon taking out a free-miner's certificate, which is not transferable. This certificate, for which the



STAKING PLACER CLAIMS IN BRITISH COLUMBIA

fee is $5, runs from the date of issue to midnight on May 31 next after its date. The certificate is brief:

> This is to certify that.....of..... is entitled to all the rights and privileges of a free miner from midnight on the [date of issue] day of.....19.... until midnight on the thirty-first day of May, 19..
>
> Issued at..... on the.....day of.....19..
>
> [Signature of issuing officer.]

In case a person allows his free-miner's certificate to expire, he may, at any time within six months from the date of such expiration, obtain from the proper officer—the Gold Commissioner or the Recorder—upon payment of a fee of $15, a special-miner's certificate. Every free miner shall be entitled to locate and record only one claim on each separate creek, bar or dry diggings.

Placer-mining claims are divided into three classes, with a subclass: (1) Creek diggings, which claim shall be 250 ft. long, measured in the direction of the general course of the stream, and shall extend in width 1,000 ft., measured from the general course of the stream,

*Topographical Surveys Branch, Department of the Interior, Ottawa, Ontario.

500 ft. on either side of the center, see Fig. 1; (2) bar diggings, which shall be (a) a piece of land not exceeding 250 ft. square on any bar that is covered at high water, see Fig. 2, or (b) a strip of land 250 ft. long at high-water mark, extending in width from high-water mark to extreme low-water mark, see Fig. 3; (3) in dry diggings a claim shall be 250 ft. square, similar to bar diggings shown in Fig 2. On the discovery of a new locality, however, a free miner is entitled to a claim 600 ft. in length, or a party of two, 1,000 ft. Abandoned claims are treated as a new locality, on the discovery of a new stratum of earth containing precious metals.

"Placer mine" and "diggings" are synonymous terms and mean any natural stratum or bed of earth or gravel mined for gold or other precious metals. "Creek diggings," Fig. 1, means any mine in the bed of any stream or ravine; while "bar diggings" means any mine between high- and low-water marks on a sea, river, lake or other large body of water, as in Figs. 2 and 3. "Dry diggings" means any mine over which water never extends.

Locating and Recording Placer Claims

Every placer claim must be, as far as possible, rectangular in form and be marked at the corners by four "legal posts" firmly fixed in the ground. One of these is called the "initial post," and on this is written or attached this notice:

> Take notice that [set out name of each locator] have this day located this ground as a placer claim (or as a set of placer claims), to be known as the "..... Placer Claim" ..... feet in length. Its general direction is .....
> Dated this.....day of.....19...

On one post mark "Initial Post" and fix the notice on that post. On the notice is written: (a) The name of the locator; (b) the number of his free-miner's certificate, the date of the location and the name given to the claim.

In timbered localities all boundary lines of a placer claim must be blazed so that the posts can be distinctly seen, and the locator shall also erect "legal posts," not more than 135 ft. apart on all boundary lines. In localities where there is no timber, monuments of earth or rock may be erected, but not in the case of the legal posts marking the corners. These must be as shown in Fig. 4. Any location made on Sunday or any public holiday shall not for that reason be invalid, any law or statute to the contrary notwithstanding. The free miner on locating a placer claim must record the same in the office of the Mining Recorder for the Mining Division, within 15 days if located within 10 miles of the office, and one additional day is allowed for every 10 miles additional. The application for such record shall be under oath. Any claim not recorded within the prescribed time shall be deemed to be abandoned. A free miner, having duly located and recorded his claim, is entitled to hold the same during the existence of his record or re-record of such placer claim.

Every placer claim must be represented and worked in *bona fide* by the holder or some person in his behalf, continuously, as nearly as possible, during working hours, and is deemed abandoned and absolutely forfeited when it shall remain unworked for a period of 72 hr., except during the close season, lay-over or leave of absence, or during sickness, or for some other reasonable cause shown to the satisfaction of the Gold Commissioner. A leave of absence for one year is obtainable upon giving the Gold Commissioner satisfactory evidence that such is necessary, or upon the application for such leave being signed by all the holders of the claim or set of claims.

Every free miner "shall, during the continuance of his certificate but not longer, have the right to enter, locate, prospect and mine for gold and other precious metals upon any land in the province, whether vested in the Crown or otherwise, except upon government reservations for townsites, land occupied by any building, and any land falling within the curtilage of any dwelling house, and any orchard, and any land already lawfully occupied for placer-mining purposes, and also Indian and naval and military reservations." Previous to any entry being made upon lands already lawfully occupied, the free miner must give adequate security for any loss or damage which may be caused by such entry and shall make full compensation to the occupant or owner of such lands for any loss or damage which may be caused by reason of such entry; such compensation, in case of dispute, to be determined by a court having jurisdiction in mining disputes in British Columbia, with or without a jury.

Any free miner has liberty, at any period of the year, while actually prospecting or engaged in mining, to kill game for his own use. As a general right, every free miner is entitled to locate and record only one claim on each separate creek, bar or dry diggings, though he may hold any number of claims by purchase. In the event of a discovery of a vein or lode on his placer claim, he shall have no right to the same, unless he shall have located and recorded the ground as a mineral claim; and until he shall so locate and record such ground, as described in the Mineral Act, the same shall be open to any free miner to locate and record as a mineral claim in accordance with the provisions of that act.

A free miner, having located and recorded a claim and finding that it is of no value, may abandon it by posting notices to that effect on the four corner posts of his claim and recording such notice with the Mining Recorder, and forthwith shall thereupon be entitled to locate and record another placer claim upon other ground in lieu of the abandoned claim, and the abandoned claim shall then be open to relocation.

Leases on Occupied or Unoccupied Lands

A free miner in British Columbia is entitled, through the Gold Commissioner, to obtain a lease of any unoccupied and unreserved Crown land and even land already lawfully occupied, for placer-mining purposes for a term not exceeding 20 yr. Any free miner desiring to obtain a lease of any placer-mining ground marks out such ground by placing a legal post at each corner and by posting a notice on the post nearest to the placer claims then being worked in the immediate locality (if any), and within 30 days posts a notice in the office of the Mining Recorder, setting out: (1) The name of the applicant or of each applicant; (2) the locality of the ground to be acquired; (3) the quantity of ground; (4) the term which such lease is applied for. On making application, the free miner must deposit with the Mining Recorder a plan of the ground in triplicate and also deposit the sum of $20, which may go toward the payment of the first year's rent. Applications shall

not be greater than the following distances: In creek diggings on abandoned or unworked creeks ½ mi. in length; any other placer mining ground, 80 acres; but in no case must a lease extend along any creek or river more than 500 yd., creek diggings excepted. Leases are granted for placer mining only. A lease is not granted for any mining ground any portion of which is actually occupied by free miners, unless with the consent of such occupiers. Every lease provides for securing to the public reasonable rights-of-way and water, nor shall it prevent free miners from entering upon such ground to mine for veins or lodes.

The Gold Commissioner, with the sanction of the Lieutenant-Governor in Council, may grant a lease for any term not exceeding 20 yr. on the bed of any river below low-water mark for dredging purposes, for a distance not exceeding 5 mi. upon such terms as he shall think fit; provided always that every such lease shall reserve the right to every free miner or mining company to run tailings into such river at any point thereon, also to mine 2 ft. below the surface of the water at low-water mark, by putting in wing-dams, whether such miner shall locate before or after the date of such lease, nor shall the holder of a dredging lease interfere with free miners from constructing wing-dams into any such bars, banks or benches for the purpose of conducting mining operations, either by sluice or rocker. It is not lawful, however, for any free miner to construct wing-dams within 1,000 ft. of any dredger while working nor to obstruct any dredger in any manner.

Brazilian Monazite

Owing to the war the mineral production of Brazil is attracting more attention in the United States and Great Britain than seemed likely a short while since, says the *Mining Journal*, Oct. 2, 1915. In particular, the high price of monazite is bound to attract attention to all known deposits.

The export of monazite from Brazil is the subject of a concession to a French banker, M. Chouffour, for a period of 15 years dating from 1912. Of the profits 50% goes to the Government, in addition to a royalty rising to £120,000 when a stipulated tonnage has been shipped. According to official particulars, a stock of about 8,000 tons was held in Hamburg shortly before the war. Previous to the control acquired by the French Syndicate, the exploitation of the deposits was shared by two concessionaires, who fixed the price of thorium oxide at £5 15s. per unit.

The best-known deposits are those of Bahia, a concession over which was first granted to a Mr. Gordon in 1896. There are also important deposits in the State of Minas Geraes, more especially at Corrego da Onca, Dattas, as well as in the Casa and Jequitinhonha Rivers. A dressing plant is employed on the Parahyba River, where the sands are dressed on Wilfleys and the concentrates passed through magnetic separators to remove the iron in the sands. The raw material contains about 2% of thorium oxide, and the plant has a capacity of about 50 tons per month. Previously the cost laid down in Hamburg was put at between £15 and £20 per ton, and the value of the concentrate £28 15s. Exports in recent years have been: 1910, 5,437 tons; 1911, 3,686 tons; 1912, 3,398 tons.

Physical Control of Employees

The physical examination of employees to prevent the placing of unfit men in responsible positions has been instituted by many firms and corporations. It has always been attended with good results so far as efficiency in the work and satisfaction to the employee have been concerned; nevertheless, the practice has always been more or less opposed by the laborers themselves. In instituting the practice at the works of the Nevada Consolidated Copper Co., the authorities have taken pains to explain the reasons for doing so and the effect it will have upon employees. This explanation is so clear and reasonable that it is worth while reproducing here.

Men seeking employment, or having secured positions through the employment department, will be put to work "subject to medical examination." It will be required of every man employed to submit himself for physical examination immediately upon entering the service of the company, or during the time he is seeking employment if he so desires.

It will also be requested that employees now on the payroll shall take advantage of the opportunity to be examined. This task of examining employees will be commenced at once and will be spread over such period of time as may be necessary to its accomplishment, taking into consideration the convenience of the medical department and of employees. Employees need not worry over the result of physical inspection, nor need they horrow any thrills of terror of its "hurting" them in any way, physically or financially, in the assurance that no man now on the company payroll will suffer the loss of employment because of any ailment or physical defect; and in the further assurance that the results of individual examinations will not under any consideration be made public.

Nor will men now in the employ of the company who may take the examination be requested or required to sign any release or undertaking which will affect in any way their present hospital agreement or existing relations with the Nevada Industrial Commission.

It is intended that such examination as will be made shall be of as great, if not greater, benefit to each individual than it will be to the company. It will be practically in line with the scheme of the big life-insurance companies, which are making provision for free medical examination for their patrons and urging all their policy holders to submit to medical examination at least once a year. The object is to enable men to anticipate and ward off the approach of physical ailments, on the theory that "a stitch in time saves nine."

So far as the company is concerned, it is a safety-first proposition, a measure to promote accident prevention by trying to fit a man to a job wherein he will not be a menace to himself or to his fellow-workers. Relatively speaking, the hazards of every workman's occupation are affected by many elements of chance, human error, negligence and ignorance—but there is no reason why an employee should be subject to the further danger, the unseen, invidious menace of a fellow-employee's physical unfitness for his job. You, Mr. Miner, would not like it, would you, to risk your life daily on a cage controlled by a hoist engineer who might be subject to heart disease and who might collapse at any moment and drop you into the sump or drag you up into the sheaves. You would not like it, would you, Mr. Smelter-man, if a dinkey engineer should run amuck with his engine and a train of molten slag around the yard, endangering the lives of employees, because he could not see or was unable to determine the color of signal flags or lamps? You, Mr. Millman, would not want to work around a machine or machinery operated by a man who was not thoroughly fit physically, as well as mentally, to control that machine in case of emergency, would you? If hazards of this nature can be done away with, you would be willing to help, wouldn't you?

Many of the employing industries in this country and in Europe have required their medical departments to render this service, and not one word of protest has been made by employees, because men have come to see and understand that physical examination has largely eliminated a serious hazard in their daily work, a hazard to which they might otherwise, unknown to themselves, be subject.

Russian Nickel Deposits in the Urals, which have not heretofore been worked on account of the low grade of the ore, are now being exploited. The ore mined is being treated at the Redwinsk smelting works, which are reported to be turning out at the rate of 600 tons yearly of nickel matte.

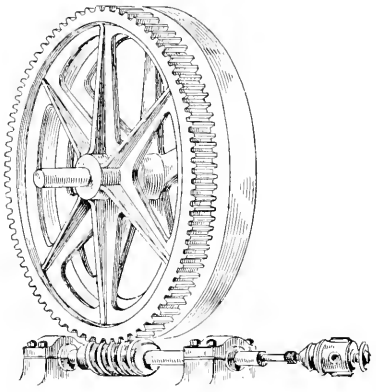
Details of Practical Mining

Facing-Off a Brake Wheel

By A. E. Hall*

The accompanying sketch shows a scheme used for surfacing off a brake wheel without dismantling the hoist to any extent. It sometimes happens that a job of this sort must be done around a mine, and usually the machinery for handling a piece of this size is not to be had, so that the wheel would have to be returned to the factory for repairs.

The brake band in the present case was lined with asbestos blocks which were bolted to the band. The blocks became worn, and the bolts cut into the brake wheel. When the brake was repaired the wheel had to be surfaced.



DEVICE FOR TURNING BAND WHEEL

There was no machine tool big enough to take the wheel for machining and besides there would have been the trouble of removing the wheel. There was no small cog-wheel on hand, and the machine shop was not equipped to make one. We were, however, able to make a worm gear with teeth only about ½ in. high. The teeth on the large drive wheel are about 3 in. The small teeth on the worm prevented any binding. The whole of the tooth on the drive wheel was never engaged by the worm teeth, but only a part of the tooth. The worm was mounted on a shaft supported on two bearings, as shown, and the shaft was extended at one end and shanked to fit an air twist drill such as most mines have in their shops.

For the purpose of facing the band-wheel one of the lathes from the machine shop was moved to the power house. The whole lathe was moved, including the frame; simply taking the legs off. The frame of the lathe was secured to the base of the hoist. With this arrangement it was possible to move the lathe-tool, by its own carriage and feed screws, across the face of the slowly turning band-wheel.

The hoist was turned by means of the air drill set on the shanked shaft of the worm gear which turned the main drive wheel. This is a fairly large hoist with three drums 5 ft. in diameter. The same idea can be applied to any hoist, and by making the worm gear correctly, the hoist can be made to turn at the desired speed.

*Creighton Mine, Ontario.

Constructing a 70-Mi. Water Conduit in Alaska

The construction of a conduit comprising 21 mi. of flume, 37 mi. of open ditch, and 12 mi. of pipe was the subject of a paper recently presented by H. H. Hall before the San Francisco Association of Members of the American Society of Civil Engineers.

The conduit leads from the Ogelvie range of mountains southwesterly to the Klondike mines near Dawson City, Alaska. Its purpose is to convey 125 sec.-ft. of water, or about 80,000,000 gal. per day. The conduit was constructed under separate organizations during three seasons of about 120 days each (1907-1909). Ditch construction was used wherever possible—7 ft. wide on bottom, 1½:1 slope, and 3½ ft. deep, with a gradient of 4 to 7 ft. per mi., the greater portion being 6 ft.

The right-of-way was first cleared of trees and the moss scraped off, as fast as it thawed, with teams and slip scrapers. The latter work presented the most troublesome problem from a construction standpoint owing to the uneven thawing of the muck and the consequent miring of the horses. Thirty miles of ditch were dug with six 30-ton steam shovels, the remainder with horse scrapers. As the shovels required a working space at least 16 ft. wide, no side-sloping was done with them. Small patches of frost were removed with 40% dynamite, but the larger patches were passed over, and after thawing were taken out with scrapers.

The record performance for one shift was 410 ft. of ditch, or about 1,200 cu.yd., with an average performance of 14.7 ft., or 51 cu.yd. per working hour. The season was from Jan. 15 to Oct. 15, with work usually slow the first and last weeks. The finishing gang followed the shovels—truing the grade, sloping the banks, clearing the berms, building a path along the top of the soil bank for watchmen, and constructing turnouts and overflows alternately every half mile. Common labor was paid $4 per day and board.

Mr. Hall stated that under operation the ditch had proved satisfactory, leaks being caused usually by ice seams.

Flume construction was adopted where the side slopes exceeded 15 deg. or where the muck was over 2 ft. thick. The flume construction was of the board-and-batten type, 6x4 ft. in cross-section, and built of native lumber, made up in 16-ft. sections and set on trestle bents of hewn timber placed 8 ft. on centers. Most of the bents were carried on mudsills, laid below the black muck (about 4 ft. deep), great care being taken not to disturb the moss

blanket unnecessarily, and to replace it as quickly as possible over the backfillings in order to preserve the ground in a frozen condition.

It was attempted to found some of the bents on piles driven into earth that had previously been thawed out by means of 16-ft. miner's steam points. In this manner the moss was broken only to admit the pile. Where the depth of muck would require very deep mudsill pits, the experiment was tried of placing gravel ballast directly on top of the moss and laying the flume stringers on crossties.

According to Mr. Hall, several years' operation of this flume has shown that the pile foundation is the best. Mudsill bents show continual settlement, caused by water flowing down the posts (either from the flume or from natural drainage) and thawing out the substrata.

Pipe lines were employed for pressure sections. For pressures not exceeding 200 ft. redwood stave pipe was used; for over 200 ft. or less than 1,000 ft., standard-riveted; for over 1,000 ft., lap-welded steel pipe. One section was constructed of spiral riveted pipe with patent bolted couplings.

In operation it has been found that the wood pipe has given considerable trouble, owing to the fact that between Oct. 1 and June 1 lines are drained and not used. The sand and gravel carried by the ditch water have worn the bottom staves badly. All intakes are now provided with sand boxes. Accumulations of ice at the discharge ends have caused considerable trouble by increasing the pressure on sections of the pipe. On high-pressure lines the sediment cuts the steel rapidly, and in one instance a ¾-in. rivet was cut away in two weeks.—*Engineering News.*

Hints on Loading Drill Holes

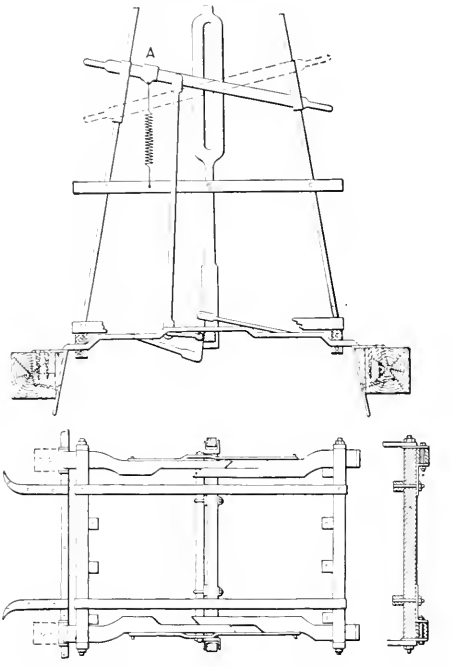
In loading short holes with a tamping stick, many blasters make a mark or notch on the stick, to indicate the distance from the collar of the hole to the top of the pocket or chamber. By this means they can tell when the pocket is loaded and when the charge begins to raise in the borehole. It is also a good idea to make a mark, or place a rubber band around the tamping stock, opposite the collar or mouth of the hole when the stick rests on the top of the charge when finished. The distance between this mark and the end of the tamping stick will give the amount of tamping in the hole so that in the event of a misfire it will be possible to remove nearly all of the tamping without danger of digging into the explosive.

The tamping stick, of whatever material, should not be a close fit in the borehole, as in loading holes full of water, where the tamping stock fits the borehole snugly, misfires have occurred, in tamping the hole, from the piston effect forcing the water into the electric blasting cap.

In loading deep well drill holes where it is not practicable to use a pole, a tamping block of hardwood attached to a rope is used. This block should not be weighted unless the holes have water in them. When weighted, a hole of about 1½ in. diam. is bored in the center of the block. A quantity of molten lead or babbitt metal is then poured in and the opening plugged with a wooden plug in such a way that no metal is exposed. These plugs are usually about an inch less in diameter than the diameter of the drill bit and from 3 to 4 ft. long. The rope for convenience and safety is passed over an open block or pulley, supported by a tripod 7 or 8 ft. high over the center of the borehole.—*Du Pont Magazine.*

Automatic Landing Chairs

An arrangement of automatic landing chairs devised by John Martin, of Taviche, Oaxaca, Mexico, which proved very satisfactory at the San Juan mine of that place, is described in the *School of Mines Quarterly.* The operation of these chairs is evident from an inspection of the sketch. A weight or spring at *A* automatically withdraws the chairs when the cage is raised and its weight taken off from them. The cage man holds the lever against the action of the weight or spring until the protruding chairs rest upon the landing and when stopping at a station, they are held in that position by the weight of the cage. The advantage claimed is that this type avoids the expense and danger of having sets of chairs at each of the levels from which hoisting is being carried on.



AUTOMATIC LANDING CHAIRS

Illuminating Powder Magazine*

The most suitable method of illuminating a magazine is by incandescent lamps with reflectors, set at some distance from the explosives. To require this, however, would work a hardship on mines that have no electric-light service. The portable electric lamp is equally safe, but is not yet sufficiently well developed to be practicable. The portable acetylene lamp is the most dangerous device

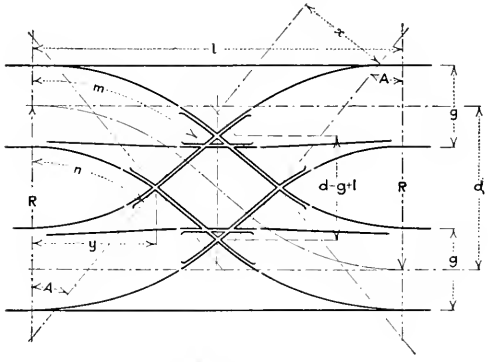
*Bulletin 75, U. S. Geological Survey.

for this purpose; the simple candle is a close second. The large acetylene lamp set some distance from the explosives is not very unsafe, but is not wholly reliable. It is strongly recommended that electric lighting be used.

Calculating Diamond Crossover for Shaft Bottom

In reply to a question as to how to put in a crossover, at the bottom of a shaft, with four frogs, *Coal Age* gives the following, the data given being the gage of the tracks (42 in.) and the distance between the two inside rails (42 in.):

The only dimensions given in this case are the gage of the track ($g = 3.5$ ft.) and the distance between track centers, which is twice the gage, or $d = 2 \times 3.5 = 7$ ft. In order that such a crossover can be operated successfully, it is necessary that the two frogs on the straight rails of the two tracks shall be constructed, as shown in the accompanying figure, with a small triangle of solid iron in the center of the frog. The purpose of this is to sufficiently separate the three points where the gage lines of the three rails cross each other. It will be sufficient if the gage lines of the two switch rails cross



A DIAMOND CROSSOVER

each other 6 in. inside of the gage line of the straight rail. This will make the distance measured straight across the rails, between the two points where the gage lines of the switch rails cross each other, $d - g + 1$, as indicated in the figure. All the dimensions in the following calculation are made to gage lines.

The first step in the solution is to find the angle A, which subtends the curved rail of each of these switches. This angle is found by substituting the values for d and g in the formula

$$\cos A = \frac{g}{d - g + 1} \times \frac{3.5}{7 - 3.5 + 1} = \frac{3.5}{4.5} = 0.7778+$$

Hence, $A = 38^\circ\ 57'$.

The second step in the solution is to assume a convenient radius, say in this case $R = 10$ ft., and calculate therefrom the entire length of the crossover, from point of switch to point of switch, which is marked l in the figure. This distance is found by applying the principles of trigonometry, which gives the formula

$$l = 2\ R \sin A + \frac{d - 2\ R\ (1 - \cos A)}{\tan A}$$

Then, substituting the known values in this formula, gives for the total length of the crossover

$$l = 2 \times 10 \times 0.6286 + \frac{7 - 2 \times 10\ (1 - 0.7778)}{0.8083}$$

$$= 15.73\ ft.$$

Since the angle of curvature of each of the switch rails is $38^\circ\ 57'$ and the radius of the outer rail in each switch is $r_1 = R + \frac{1}{2}g = 10 + \frac{1}{2}\ (3.5) = 11.75$ ft., the length of the outer curved rail, indicated by m in the figure, is

$$m = \frac{38^\circ\ 57'}{180^\circ} \pi r_1 = \frac{38.95}{180}\ (3.1416 \times 11.75) = say\ 8\ ft.$$

The radius of the inner curved rail is $r_2 = 10 - \frac{1}{2}\ (3.5) = 8.25$ ft., and the length of this inner rail, indicated by n in the figure, is therefore

$$n = \frac{38.95}{180}\ (3.1416 \times 8.25) = 5.6\ ft.$$

The length of straight rail in the switches, indicated by x in the figure, is found by substituting the known values in the formula

$$x = \frac{l - 2\ R\ \sin A}{\cos A} = 15.73 - \frac{2 \times 10 \times 0.6286}{0.7778}$$

$$= 4.06\ ft.$$

The two frogs in the loaded and empty tracks respectively are located midway between the switches, or at a distance of $\frac{1}{2}l$ from either switch. It now remains to calculate the distance of the two frog-points lying between the tracks, or the distance marked y in the figure. This distance is measured on the line midway between and parallel to the two tracks, from the line joining the switches to the point of frog. This distance is calculated by substituting the known values in the formula

$$y = \sqrt{r_2\ (d - g) - \tfrac{1}{4}\ (d - g)^2}$$

Since the radius of the inner curved rail (r_2) is 8.25 ft., the frog distance at each end of the switch is

$$y = \sqrt{8.25\ (7 - 3.5) - \tfrac{1}{4}\ (7 - 3.5)^2} = 5.08\ ft.$$

It is possible to lengthen out this crossover by adopting a longer radius than $R = 10$ ft. The angle of curvature (A), however, remains constant, for the same values of distance between track centers (d) and track gage (g), as appears from the formula given for finding this angle. For example, for a radius $R = 15$, the length of this crossover would be $l = 19.27$ ft. It is also possible to have the crossover rails cross each other outside of the track rails instead of arranging to have them cross within these rails, as in the foregoing figure.

Blueprinting Typewritten Matter

It is often desirable to blueprint a typewritten sheet. Whether this can be accomplished satisfactorily depends on a very small kink which is not generally known. It is almost impossible to get a satisfactory blueprint from an ordinary typewritten sheet; but if, when the sheet is being written, a piece of carbon paper is put behind it so that the carbon transfers to the back of the paper, the typewritten sheet will give a perfect blueprint. This is because the impression of the typewriter ribbon is reinforced by the carbon on the back, neither one being heavy enough alone to give a satisfactory print.

Details of Milling and Smelting

Measuring Sand and Stone for Concrete Roads

Measuring sand and stone for concrete at the time it is loaded into wheelbarrows at the storage pile by the use of 2-cu.ft. measuring-boxes is called for in the specifications of the Coleman du Pont Road now being built in Delaware. The specifications are as follows:

Great stress will be laid on the method of measuring the materials used in the concrete. It will not be allowed to measure the materials in ordinary wheelbarrows unless each load is struck perfectly smooth with a straight-edge. This is to insure perfect proportions in the concrete. Contractors shall use measuring-boxes or other similar device if so ordered by the engineer.

The engineer so ordered, says *Engineering News*.

Bottomless boxes, or frames, are placed in a flat-bottomed wheelbarrow and filled with sand or stone. The

LOADING WHEELBARROW WITH CRUSHED STONE AND MEASURING LOAD AT SAME TIME

frame is then lifted up and the wheelbarrow wheeled to the mixer. In the accompanying view the boxes are being used to measure stone.

At first the contractors did not favor the boxes, but now, according to Charles Upham, chief engineer of the Coleman du Pont Road, Inc., they swear by them. A boxful does not overload the wheelbarrow.

Fluming Granulated Slag

Among the many improvements being introduced at the Washoe smeltery, Anaconda, Mont., is the handling of furnace slags by an electric railroad. Cars of 20-cu.yd. capacity will be hauled to slag dump by 40-ton Westinghouse electric locomotive using 500-volt current. The cars have one new feature—sides dropping outward in a plane with the floor of the car to form an extension that will dump material further from the track, thus preventing clogging of rails. This change became necessary as a result of the introduction of the flotation process. In the past, water from the concentrator used to granulate the slag previous to its being flumed to the slag dump, contained a great deal of slime that acted as a coating to the slag, so that water carried it a great distance over the dump. Now that slime is being re-treated, water sinks as soon as it strikes the slag pile, which, without its coat of slime, has become much more pervious and as a consequence accumulates rapidly at the discharge end of the flume. The new system of hauling is expected to solve the problem of spreading the slag over a larger area.

Tests for Screen Selection

By Fred Meinke, Jr.*

In running several old dumps through the Gold Bluff mill, at Downieville, Calif., it was found that the tailings ran unusually high. A 30-mesh screen was being used. This screen had been used in the mill before with satisfactory results, and it was also being used in the mills in the immediate vicinity. To find the cause of the high tailings, as well as the height of discharge and height of drop best suited to the ore, the following tests were made.

The screens used were No. 1, 30-mesh perforated tin, a 24-mesh No. 27 crimped-wire screen and a 27-mesh, No. 27 wire screen. Of these it was found that the 27-mesh, 27-wire screen gave the lowest values to the tailings with a decrease in tonnage which was not prohibitive.

The tests were made in a five-stamp battery of the 900-lb. type. A screen area of 6x48 in. was used. The stamps were dropped at 100 and the height of drop fixed at 7 in. The ore consisted of coarse hard quartz broken to 2 in. with very few fines. The values were mostly in free gold, so that inside as well as outside amalgamation was practiced.

In making the tests the tailings were run into a 46-gal. barrel and the time of filling noted. The water was then decanted, the pulp thoroughly dried and weighed, and the tonnage determined. Before each test the battery was run for a certain length of time in order to give the screen time to build up and the battery to get down to its normal output.

TONNAGE AND VALUE OF TAILINGS

Test No.	8-In. Discharge Tonnage	8-In. Discharge Tails	5-In. Discharge Tonnage	5-In. Discharge Tails
1 and 4—30-mesh perforated-tin screen	3.05	$1.30	3.48	$0.90
2 and 5—24-mesh crimped-wire screen	3.00	1.00	3.34	.40
3 and 6—27-mesh crimped-wire screen	2.90	.80	2.97	.20

The first three tests—Nos. 1, 2 and 3—were made with an 8-in. discharge and gave an average value of $1 for the tailings. In making the next three tests—Nos. 4, 5 and 6—the discharge was lowered 3 in., making it 5 in. With this set of tests the tailings averaged 50c., a saving of 50c. over the first tests.

*Mining engineer, Downieville, Calif.

Comparing the individual tests, it is seen that the tonnage varied but little with the different screens and the high discharge, there being only 0.1 ton per stamp difference between the 24- and 27-mesh screens. This is easily accounted for by the sizing tests, which showed 75% of the pulp passing through 80-mesh. This indicates that the size of opening or character of screen had but little to do with the size to which the ore was crushed. The particles, when fine enough, are simply held in suspension by the water and are carried out through the screen openings.

With the 5-in. discharge there was a marked splash against the screen and, as the tonnage shows, there was a greater amount put through with the coarser screens. There was an increase of 0.37 ton per stamp between the 24- and the 27-mesh screens.

SCREEN SIZING TESTS

	With 8-In. Discharge			With 5-In. Discharge		
	No. 1	No. 2	No. 3	No. 4	No. 5	No. 6
Screens	%	%	%	%	%	%
Through 100	49.2	51.0	51.7	42.9	38.4	50.9
On 100	24.0	26.3	26.0	23.4	24.6	26.9
On 80	5.7	5.4	5.5	4.9	10.7	6.29
On 60	4.9	6.0	4.5	6.0	6.7	6.9
On 50	7.9	7.5	6.8	14.5	10.9	6.74
On 40	8.3	3.8	5.5	8.3	8.7	2.3

Tests Nos. 1 and 4, 30-mesh perforated-tin screen. Tests Nos. 2 and 5, 24-mesh crimped-wire screen. Tests Nos. 3 and 6, 27-mesh crimped-wire screen.

The sizing tests were made to find out if the loss in values was not on account of excessive sliming due to the high discharge. Although there is no marked difference between the percentages of pulp that passed the 100-mesh with the high and low discharge, these assays showed a greater value with the high than they did with the low discharge, thus proving that the increase of slimes was causing the loss. The fine particles of gold go off in the water without coming in contact with the mercury inside the battery or the amalgam on the plates.

Another test was made to show the increase in tonnage with an increase in the height of drop of the stamps. The battery running with an 8-in. discharge and a 6-in. drop produced 2.66 tons per stamp. With the same screen and discharge, but with a 7-in. drop, an increase of 1 in., the battery produced 3.05 tons per stamp, or an increase of 0.39 ton per stamp in 24 hours.

Some Data on the Burning of Powdered Fuel

In the *General Electric Review* for October, 1915, Arthur S. Mann gives some notes on the use of powdered coal. A hot stream of coal and air driven at high speed against a wall will cut it out—a low-fusing-point brick is melted down, a refractory brick is cut away mechanically. He has cut away carborundum brick by misdirecting a fire that did not approach the melting temperature of the brick, but such action is unnecessary. The remedy is to avoid high velocity along the brickwork. If a wall must take the full force of the current, protect it with loose brick or pass the current of combustion air along its face, which will deflect and protect. An arch can always be treated in this way. Some of the combustion air is cut off from the burner and sent along on top and over it. The total volume of air used is not increased, and a reducing fire can still be carried; heat distribution is noticeably good.

The design and building of the furnaces is an undertaking that calls for a high class of engineering skill. Feed, volume and current must all be considered. Sizes and areas influence the generation and distribution of the heat. The position of egress ports, if many, may defeat the purpose of the furnace. It does not do to build a furnace in the haphazard way of "apply a burner somewhere, and if it does not work, put in enough fuel to make it work." There is probably no other fuel so sensitive to correct use as is coal dust.

Some fuels can be burned without care on the part of an operator. Gas is one and oil virtually another. There is no economy in such ways, but the furnace is undeniably hot. Powdered fuel may run all day with no change in adjustment, but the fire should be looked at every half-hour or so. Slag and some fine ash are always forming, and it is well to know where these are going. On the other hand, a wrong adjustment of either coal or air makes itself apparent. Powdered coal burns best with 200 cu.ft. of air per pound of fuel. It can burn and burn clearly with 160 cu.ft. and even less, but the extra air pays. As the supply exceeds 200 cu.ft., efficiency begins to fall. There is even a noticeable loss at 208. The eye cannot discriminate between a 200-ft. and a 208-ft. fire, but it can recognize the 250-ft. or even a 220-ft. blaze. There is a marked change in appearance and unless a cutting fire is really wanted, there is no excuse for such bad mixture. The powdered-coal fire begins to snort and wheeze when it has too much air.

Cementing Out Copper on Copper-Nickel Matte

In a recent patent (U. S. pat. 1,128,313) of N. V. Hybinette of Christiansand, Norway, assignor by mesne assignments to the National Trust Co., Ltd., of Toronto, Canada, it is stated that copper can be cemented out of copper-nickel solutions on an anode of copper-nickel alloy containing 4 to 8% of sulphur, providing that the anode has been previously corroded in an electrolytic bath. Where an anode has not been corroded previously, this is at present an impossibility. It furnishes a convenient method of depleting a copper-nickel solution of copper while simultaneously enriching it with nickel, by the use of a purely chemical reaction.

The anode itself and its production by blast-furnace smelting are covered by Mr. Hybinette's U. S. pat. 1,128,316.

Baggaley Method to Neutralize Smeltery Fumes

Ralph Baggaley has been granted a patent (U. S. pat. 1,135,488) for neutralizing smeltery fumes and preventing the escape of dust resulting from the treatment of sulphide ores by cooling the fumes to below 300° F., bringing them in contact with ore or other value-bearing material and passing the gases through a neutralizing bath. One method of carrying out the process is to deliver the fumes into a body of neutralizing material such as a bath of milk of lime. It is also proposed to cool the gases by passing them through a multiplicity of cooling flues. This idea may be applied to the gases and fumes from converters by passing them through moving bodies of ore and in contact with fresh ore material to preheat them, depositing thereon the metallic particles and heat contained in the fumes, and then passing the gases to a neutralizing bath.

Correspondence and Discussion

Civilian Engineers and Military Service

The recent editorial[1] on "Civilian Engineers and Military Service" contains valuable observations that deserve earnest consideration by engineers generally. Indeed, it is to be regretted that the proposition of enlisting the civilian engineers into an army reserve corps could not have been broached a few months earlier, so that a greater number of engineers could have been induced to attend the Plattsburg training camps of last summer. Under the circumstances, the Plattsburg movement was not sufficiently advertised in engineering circles and the attendance of engineers at the camps was noticeably small in comparison with that of other professions. In the first two battalions of the "business men's regiment," with a combined strength of 1,200 men, during the August-September encampment, probably less than 1% were engineers of any branch, while physicians, lawyers, bankers and brokers were present in great numbers. Even diplomats were almost as numerous as engineers.

It is to be hoped that other, similar training camps in the future may attract a greater attendance by engineers, even by those who may not be prepared to identify themselves with a permanent army reserve corps.

While the mining engineer, as you have pointed out, in a war emergency may prove useful to the army authorities because of his familiarity with matters of organization and administration and experience in handling large bodies of men, still in these very matters the army can give the engineer, and particularly the younger engineer, a valuable object lesson that may prove useful to him in his own peace-time pursuits. Apart from the "rudiments of military training," there was much to observe and learn at Plattsburg that was useful, both to engineer and ordinary citizen, in everyday life. The modern methods of camp sanitation and the instructions in hygiene and personal cleanliness of the soldier were highly interesting and alone well worth the time expended and the hardships endured. The system now used by the army for construction and care of camp kitchens, eating houses and latrines, with disposal of waste, etc., may well be adopted in many mining camps. Similarly also, the provision for general typhoid inoculation. The clean, airy, screened eating houses at Plattsburg, seating 125 men each, would have proved a revelation to some boarding-house bosses and proprietors of Chinese restaurants or other fly-infested eating places in our Southwestern mining camps.

During the nine days' maneuvers, when several regiments of the regular army, of all arms, participated with the "business men" in a combined force of over 4,000 men, with some 2,000 horses and mules, highly instructive demonstrations were furnished daily in the remarkably rapid and orderly manner of occupying and evacuating bivouac camps. The length of the column, with wagon train, was such that it required one hour's time to pass a given point, while on the march. But within less than half an hour of the arrival of the last detachments on the new camp site, the vast fields were occupied by the streets and abodes of an orderly community of more numerous inhabitants than even the neighboring towns; tents were raised in their allotted places, arms and equipment put away, wagons unloaded, horses and mules picketed and, best of all, company kitchens ready for business. Even more impressive was the early morning sight of the tented city disappearing, within less than one hour's time after the order to strike had been issued, leaving on the stubble of the field not a scrap of paper, nor a vestige of human, animal or kitchen waste.

These maneuvers also furnished an excellent demonstration of the value of motor trucks and motor cycles in warfare and on a larger scale than any previous army maneuver in this country. The motor trucks were used for a number of special purposes such as for searchlights, radio apparatus, machine guns, field hospital and ambulance and water wagon, but the 2-ton Autocar trucks that were used to transport the commissary supplies and company baggage of the "business men's regiment" were decidedly popular with the latter organization. These cars went wherever the mule wagons could go—on sandy hill roads, over fields and ditches, boulders and hummocks—and they made two or more trips for each trip of the mule wagons over the same distance. Sometimes, when a bridge would break down, a preceding truck would pull the other out of the hole and the succeeding ones turn into the creek, leaving the bridge to be repaired in a substantial manner by the following engineer train.

Of great interest, also, were the daily evening lectures on military subjects by officers of the regular army, each a specialist in his particular field. On one of these occasions the regiment had the pleasure of listening to an address by President H. S. Drinker of Lehigh University, who represents the A. I. M. E., on the "Joint Committee of the National Engineering Societies on the National Reserve Corps of Engineers" and also the Associated Student Societies now working to spread the propaganda of the Plattsburg idea.

[1] "Engineering and Mining Journal," Sept. 11, 1915.

Why Not Call Things by Their Right Names?

In reading the article on "Calamine Mines of Sardinia," by Charges W. Wright, published in the *Journal* of Oct. 16, 1915, I was somewhat surprised to run onto the sentence, "The term calamine is applied to the ore, though technically it is essentially smithsonite." Inasmuch as the ore is "essentially smithsonite," would it not have been much better to have so designated it in the title of the paper? This would have avoided the chance of a misconception of the nature of the zinc ore in the mines described and would have made the title much more satisfactory to the bibliographer. I am aware that some good writers use the terms *calamine* and *smithsonite* interchangeably,

probably following the custom of the miners, but for the sake of clearness such usage should be avoided.

Nashville, Tenn., Oct. 21, 1915. A. H. PURDUE.

[Professor Purdue raises an old question, namely, as to the correct definition of the oxidized minerals of zinc. In spite of the pronouncement of the United States Geological Survey to the contrary and the testimony of the government expert witnesses in the calamine tariff litigation, the term calamine has been used commercially and metallurgically for more than 100 years to include both the carbonates and both the silicates of zinc, and it was so used before mineralogists had made any distinction among these minerals. Mr. Wright, who is a mining and metallurgical engineer, apparently described the Sardinian ore from the professional viewpoint. Among zinc miners and smelters there would not be the least misunderstanding of what he meant. There are times, however, when the absence of a precise name for certain of these minerals is troublesome. What the mineralogists ought to do, we think, is to get together, talk the thing over, discard calamine as the name of a mineral species and formulate definite names for the hydrous silicate and the anhydrous carbonate. There is not any misunderstanding about willemite (the anhydrous silicate) or hydrozinkite (the hydrous carbonate). If mineralogists should agree to call the anhydrous carbonate smithsonite and the hydrous silicate hemimorphite—using Dana's second name—confusion would disappear.—Editor.]

Newfoundland's Mineral Resources

In an article by P. B. McDonald on "Newfoundland's Mineral Resources" in the *Journal* of Oct. 23, I find the statement that there are "12 seams of ore (iron) interstratified with shales and sandstones." This refers to the Wabana beds of iron ore on and adjacent to Bell Island, Conception Bay.

There are three chief beds of iron ore that outcrop on Bell Island and exist under the adjacent ocean floor. In addition to these three are a few others, of much less moment, that may be classed as parts of the three, separated from them by shale partings of greater or less thicknesses, or as entirely separate and distinct beds that may reach the dignity of minable seams in places yet to be discovered. It is difficult to classify these thinner seams, but all of them appear to be parts of certain definite ferruginous strata, the main development of each of these strata being one or the other of the three chief beds before mentioned. It would seem, therefore, that the minor seams are but portions of the chief beds. Each ferruginous stratum is separated from the other by considerable thicknesses of shales and sandstones devoid of iron.

The lowest of the three beds is that which is called the "Dominion"; above it lies the "Scotia" bed, and above that the "Upper" bed. The first outcrops along Bell Island for a length of about four miles and has a thickness varying from 4 to 14 ft. and an average of 10 ft. of clean ore. The Scotia bed outcrops for about two miles and has an average thickness of about 7 ft. Still higher is the upper bed, and its outcrop is about a mile. It is of varying thicknesses and, where now mined, runs from 4 to 8 ft. At the breast of the Nova Scotia company's submarine slope, 7,500 ft. out at sea, the Dominion bed shows in places a thickness of 28 and 30 ft., almost without shale partings, and this immense thickness forms a most impressive sight.

Mr. McDonald quotes the colonial geologist as estimating a total of three billion tons for the amount of this iron ore of Conception Bay and Bell Island. I notice that some estimates, notably that of E. C. Eckel, are much higher. The geologic work of Hayes and VanIngen, however, seems to indicate the probable tonnage to be somewhat less than either of the mentioned estimates, and I have considered that there is not far from two billion tons in the Dominion and Scotia beds. But whether there are two thousand million or five thousand million tons in this deposit is of little economic interest to the present generation. The deposits are of the utmost importance and of great moment in the consideration of the future of the Atlantic-coast iron trade.

DWIGHT E. WOODBRIDGE.

Duluth, Minn., Oct. 29, 1915.

NEW PATENTS

United States patent specifications listed below may be obtained from "The Engineering and Mining Journal" at 25c. each. British patents are supplied at 40c. each.

ALLOYS—Improvements in the Manufacture of Steel Alloys. Soc. Anon. des Acieries et Forges de Firming, Firming (Loire), France. (Brit. No. 3,427 of 1915.)

ALUMINUM—Process of Treating Aluminum Screenings, Dross, Slags, or Analogous Aluminous Materials. James Wright Lawrie, Aurora, Ill. (U. S. No. 1,156,606; Oct. 12, 1915.)

AMALGAMATOR. Erastus B. Bennett, Denver, Colo. (U. S. No. 1,157,836; Oct. 26, 1915.)

CHROMIUM OXIDE—Manufacture of Chromium Oxide. Albert Edward Gessler, Clifton, N. Y. (U. S. No. 1,158,379; Oct. 26, 1915.)

CHROMIUM SALTS—Producing Chromium Salts. Johann Heinrich Boner, Ludwigshafen-on-the-Rhine, Germany, assignor to Badische Anilin & Soda Fabrik, Ludwigshafen-on-the-Rhine, Germany. (U. S. No. 1,157,668; Oct. 26, 1915.)

CRUSHING—Ore-Grinding Machine. Charles O. Michaelsen, Omaha, Neb. (U. S. No. 1,158,259; Oct. 26, 1915.)

DRILL—Percussive Drill. Charles C. Hansen, Easton, Penn., assignor to Ingersoll-Rand Co., Jersey City, N. J. (U. S. No. 1,154,921; Sept. 28, 1915.)

DRILLS—A Débris-Removing Device for Percussive Rock Drills. G. Mairet, London, England. (Brit. No. 24,109 of 1914.)

DRILLS—Improvements in Power-Driven Rock Drills. M. Kellow, Penrhyndeudraeth, N. Wales. (Brit. No. 13,067 of 1914 and 11,564 of 1915.)

ELECTRIC FURNACE. Ernesto Stassano, Turin, Italy. (U. S. No. 1,157,819; Oct. 26, 1915.)

ELECTRIC FURNACE. Sigmund Guggenheim, Berlin-Wilmersdorf, Germany. (U. S. No. 1,157,691; Oct. 26, 1915.)

FILTERING APPARATUS. David J. Kelly, Salt Lake City, Utah, assignor to Kelly Filter Press Co., Salt Lake City, Utah. (U. S. No. 1,158,056; Oct. 26, 1915.)

FILTERING PROCESS. David J. Kelly, Salt Lake City, Utah, assignor to Kelly Filter Press Co., Salt Lake City, Utah. (U. S. No. 1,158,055; Oct. 26, 1915.)

FIREPROOF UTENSILS—Process for the Manufacture of Fireproof Utensils from Refractory Oxides. Hans Arnold, Charlottenburg, Germany, assignor to the Firm of Dr. O. Knöfler & Co., Plötzensee, near Berlin, Germany. (U. S. No. 1,157,682; Oct. 26, 1915.)

FLOTATION—Apparatus for Concentrating Minerals by Flotation. George C. Stone, New York, N. Y., assignor to The New Jersey Zinc Co., New York, N. Y. (U. S. No. 1,156,041; Oct. 5, 1915.)

FLOTATION—Improvements in or Relating to the Separation of Metallic Sulphide Ores. Minerals Separation and de Bavays Processes Australia Prop., Ltd., Melbourne, Australia. (Brit Nos. 19,373 of 1914 and 19,374 of 1914.)

FLOTATION—Separation of Metallic Sulphides from Ores. Thomas Mackellar Owen, Sydney, N. S. W., assignor to Edward William Culver, Sydney, N. S. W. (U. S. No. 1,157,176; Oct. 19, 1915.)

HYDRAULIC NOZZLE. William A. Doble, San Francisco, Calif., assignor to Pelton Water Wheel Co., San Francisco, Calif. (U. S. No. 1,157,853; Oct. 26, 1915.)

INGOT MOLD. Harry E. Sheldon, Pittsburgh, Penn. (U. S. No. 1,158,311; Oct. 26, 1915.)

IRON-ORE TREATMENT—Process of Extracting Iron from Its Ores. Herbert Haas, San Francisco, Calif. (U. S. No. 1,156,775; Oct. 12, 1915.)

August Foreign Trade in Metals

Advance reports from the Department of Commerce give imports and exports of the principal metals in the United States during the month of August, which are of special interest at the present time.

Imports and exports of copper in August were as follows, copper in pounds, ore in tons:

	Imports		Exports	
	Tons	Contents	Tons	Contents
Ore and concentrates	50,511	10,890,762	7,274	272,218
Matte, etc.	1,877	954,439	..	.....
Unrefined in bars, etc.	....	18,225,578	....	.....
Refined bars, plates, etc.	....	439,050	....	37,240,920
Old and scrap	....	592,569	....	7,364
Total		31,102,398		37,520,502

The wire included in the total exports was 2,907,110. In addition to the exports above manufactures of copper valued at $794,069—quantities not given—were exported.

Imports of lead into the United States in August in all forms are reported by the Department of Commerce as follows, ore in tons, bullion and lead in pounds:

Lead ore, tons:	Ore	Lead, Lb.
Canada	107	103,000
Mexico	5,883	1,089,071
Peru	464	289,331
Total	6,454	1,481,402
Lead bullion, lb.:		
Mexico	8,643,080	8,439,972
Peru	20,385	19,376
Total	8,663,465	8,459,348
Lead, pigs, bars and old		15,820
Total lead imported		9,956,570

The total imports reported up to the end of July were 59,312,137 lb., making the total for the eight months ended with August 69,268,707 lb., or 34,634 short tons.

Imports and exports of zinc in all forms are reported by the Department of Commerce for August, as below; ore in tons, zinc in pounds:

Imports:	Ore, Tons	Contents, Lb.
Zinc ore, Canada	813	724,400
Zinc ore, Mexico	6,277	4,207,503
Zinc ore, Australia	524	587,412
Total	7,614	5,519,315
Blocks, pigs, etc.	.....	116,675
Total		5,635,990
Zinc dust		85,657
Exports:		
Pigs, bars, etc.		2,820,728
Plates and sheets		12,568,422
Total metal		15,389,150
Zinc dust		43,550
Zinc dross		732,785

The exports of zinc dust were all reëxports of foreign material. In addition to the exports given manufactures of zinc valued at $499,214 were exported.

Japanese Mine Output, First Half of 1915

The mineral production of Japan in June, 1915, was: Gold, 646,402 kg.; silver, 13,225,353 kg.; copper, 5,757,884 metric tons; iron, 3,999,841; coal, 1,413,838; sulphur, 6,051,507 metric tons; petroleum, 47,925,720 liters.

The total production for the first half of 1915 is given by the *Japan Advertiser* as follows: Gold, 3,728,413 kg., an increase of 19.9% over 1914; silver, 72,826,696 kg., an increase of 3.3%; copper, 32,746,382 metric tons, an increase of 4.5%; iron, 23,958,758 metric tons, a decrease of 28.8%; coal, 9,093,917 metric tons, a decrease of 9.1%; sulphur, 28,522,199 metric tons, a decrease of 6.1%; and petroleum, 227,295,940 liters, an increase of 18.6% over 1914.

Elm Orlu-Butte & Superior Apex Suit at Butte

BUTTE CORRESPONDENCE

The ore controversy between the Elm Orlu Mining Co. and the Butte & Superior Copper Co., which was on trial the past week in the Federal court in Butte, Judge George M. Bourquin presiding, involves an orebody variously estimated by the experts for the Clark (Elm Orlu) and the Butte & Superior interests at $15,000,000 to $20,000,000. It is stated that if Clark wins he will get practically all of the Butte & Superior vein and orebody lying west of the Blackrock shaft, which contains enough ore to keep the Butte & Superior mine and mill running at their present capacity for a year and a half.

The Clark contention is that the big Rainbow lode has its apex in the Elm Orlu claim, which lies south of the Blackrock and Jersey Blue of the Butte & Superior Co., and that on its strike to the east it forks, the northern branch entering the south side line of the Blackrock and passing through the claim and out of the north side line, thus giving to the Butte & Superior no extralateral rights to that vein. The main contention, however, is that the Rainbow vein, on its depth, dips north into the Jersey Blue and Blackrock claims and that the Butte & Superior has been mining on the Rainbow, or Elm Orlu vein, on its dip to the north, and that between 700 and 800 ft. of that vein under the Blackrock surface belongs to the Elm Orlu. The claim of the Butte & Superior, of course, is that it owns the apex of the veins upon which it is mining, known as the Jersey Blue and Blackrock veins.

Many of the most noted geologists and mining experts of the country and learned and experienced mining lawyers appeared in the case for one side or the other. In the complaint only a nominal sum is mentioned as the value of the ore already mined from the disputed vein, but should Clark get a judgment there will follow an action for accounting. By mutual agreement the Butte & Superior has stopped mining in the ground in controversy. Beside the disputed vein the Butte & Superior has other good ore deposits and is developing more.

Iron-Mining Fatalities Reduced Two-Thirds

The annual report of the mining inspector of St. Louis County, Minnesota, containing the major portions of the Mesabi and Vermilion Ranges has just been filed. It shows that 830,469 tons of iron ore was mined and shipped for each fatal accident.

The following tabulation is taken from the report and indicates the success of the "safety-first" movement inaugurated several years ago:

Year Ended June 30	No. Employed	No. of Killed	Fatalities per 1,000
1906	12,838	96	7.48
1907	15,525	81	5.21
1908	13,313	54	4.05
1909	13,206	61	4.56
1910	17,613	71	4.02
1911	19,981	78	3.90
1912	15,398	51	3.31
1913	16,048	44	2.75
1914	16,660	43	2.59
1915	11,436	24	2.09

Of the 11,436 men employed, 5,830 were in underground mining, 1,910 in openpit mining, 1,722 in stripping and 1,974 on surface work. The average wage paid miners was $2.96 per day.

Kyshtim Corporation and the Effect of the War

The profits of the Kyshtim Corporation last year showed a decline as the result of conditions arising out of the war. The company, however, now seems in a position to recoup these losses by reason of the stimulation of the demand for certain of its products. At the sixth annual meeting held in London recently, Chairman C. F. H. Leslie stated that the company's mines and plants in Russia were now in a position to produce under normal conditions 10,000 tons of copper per year. The war created certain new situations affecting the company and its operations. The company is erecting, at the request of the Russian Government, works for the annual production of about 8,000 tons of sulphuric acid. The cost of erecting this plant will be advanced by the Russian Government, and the first two years' output purchased at a price that is regarded as satisfactory. The company has also received orders from the Russian Government for pyrites, and has increased its output of this mineral to about 1,000 tons a week. From one-third to one-half of the employees have joined the colors, but notwithstanding this fact, the production of copper this year up to Oct. 2 was approximately 6,000 tons.

In 1914 the abnormal conditions increased the cost of producing copper by about £6 per ton. The profits on copper operations, according to the *Financial Times*, showed a decrease for the year of £67,000; from iron operations a decrease of £32,000; from forests a decrease of £3,500, and from barren pyrites a decrease of £2,500—a total decrease of £105,000. The net earnings for the year were were approximately 3s. per share as compared with 5s. during the previous year. The dividend recommendation was 1s. per share. Remittances to the English company in the form of gold and silver residues, the product of the electrolytic refinery in Russia, have finally become impossible owing to the order of the Russian Government prohibiting the export of gold-bearing residues. As there is no plant in Russia suitable for separating the refinery products, the directors of the Russian company are negotiating with the Ministry of Finance in Petrograd in regard to a solution of this problem. Nevertheless, since the beginning of the war the British company has distributed in dividends £250,000 without impairing the financial situation of the Russian operating company. The company's operations in 1914 were considerably hampered by the mobilization by the government of more than one-third of the regular employees of the company, the shortage of railway and other transport, and the commandeering of coal supplies. On account of the last circumstance, the company exercised an option on a coalfield it had been investigating. This is about 2½ miles from the railroad and is estimated to contain several million tons of coal above the 200-ft. level. Connections have been made with the railroad, and it is expected that in a few weeks this colliery will be able to supply all the coal required by the company.

During the 12 months ended April, 1915, the company extracted 352,000 tons of copper ore, but disclosed by development and drilling 558,000 tons, so that the ore reserves in April, 1915, were 2,667,000 tons. Since that date a new borehole at the Smirnoff mine has cut the lode at a vertical depth of 1,100 ft., or 500 ft. deeper than the previous depth proved at this mine. The east vein of massive pyrite was 6 ft. in width, and the west vein for 41 ft. contained nearly 3% copper and about 10s. per ton in precious metals. It was considered that this borehole had indicated an additional two years' life to the mine, or a total of approximately 10 years of ore reserves at the present rate of production.

Homestake Mine-Rescue Teams

At the third national field meet, held Sept. 22-24, at the San Francisco exposition, an interesting set of contests between mine-rescue and first-aid teams was held. There were 26 first-aid teams and 15 mine-rescue teams competing. Probably the most interesting of them

HOMESTAKE FIRST-AID AND MINE-RESCUE TEAMS

Reading from left to right, top row: A. E. Aldalo, J. F. Peters, J. Letcher, B. Hardwick, M. Ellis, Wm. Yeager. Bottom row: C. L. Ayer, captain, First-Aid team; R. W. Bonney, manager, Mine-Rescue team; Dr. F. E. Clough, manager, First-Aid team; C. A. Brooks, captain, Mine-Rescue team

all was the team representing the Homestake Mining Co., of South Dakota. This team won first place in the first-aid contest and fourth place in the mine-rescue competition. A photograph of the team is shown here.

California Oil in September

The California production of petroleum in September amounted to 7,370,430 bbl., a decrease from August of 300,000 bbl. The total shipments for 30 days in September, amounted to 7,718,807, as compared with 8,077,586 for 31 days in August. The amount of oil shut in was 18,000 bbl., the same as in August, and 500 bbl. less than in September, 1914. The amount of stocks Sept. 30 was 59,624,905 bbl., a decrease of 537,372 bbl. from August. This reduction in field stocks was insufficient to have an appreciable effect on the general situation, but it confirms the opinion of oil-trade experts that stocks of crude petroleum in pipe lines and field storage were being drawn upon to the extent of approximately 20,000 bbl. per day in September, because of the excess of shipments over production.

Field reports show that 30 new wells, with an initial output of about 10,000 bbl. per day, were completed in September; 17 of these wells are in the Midway-Sunset district. This is an increase of 18 new wells over August. The wells in active drilling in September numbered 145, a decrease of 7 from August. Drilling activity was due to obligations of leases. There were 6,438 wells producing in September, a total average daily production of 245,681 barrels.

Schedule of prices paid at the wells for crude petroleum remained the same as in the last four months.

Editorials

Revival of the Mining Industry

Unless all signs are fallacious, the mining industry of the United States is experiencing a real revival. This is not to say that it has been inactive or sick, for there has been scarcely a year during the last decade when there has not been an increase in the production of iron, copper, lead and zinc; but ever since 1907 there has been a sluggishness in gold and silver mining, an absence of interest in the development of new mines and an alarming decline in prospecting. Moreover, the troubles in Mexico during the last three or four years brought mining in that country to a standstill, seriously affecting the interests of American investors and manufacturers, engineers and operators.

Several things have combined to bring about a new and favorable turn in the mining industry. In the first place the huge demand—and consequent high prices—for copper, lead, zinc, antimony and quicksilver, due to the war, greatly stimulated the mining of those metals and required the services of a good many more men and the addition of a good deal of new machinery. Take the case of zinc smelting, for example. A very large sum has been invested in new plants since the beginning of 1915.

Similarly the extraordinary prices commanded by some of the rare ores, such as tungsten and molybdenum, sent hundreds of prospectors into the field to look for them. With tungsten ore selling at $2,000 and upward per ton, the discovery of a deposit yielding a carload or two is enough to give the lucky prospector a fortune. The *Journal* has heard of a case where samples from Mexico were exhibited to an adventurer in Arizona. He recognized them as wolframite and organized an expedition to go into the inferno of bandits and revolutionists to get some of it. His man came back with a cargo of 30 tons that sold for $75,000. Prizes like that inflame the prospector of '15 as nuggets of gold did the fortyniners. Not one out of a hundred, or a thousand, will be so lucky in tungsten, but some of the 99 or 999 are likely to stumble upon some previously unknown deposits of the other metals that may eventually develop into producing mines.

Other favorable conditions are developing, especially the reawakening of the spirit of speculation among the American people and the hopefulness as to restoration of law and order in Mexico.

The *Journal* has repeatedly expressed the opinion that there would be no general revival in the development of prospects and small mines, participation in the business by the thousands instead of by the few, until there had been a prolonged and successful bull movement in Wall Street. The great exploration companies and firms seldom develop mines. They are looking for sure things—huge deposits of ore developed by somebody else, too low in grade to be worked by any little concern, which they can make profitable by the use of immense capital and the application of professional skill. Such operations create but little semblance of activity in mining. What gives the tone is when hundreds of little companies are gambling in all directions upon the finding of ore. Ordinarily it is hard to find persons to go in for such gambling. Clergymen and widows are prone to it, but those classes alone are unable to keep the game going. As for the Guggenheims and mining capitalists of their ilk, anybody who tried to get them into a prospecting venture would probably receive the cold shoulder. They know too much and don't want to take chances. But let a promoter go around among his Wall Street friends who have just made a million or so in Bethlehem Steel or Crucibaker, and they will take a hundred-thousand-dollar chance on developing a mine without even asking what or where the mine is. In 1915 we have had for the first time since 1906-7 a bull market that has inflamed the popular imagination, that has aroused a speculative fever that already gives signs of spreading into mining.

As for the bearing of the Mexican situation upon the American mining industry, no dissertation is necessary. A mere statement that there seems to be a probability that stable government will soon be existent in Mexico is sufficient. Following that, the return of the mine operators, the reopening and reëquipment of the mines may be seen with the mind's eye. The resumption of mining in Mexico would alone be sufficient to work a revival in the mining industry of the United States.

International Gold Exchanges

Under the conditions that prevail in international trade it seems inevitable that from time to time there should be balances that can be settled only by the actual physical transfer of gold from one nation to another. These occasions arise in normal times, so that every year considerable amounts of gold have been shipped from New York to London or Paris, probably to be returned some months later. At the present time there is a specially striking illustration of this, the abnormal war conditions having brought about an extraordinary balance of trade in our favor. The great loan that has just been made here is partly an attempt to adjust matters through credit and to avoid further unusual shipments of gold.

We do not wish to discuss here the higher problems of finance involved in the loan transaction, but to call attention to a certain amount of waste and loss which is involved in this physical transfer of gold. The loss of interest during the period of transfer, the cost of transportation, the necessity of guarding and insuring the metal in transit, the danger of loss from theft or accident, the waste of metal by abrasion—all combine to make up a perceptible sum, which in the case of large shipments amounts to a considerable tax on the transactions. This cannot be avoided as long as we must cart our gold back and forth as the balance of trade fluctuates one way or the other.

There is also a further cause of loss of which we do not always take account. These transfers of gold are often necessarily made in coin that is foreign to the country in which it is delivered. A shipment of gold from Eng-

land to this country, for instance, may be all in American eagles, but more often it is all or in part in British sovereigns. Thus in a recent shipment of about $20,000,000, two-thirds was in British coin. Under existing American law foreign coin can be held and counted in current bank and treasury balances as gold bullion, but there are rather stringent regulations as to weight, allowance for alloy and other matters, so that bankers usually prefer to undergo the expense and trouble of recoinage. The case is very much the same when American gold coins are sent abroad. If it seems probable that they are to be retained in England or France for any length of time, a considerable part of them will be recoined into sovereigns or 20-franc pieces, notwithstanding the accompanying loss.

It has been proposed many times that this loss, or discount, might largely be avoided by the agreement of the chief commercial nations upon an international gold coinage. In advocacy of this suggestion it is argued that the values of an English sovereign, an American half-eagle, a French 25-franc piece, a German 20-mark piece, a Russian 10-ruble piece and a Japanese 10-yen piece are so nearly alike that a coin which would represent them all could be made with such slight variations from the original that the coinages of the various countries would not be perceptibly affected. It would not be necessary to change the names of the coins or to make more than very slight variations.

We are disposed to regard this idea, however, as impracticable, believing that careful consideration of it would bring to light as many difficulties as there are in the case of the proposal to discard the existing system of weights and measures in the English-speaking countries and substitute the metric system. What would be more to the point, we think, would be an international agreement respecting the fineness of the several coins and acceptance thereof, so that it would be unnecessary to remelt and recoin them so often after an exchange, merely through simpler regulations as to weighing and valuation.

Comparison of Crushing Tests

Some system for comparing crushing tests so as to give real information is badly needed. Many suggestions have been made, but none of them has met with universal approval. The difficulty of getting a satisfactory basis insures a welcome for every new plan. The latest is a suggestion by M. K. Rodgers, in a paper to the American Institute of Mining Engineers. The data Mr. Rodgers wants to include are these: Descriptions of the machines employed; the method and material used in foundations; the locality from which the rock or the ore was obtained and its geological, mineralogical and physical characteristics; power consumption of the machine running with no load and with full load, the units of power being 1 hp. per 24 hr.; the capacity of the machine in tons of 2,000 lb. per 24 hr.; the duty in tons per horsepower-day, and a careful statement of the screen analysis of both the feed and product, in accordance with the proposed A. I. M. E. standard-screen scale. It is proposed that whenever a rock-crushing test is reported, all of the factors mentioned shall be given in detail.

There is no doubt that Mr. Rodgers' suggestion ought to be acted upon, though it could be amplified. It does not go far enough. All operators are well aware that, aside from the factors mentioned, there are many others that have more or less influence upon results. They ought to be considered. Besides, there is not much profit in finding out what kind of ore you have by working it in a certain machine. It seems better to find out how good the machine is by testing it upon the ore to be crushed, and this process requires some unit for expressing the character of the ore itself. In other words, a unit factor must be found that will explain the character of the rock; then the work done upon it by different machines can be intelligently compared. Consequently it will be possible to select the best machine to do the required work. Unfortunately, the basis for comparison has not yet been agreed upon.

Those interested in the subject are aware of the discussion, which has been occupying a prominent place in the technical press for the last three or four years, regarding the accuracy of the laws of Rittinger and Kick, one of which has been advocated by Stadler and the other by Gates. The discussion is still on. A universal standard, mathematically true, is the logical beginning, so it must be first decided which of these laws is the correct one to apply and which system of units to use. Stadler's energy-unit is advantageous if it be proved that Kick's law is true. Gates' unit, using the crushing-surface diagram, is also easily applicable and readily useful if it can be proved that the basis of his argument, which rests on Rittinger's law, is correct. In a general review of the situation, then, it may be said that while we welcome every step, no matter how small, toward standardizing test reports, the field of rock-crushing comparisons will never be complete until a permanent foundation has been laid.

The many current reports of steel consolidations carry one back to the days of the formation of the Steel Corporation and other well-known combinations. As nearly as can be stated with any approach to precision, three strong financial groups are in the field. The most prominent of these is the Schwab, or Bethlehem Steel, party, which is believed to have the backing of the Carnegie interests; the second is the Corey-Midvale group, understood to be supported by Standard Oil interests; and the third is the Downer-Frick party, which now controls the Cambria Steel Co., and is contending with Bethlehem for the ownership of the Pennsylvania Steel Co. The outcome is still far from certain.

The discussion of the first report of the Committee of Standardization of the Mining and Metallurgical Society of America, by the members of the New York section, as reported in the September bulletin of the society, brought out some excellent ideas. The discussions that take place at the meetings of this society are always frank and illuminating and show the benefit to professional men of meetings where such discussions may be developed. The monthly bulletin of the Mining and Metallurgical Society is a relatively small publication, but it is one of the most useful issues of our technical literature.

An increased use of shoveling machines and greater activity in their invention and perfection may be looked for as a result of the present involuntary restriction of immigration. In good times one of the classes of mine labor hardest to get is muckers. We may look to see an aggravated scarcity in the near future.

BY THE WAY

A summer-school mining student was assigned to investigate the details of breast mining at the colliery visited by his class. Recalling an engagement with a demure maiden of Hazleton, he made a short day of it; but, to his consternation, upon emerging from the shaft he encountered the instructor in charge. Without waiting for an accusation, he hastily exclaimed, "Why, Professor Bell, I learned everything there was to know and I'm on my way to work up my notes." "Ah, Mr. Morris," was the reply, "just this morning I met an old fellow who has been mining for twenty-five years, and he tells me that he learns something new every day. But you have mastered it all in a few hours. I congratulate you."

⁂

Must we furnish a wire-gauze jacket for the mule-barn cat or shall we ground him? asks the *Colliery Engineer*. In other words, must we furnish "permissible cats as well as permissible explosives"? An accident reported from New York City seems to suggest an unsuspected danger lurking in the cat's fur. According to the newspapers there was an explosion in a gas chamber used by the Society for Prevention of Cruelty to Animals to asphyxiate stray cats and dogs, ordinary illuminating gas being used. The formation of an explosive mixture in the chamber could easily be accounted for, but what fired it? Someone who had seen pussy's fur snap when stroked suggested that the cause was an electric spark caused by the rubbing together of the frightened cats. Thus another indictment is laid against our childhood's friend.

⁂

The new British budget, which provides for a supertax of 50% on the profits of all British companies, has already caused the removal to the United States of the headquarters of several companies representing South and Central American gold mines, says a London dispatch to the *Times*. Mining men assert that unless the tax be reduced, this movement will become so great that New York, instead of London, will become the mining capital of the world. Mines whose production is just beginning are particularly hard hit. Unlike tea and rubber companies, mining companies have not been enabled by the war to raise their prices. The excess of profits is determined under the new ruling by subtracting from the income for the current year the average income for any two of the last preceding three years. Mining companies just coming into the field have no such opportunity, and will be compelled to pay 50% of their total profits for the year. The tendency to remove headquarters to the United States is becoming so pronounced that mining interests in London are bringing pressure to bear on Chancellor of the Exchequer Reginald McKenna to have the supertax modified in favor of gold mines. A correspondent to the *Financial Times* points out that Rand gold-mining companies are already heavily taxed. In the first place, a profits tax is payable by the mining companies to the government of the Union of South Africa, and, secondly, a special war tax has been levied on the mines as a contribution toward the recent campaign. In addition, the shareholders resident in the United Kingdom have to bear the income tax (which is deducted in the ordinary way as unearned income from the dividends); as this rate will now be subject to a further increase, surely the shareholders are already bearing more than their legitimate share of the burden.

⁂

October Mining Dividends

Dividends disbursed in October, 1915, by 31 United States mining companies making public reports amount to $5,911,591, as compared with $3,551,160 in October, 1914. Industrial and holding companies allied to mining paid $3,315,458, as compared with $2,479,629 a year ago. Canadian and Mexican companies paid $1,359,588, as compared with $1,078,241 in October, 1914.

The totals for the first 10 months of the year are as follows: Mining companies, $57,311,674, as against $49,242,100 in 1914; metallurgical and holding companies, $65,441,802, as against $50,127,102 in 1914; Canadian and Mexican mines, $7,441,708, as against $13,680,365.

The drop in metallurgical and holding companies' disbursements is less, considerably, than the difference made by the passing of the dividends on United States Steel common. The returns from Mexican and Canadian companies for the first time this year show an improvement over the corresponding month of last year. As to the position of this country we are not yet in position to throw up our hats and shout with disturbing loudness, for in 1913 United States mining companies paid $62,175,610 in the first ten months of the year.

PERSONALS

J. Ernest Snelus left London recently for Nigeria.

R. S. Innes, of London, has gone to the Belgian Congo.

Frank Rowley has left London on his way to Tasmania

R. V. Barton has gone from New South Wales to Chosen.

W. R. Feldtman is in West Africa on professional business.

J. Kobuse has been examining mining property in Chosen.

A. G. Wolf, of Denver, is in Gunnison County, Colo., on professional business.

H. C. Hoover, who is doing such wonderful work for the Belgians, is spending a week in New York.

William Thomas left London recently on his way to the Champion Reef Mine in the Kolar District, Mysore, India.

Frank Reed, inspecting engineer of mines in New Zealand, has been appointed also chief inspector of coal mines.

Charles Botsford, of New York, has placed two Kirkwood exploration propositions with Michigan Copper Country people.

W. H. Wright, of the Malm-Wolf Co., has completed the examination of placer properties near Alma, Colo., and has returned to Denver.

L. F. S. Holland has returned to Los Angeles, Calif., after making examinations in Pioche, and Cherry Creek, Nev., and in San Bernardino County, Calif.

Lieut. J. Cameron, mining engineer of Toronto, who enlisted for service abroad in the first Canadian contingent, was wounded in a recent engagement.

C. W. Whitley, manager of the American Smelting and Refining Co., in Utah, and W. H. Howard, metallurgist for the company in the West, are visiting New York.

John Daniell, mining engineer of Laurium, Mich., is home from the new Kirkwood district in Canada, having secured a property which will be financed by Laurium people.

James J. Ormsbee, formerly superintendent of the El Paso smeltery, and more recently of the Tacoma and Hayden plants, is spending a couple of weeks in New York, with headquarters at the A. S. & R. Co.'s offices.

H. J. Rahilly has returned from the Matanuska coal field in Alaska, where he spent six months on professional business for the General Land Office. He has accepted a position with the Bureau of Mines and is now stationed at Pittsburgh

L. Selmi, chief chemist-metallurgist of the Otis Steel Co., Cleveland, has resigned, effective Nov. 1, when he will take charge of the chemical and physical laboratories of the new steel plant of Corrigan, McKinney & Co., Cleveland, Ohio.

Angus W. Smith, largely interested in the White Pine Extension in Ontonagon County, Mich., is in the district with Frank McM. Stanton of New York, superintending the construction of the shafts and continuance of diamond drilling.

R. B. Bostwick, superintendent of the openhearth steel department No. 3 of the Homestead works of the Carnegie Steel Co., has resigned to become associated with the Upson Nut Co., Cleveland T. J. Jamison has succeeded Mr. Bostwick at Homestead

OBITUARY

Charles Smith died recently at Hubbell, Mich. He was chief clerk of the Calumet & Hecla smelting plant at Hubbell, and one of the oldest employees of that corporation. He was employed at the smelter from the day it started. He served many years in the legislature and on the county board of supervisors. He was prominent in Masonic circles.

Howard E. Burton, well-known assayer, metallurgist and operator of Leadville, Colo., died Oct. 16 at Glenwood Springs, of typhoid-pneumonia after a very brief illness His death was a shock to his host of friends, for he was a man in the prime of life and in good health He was born at Lake Geneva, Wis., in 1870 He graduated from the University of Wisconsin in 1893. In 1895 he located in Leadville as chemist of the Elgin smeltery and he has lived there continuously since that date. Upon the closing down of the smeltery he opened a custom assay office that he maintained to the time of his death. He was known by his liberal advertising that resulted in a large mail-order assay and analytical business. He was largely interested in many of Leadville's important discoveries and projects. Recently he has been exploiting molybdenum deposits a few miles north of Leadville. He was one of the owners of the new smeltery at Leadville erected for custom treatment of the non-sulphide zinc ores of the district. During the early years of cyanidation he erected a leaching plant at the Penn mine north of the city and attempted to treat the enormous mine dumps without crushing, but his efforts were only partially successful. In a similar way he has ever been foremost in inaugurating projects for furthering the interests of the Leadville region. He was a member of the Masons, Elks, Phi Delta Theta, Woodmen of the World and the Royal Arcanum. His funeral was held Oct. 19 under the auspices of the Masonic fraternity, at Leadville.

SOCIETIES

New Mexico School of Mines is building new metallurgical building and other edifices at Socorro, N. M. Power plant with 50-kw. generator and two oil engines to be installed.

American Society of Mechanical Engineers—A meeting of the New York Section will be held at the Engineering Building, Nov. 9. Charles Meigs Ripley, will present the paper of the evening, which covers an investigation of the size, age and performance of gas-producer power plants in New York City and neighborhood. The paper reports the results of a census showing the owners' opinions regarding repairs, labor and depreciation; satisfaction and dissatisfaction which they have experienced with their plants; and future policies.

American Institute of Mining Engineers—The Columbia Section will hold its annual meeting at Wallace, Idaho, Nov. 19 and 20. The first day and evening will be devoted to technical papers and discussion, and the second day will be given over to sightseeing, probably a visit to the great Interstate-Callahan zinc mine. The program will include a paper on "Progress in Ore Dressing" by D. W. Buckby, superintendent of the Stewart mill. "Zinc Smelting and Smelting Rates" is the subject of a paper that will be presented by W. L. Henry, of the Empire Zinc Co., of Denver. J. E. Chapman, chief accountant of the Federal Mining and Smelting Co., will read a paper on "Mine Accounting." The Columbia section includes Idaho, Eastern Washington, Eastern Oregon and part of British Columbia and has 104 members. Members of the Montana section have been invited to attend.

INDUSTRIAL NEWS

The Carbo Steel Post Co. of Chicago has changed its name to the Carbo Corporation. No change in the personnel of the organization has been made.

Industrial Works has established a Philadelphia office in the Widener Building. Complete data and information can be obtained there regarding the Industrial Works line of locomotive, wrecking and freight-handling cranes, pile drivers, grab buckets, etc.

On Oct. 1 the property and business of E. I. du Pont de Nemours Powder Co., of New Jersey, was sold and transferred to E. I. du Pont de Nemours & Co., of Delaware, a corporation organized for the purpose of taking over and carrying on the business. The new company assumes all liabilities of the old company (except capital stock and funded debt) and will carry out all contracts of the old company, there being no change in the personnel of the management, operations or methods of handling the business. It will issue capital stock to the amount of $120,000,000. E. I. du Pont de Nemours & Co. the new corporation, bears the name of the original Delaware concern established 1802 by E. I. du Pont de Nemours. The return to the original name is a tribute to the founder and emphasizes the long establishment of the business. The incorporation was made in Delaware because Delaware was where the business originated and the main offices are located in Wilmington. Although the du Pont facilities for manufacturing and selling explosives have materially increased, explosives are no longer the only products of the organization. The chemical business has entered many industrial lines and further extensions are inevitable. Du Pont Fabrikoid Co. a controlled concern is making exceptional progress, and enlargement of its productive capacity has been and probably will be continuous as a result of steadily increasing sales.

Editorial Correspondence

SAN FRANCISCO—Oct. 28

Protection of Investors in mining properties is apparently one of the purposes of the State Corporation Commission which is operated under the blue-sky law. Recently a permit was issued to the Forest Hill Mining Co. to issue 50,000 shares of stock in payment for 2 placer claims and to issue 300 shares for services, upon condition that the shares are accepted at a valuation not less than 25c. per share, the price at which the company is permitted to sell an additional 30,000 shares for development purposes. The commission for selling is limited to 20%, and the 50,000 shares payment for property must be deposited in escrow, pending the financing of the company. In issuing stock to the original incorporators they must enter into separate agreements with the company that they are not receiving their shares as fully paid, but on the same basis as other purchasers. Meantime a mine promoter of San Francisco was arrested at Liveoak on complaint of ranchers in the vicinity that he had collected from them several hundred dollars with which he was to secure rich mining claims in Siskiyou County. The promoter excused himself on the ground that before he had an opportunity to secure the mining property, he was held up and robbed. He may go to prison for obtaining money under false pretence, but the farmers of Liveoak will not get their money back, and are just as apt to bite at another sucker proposition in spite of the blue-sky law, which, of course, has nothing to do with this class of criminal promoters.

DENVER—Oct. 28

Cripple Creek Deep Drainage and Tunnel Company's Executive Committee met, Oct. 12, at Colorado Springs, and decided, among other matters, that, upon the completion of the bore on its present course to the Elkton shaft, its direction be thereafter carried on a line nearly due east to the Golden Cycle shaft a further distance of approximately 8,000 ft. The Elkton shaft should be reached about Jan. 1. Irving Howbert resigned from this committee and was succeeded by Frank G. Peck, another officer of the Portland company. Great credit was given Charles M. Fuller, superintendent of the tunnel, for his excellent work and he has been sent to the Michigan iron regions to investigate mechanical muckers there in use and to decide upon their adaptability in his Roosevelt tunnel work.

Washing and Concentration of Hillside Débris has been undertaken by a new concern known as the Omaha Concentration and Mining Co. At two localities in the Cripple Creek district, this company has installed equipment of its own devising to cull gold from the soil, sand and gravel covering the slopes of the mountains—in the Kitty Hollis claim near Windy Point and in the Isabella territory on Bull Hill. At the former plant, treatment consists of following simple steps. With ordinary horse plows and scrapers the dirt is loosened and delivered to a bin whence it travels by conveyor belt to a stationary half-inch screen that rejects coarse gravel, roots and other worthless material. This half-inch product passes to a trommel with 5-mesh screen through which the finer material is washed by water, the undersize being immediately given its final sizing through a 10-mesh trommel. A spectator judges, from this arrangement, that the proprietors do not expect any coarse gold particles in this "wash." The small quantity of fines finally retained below the screens goes to a Harrington table, a machine for which originality is claimed. This table is a modified gold sluice, with an oscillating, longitudinal motion. Its bed contains semi-round grooves 2 in. deep by 2 in. wide running crosswise, acting as riffles. In these grooves rods of iron with fingers are caused to slide back and forth keeping the sand in motion. Clean-ups are made intermittently by sweeping the concentrate from the grooves. At the Isabella plant, not yet in operation, the first screened product will pass through rolls to release particles of gold in the quartz fragments as it is proposed to treat here both wash and dump material.

SALT LAKE CITY—Oct. 29

A Miners' Strike, involving 370 men was inaugurated at the Silver King Coalition mine, Park City, Utah, following a proposal by the company of a compensation plan, which does not meet with the favor of the men. This is the first strike in the history of the company which has been operating 30 years. According to the plan, the Silver King Coalition Provident & Insurance Association is to be formed, each miner paying $1 a month to the association, and the company a like amount—the funds of the association to be subject to the direction of six trustees, three to be chosen by the miners, and three by the management; in cases of disagreement the general manager of the company to act as arbiter and cast the deciding vote. In case of the death of an employee occurring on the property it is proposed to pay not less than $2,000 to the heirs, this sum being liable to increase at the discretion of the board of trustees; for permanent total disability the payment of not less than $2,000 is proposed, and for partial permanent disability not less than $1,250; and in cases of temporary disability not less than $12 a week, unless the board of trustees shall otherwise direct. The miners also object to the proposal made by the company that all cases be taken to the Holy Cross hospital at Salt Lake for treatment. Up to the present time the men have been paying $1 a month to the miners hospital at Park City. The larger number of the employees went on strike the morning of Oct. 26, leaving engineers and pump men in their places until 6 p.m., Oct. 28, and demanded that they be given the privilege of assigning their $1 to any hospital and the abolition of the company's insurance plant. At 6 o'clock, receiving no reply from the company the engineers and pump men joined the strikers after the mules in the underground workings had been brought out by the miners, and at present the water is coming into the workings at the rate of 600 gal. a minute. Thomas Kearns, general manager of the company, who was away at the beginning of the trouble, has arrived in Salt Lake City, and is awaiting overtures from the miners. If the water rises to the 1,300 level, the new electrical equipment (described on page 747 of this issue) may be seriously injured, it is stated, entailing a considerable loss. About two-thirds of the miners are non-union men, and the greater number are Americans. The Western Federation of Miners has espoused the cause of the Coalition miners, and pledged its support. The men have been warned to act in an orderly manner, and so far there has been no disturbance.

SEATTLE—Oct. 28

Navigation in the Arctic Ocean has closed for the season, according to a dispatch from Nome.

Deals in Broad Pass Mines are falling through because of an apparent intention of the owners to make unreasonable demands of those with capital who are anxious to prospect the ground thoroughly with a view of purchasing. Representatives of capitalists have looked the ground over, but have been unable to make any arrangements with the present owners and it seems likely that little real development work will be done in the district at present.

Larger Output Is Certain in the Fairbanks District, according to the latest figures. Every month this year to date, the output has been larger than the corresponding months of last year and indications are that the same conditions will continue during the remainder of the fall. Last year the opencut operators were hurt considerably by heavy frosts and the cold nights during the early part of September and October, and it is not likely that conditions will be any worse this year. All opencut plants have done well this summer, having had plenty of rain for the greater part of the time and having got an early start in the spring. The dredge on Fairbanks Creek started late but is doing well and will continue to work right up to Nov. 1 if possible. Hiltys plant, on Cleary Creek, is working full time and has increased the output considerably. The Pedro Creek operators are taking out more money than last year. Ester Creek is producing more gold than in 1914. Cleary and Chatanika are fully as good as last year and some of the operators are taking out a great deal more dust than in 1914. Several thousand dollars of gold has come down from the Tolovana district but the district will not show up to its true worth until 1916 and everyone in the Fairbanks district believes that with the increased production of the Tolovana added to the increased production of the Fairbanks district will show the entire territory in the vicinity of Fairbanks a larger producer in 1916 than since 1911.

MORENCI, ARIZ.—Oct. 29

The Clifton-Morenci Strikers' Delegates and the mine managers concluded their deliberations Saturday, Oct. 23, without reaching agreement on a single point. The managers again restated the only conditions under which they will resume work: The federationists must get out and the men must return to work under the pre-walkout conditions. When these requirements are met and normal conditions are restored, the managers will meet the employees, as they have always heretofore been willing to do, and discuss any grievances the employees wish to take up. In order that the public might have a clear conception of the situation, the officials gave out a brief industrial history of the district and a resumé of the incidents leading up to the strike. Owing to the orebodies being small and scattered over a wide area, the district could never have been opened up in the early '80s but for the abundance of cheap Mexican labor. The constantly lowering of the grade of ore, the very small tonnage per man as compared to that in other places in the state (about 3 here to 8 elsewhere), make it impossible for the companies to pay the same wages as are paid at other camps, which the strikers demand. The sliding scale adopted with the improvement of market conditions early this year, although it gave the employees more money at corresponding copper prices than they had received prior to the 10% cut when the slump came one year ago last August, did not give the 10% back in a lump sum. Thus the field was particularly attractive to the federation organizers. Governor Hunt and Attorney-General Jones, told their brethren at the beginning that the strikers' cause was "the cause of Almighty God" and that if the managers didn't "quidado" they might find themselves in "the bull pen." The governor has sent another detachment of troops to the district to guard against the entrance of a few thousand imaginary strikebreakers being assembled at Duncan. Or perhaps he wants to pour oil on the waters on account of petitions being circulated throughout the state for his recall. Young J. Pentland and Willis E. Miller, of Edinburgh, Scotland, members of the Arizona company, who are now in El Paso, have not accepted the invitation tendered by the federation to come to Clifton and "learn just how bad and inefficient their executives are."

CLIFTON, ARIZ.—Oct. 30

Strikers in Clifton-Morenci District have assumed an attitude of "watchful waiting" with the definite understanding that a federal investigation of causes leading up to the strike and of conditions existing at present will be held soon by Commissioner Myers, under direction of Secretary Wilson of Department of Labor and Commerce. The union reports finances plentiful and more in sight. There is no indication that the strikers' committee is contemplating presenting a new proposition to mine managers.

HOUGHTON, MICH.—Oct. 30

Taxation of Mines is likely to become a prominent issue in the Lake Superior district next month. At the last meeting of the board of equalization of Houghton County, the assessed valuation of Adams, which includes the three mines of the Copper Range Consolidated and is represented on the county board of supervisors by F. W. Denton, the manager of the mines, was raised more than $2,000,000 above the figures of Mr. Denton. He immediately protested when the report was made to the county board of supervisors. Supervisor Seeber, representing the St. Mary's Mineral Land Co., also protested, claiming that if the additional figures were spread on the Adams township taxes they would have to be paid, in large measure, by St. Mary's company, as they would not be put back on the mines. The state board of tax commissioners set aside a date for hearing and review of Adams township mineral land and mining assessment. Supervisor Denton claimed that the assessment of $16,000,000 on Adams township was too high and that the assessments of $29,000,000 on Calumet mines and $6,000,000 on Osceola mines were too low. He also complained that the method of reaching taxation valuations was unreasonable.

ISHPEMING, MICH.—Oct. 9

The Outlook on the Michigan Iron Ranges is excellent. It has been a good many years since the operators have started opening mines on the Michigan iron ranges when the end of navigation for the season was in sight. However, such is the condition right now, and it looks as though the coming winter would witness considerable activity. Shipments are continuing at a steady rate, and more ore would be going forward if the railroads could supply the cars. The Chicago & Northwestern Ry. placed an order last week for 500 new steel cars, and the Lake Superior & Ishpeming road ordered 400 steel cars last spring that have not been delivered yet. The operators feel certain that they are going to receive an advance of 50c. a ton for their product next year, and several of the companies have already announced that they will not close any more contracts at the present selling prices. The Cleveland-Cliffs Iron Co. and Corrigan, McKinney & Co. have withdrawn from the market, although both concerns have ore in stock that they might sell and ship this season. The latter company resumed operations at the Tobin mine, in the Crystal Falls district, this week, placing a large number of men at work underground. This is one of the big mines of the Menominee range and employs between 400 and 500 hands when working to capacity. It was closed over two years. This same company has taken a lease on the Cole & McDonald property, near Crystal Falls, and will start development work shortly. Cole & McDonald secured possession of the tract and drilled it thoroughly, proving up a large deposit of ore of good grade. The Fortune Lake Mining Co., a subsidiary of Oglebay, Norton & Co., will sink two shafts on the property recently drilled near Fortune Lake, in the Crystal Falls district. It was only a few weeks ago that a contract was awarded to change the course of Briar Hill Creek, which flows over the orebody, and which would make mining difficult. The Cleveland-Cliffs Iron Co. has added 60 men to its force at the Cliffs shaft mine, at Ishpeming. The production of this property is to be increased several hundred tons a day by doing part of the tramming and hoisting at night. The Volunteer Ore Co. has resumed operations at its mine at Palmer, which has been idle over a year. The outlook is certainly encouraging in the Michigan field.

TORONTO—Oct. 26

A Hydro-Electric Plant to supply power to the new gold district of Boston Creek, a short distance from Swastika, is to be financed by a local syndicate. If there is any surplus of power it will probably find a market at Kirkland Lake.

Many Wide Dikes Have Been Uncovered in the Kowkash gold area. A number of prominent Porcupine mining men have been prospecting in the district. An important find of Tellurides about 35 mi. west of Kowkash is reported. A direct Pullman car service from Toronto to Kowkash is in operation.

The Zinc Deposits at Burbridge, about 72 mi. from Ottawa, in the Gatineau region, have been investigated by J. D. Macfarlane, who has returned with samples of ore and confirms reports as to the richness of the deposit. He states that every 750 tons of ore mined will yield 100 tons of zinc, and that in one spot 40x25 ft. in area there is 40% zinc. The outcrop, which is 2½ mi. from Burbridge station, is of highly crystalline limestone at the base of a limestone ridge. The deposits were found some years ago, but as the locality was difficult of access, and zinc not so much in demand as now, the claims were simply staked and no effort made to develop them.

VICTORIA, B. C.—Oct. 26

Two Finds of Copper have been made recently that promise to be of more than usual interest. One is on Owl Creek in the Lillooet, where chalcopyrite and native copper occur in a silicious schist. The body appears to be of considerable extent and samplings made by J. A. Beaudette for Foley, Welch & Stewart show about 5% copper. The other discovery is near Jones Lake in the Hope district. It was covered by a glacier, but the extremely long warm season melted the ice and exposed it. The vein has a width of from 28 to 50 ft. and has unusually high mineral content.

CALCUTTA—Sept. 8

New Indian System of Weights—The Indian Government in October, 1913, appointed a committee to consider the question of uniform weights and measures within the Indian Empire. The recently published report of this committee is of considerable importance, affecting as it does, the commercial transactions of one-fifth of the world's population. The adoption of the metric system and alternatively of the British, was considered and rejected. The former, principally upon the ground that the use of decimals was alien to the customs of the Indian people. The latter, because it would have compelled an alteration in the weight of the tola, the most important standard of weight in use. Moreover, the weight of the tola and of the rupee being identical, the weight of the coin would also have had to be altered. The committee recommended that the Bengal, or Indian railway, weights should be adopted for universal use throughout the Indian Empire, with the exception of Burma, where a uniform system suitable for that province already obtains. The proposed weights are as follows, for India: Eight khaskhas make 1 chawal; 8 chawals, 1 ratti; 8 rattis, 1 masha; 12 mashas or 4 tanks, 1 tola; 5 tolas, 1 chatak; 16 chataks, 1 seer; 40 seers, 1 maund. A tola, the weight most used with reference to silver, is equal to 180 grains troy.

The Mining News

ALASKA

INDEPENDENCE (Seward)—Two hundred ounces of gold in five days with only 10 men and a miserably small plant is record of this property on Willow Creek. L. S. Robe is superintendent.

NEVADA CREEK (Douglas Island)—Mike Hudson, of Douglas is in charge of gang of 20 men that has started work at Nevada Creek mine which was recently sold after much financial distress following its operation by English capital. Development will be pushed rapidly.

ALASKA COPPER CORPORATION (Strelna)—Consulting Engineer Du Bois has finished his work for the year and has left for East. Compressors and drills will be installed in near future. Property is situated off Copper River & Northwestern Ry., in Copper River Valley about 25 mi. from famous Kennecott locations.

CACHE CREEK DISTRICT (Seward)—J. H. Rice, an operator on Willow Creek, in Cache Creek district, has just arrived in Seward from his placer claims. Owing to shortage of water he was able to work only about 45 days, but took out, in this time, $4,000 in dust. He describes property as having three distinct paystreaks of varying width and richness. Richer gravel on bedrock occasionally ran as high as $7 to the pan. Dust is high-grade, running nearly $18 per oz. after melting. Mr. Rice will shortly make the return trip of about 300 mi. with intention of remaining upon claims through winter.

CALIFORNIA

Amador County

ERNEST (Jackson)—Reported good body of ore disclosed at this mine near Doyle place.

BOITANO (Jackson)—Property reported to have been bonded; definite information not available. Situation adjoining Hardenberg makes it attractive, though Hardenberg is still idle.

FELLOWCRAFT (San Andreas)—Mine has been unwatered and well mineralized ledge exposed on 200 level. Thorough test of both 200 and 100 levels will be made before development is begun.

Butte County

BUTTE COUNTY R.R. reported to have been negotiated for by Southern Pacific and that latter company will extend line from Stirling to Westwood in Lassen County to connect with Fernley & Lassen branch. Butte County R.R. is operated by Diamond Match Co., between Chico and Stirling, under lease which will soon expire. Extended line will place Chico on transcontinental line and open up new mining regions.

Colusa County

MANZANITA (Williams)—This quicksilver mine at Sulphur Creek leased to H. B. Bradford, of San Jose. Reported that rich pockets of ore have been disclosed. Mine closed down two or three years ago by men who purchased of George V. Northey, who introduced concentration into metallurgy of cinnabar. Northey made successful concentration by use of Gilpin County bumpers and canvas tables. Though method was crude, attention of quicksilver miners was attracted to economic feature of practice. Some improved methods have been experimented with but most of larger operators still continue old process of direct roasting of coarse ores and retorting fines.

Eldorado County

CHEROKEE FLAT (Georgetown)—Davis and Federwitz, of Placerville, are developing this property on middle fork of American River, situated on Mother Lode. Vein is large and of good milling value and will be tapped by crosscut tunnel at depth of 100 ft.

STEAM-SHOVEL and locomotive equipment is being installed on Webber Creek, 6 mi. from Placerville, for operation of gravel mines. Gravel dug by steam shovel will be dumped into 4-cu.yd. side-dump cars and hauled by locomotive to sluices. This is first time that combination of steam shovel and locomotive has been adapted to gravel mining in California. George W. Kirkley is manager.

NEWTOWN RIDGE gravel mines at the head of Missouri Cañon will be opened by a 500-ft. crosscut tunnel to be driven at depth 200 ft. below old river channels believed to contain cemented gold-bearing gravel in quantity to make undertaking profitable. At intersection of tunnel and channel raises will be driven. L. A. Bender and Charles Wright have taken bond on 160 acres of land for this purpose.

Kern County

OLD MILLS ANTIMONY MINES are being operated in a small way. Carload of ore is reported ready for shipment. Property is situated in Devils Cañon about 7 mi. from Caliente.

CALIENTE CAÑON mines owned by J. B. Ferris, of Bakersfield, reported sold to Western mining men at large figure. Said to be large amount of low-grade ore disclosed by small amount of development.

Nevada County

HIGH-GRADING at Empire mine resulted in sentence of Andrew H. Coggins to 4 years in state prison. Coggins pleaded guilty in Superior Court. Archibald Boone, an accessory, escaped punishment, as ore had been recovered. Coggins had stolen about $50,000 worth of high-grade and specimen ore; but he had not disposed of any of it to his own profit. Boone assisted him in removing stolen ore from Nevada City to San José; but neither of them profited by the theft.

ENGLISH MOUNTAIN (Nevada City)—High-grade ore reported by Henry C. Schroeder who is operating under lease.

NORTH STAR (Grass Valley)—New hoist installed complete and in operation. Ore is being dumped into steel bins which are part of this new equipment at Central shaft.

Tulare County

TULARE COUNTY POWER CO. (Tulare)—Property sold to Mount Whitney Power & Electric Co., and corporation dissolved by court.

Tuolumne County

FLOODING OF MINING CLAIMS by Goodwin dam will be taken into court in suit for $10,000 damages by H. A. Preston, postmaster of Jamestown, against Oakdale and San Joaquin irrigation districts.

COLORADO

Boulder County

BOULDER TUNGSTEN PRODUCTION CO. (Nederland)—Has let contract to Colorado Iron Works, Denver, for erection, within 90 days, of complete concentration mill to have crushing capacity of 60 tons, and concentrating capacity of 35 tons per day. Flowsheet is as follows: Bins; conveyor belt to grizzly; Blake crusher; belt conveyor to 27x14 rolls crushing to $\frac{3}{4}$ in.; 20x5½ rolls crushing to 12 mesh; elevator to impact screens; jigs; classifiers; Wilfleys; Deisters; tails and oversize from screens elevated to 3x4 ball mill; cone thickeners; slime tables.

Clear Creek County

PRIMOS CHEMICAL CO. (Empire)—On Oct. 16, closed down operations in molybdenite mine in Daily district until cloud on title to property has been cleared by litigation now being waged between original owners who sold to this company years ago.

SANTIAGO (Georgetown)—Recent development operations in this mine in East Argentine district have opened vein of ore 2 to 4 ft. wide which ranges in value from $20 to $45 a ton in gold, silver and lead. During the past month about $4,000 worth of ore has been produced from development. The product is hauled in wagons to Georgetown whence it is shipped to smeltery at Salida. Systematic development is being pushed under direction of Frank Ricci.

Dolores County

EMMA (Rico)—Arrangements are being made to install flotation apparatus in the mill to handle complex sulphides.

RICO-WELLINGTON (Rico)—This and Rico-Consolidated, both owned by Knight Investment Co. of Salt Lake City, shipped 62 carloads during September.

Eagle County

TWILIGHT (Fulford)—John Weiskopf and John Storey have emerged from their mysterious camp in mountains south of here, bringing wonderful specimens of free-gold ore. They declare they cannot do further prospecting until spring, since their discoveries are very high. There promises to be a stir among prospectors in this region next spring.

Lake County

GRANITE TUNNEL (Granite)—Julius Hoffman, stockholder and creditor in this defunct company, has purchased all its properties at sheriff sale.

GARBUTT (Leadville)—Large double-drum hoist has been installed. Hereafter hoisting will be done in both compartments of shaft. Ore reserves are said to be very large. Building of proposed mill has been postponed until next spring owing to climatic conditions.

Ouray County

NATIONAL BELL (Ouray)—Davey Leasing Co. shipped 2 carloads to Durango smeltery, part of the material coming from mine dump.

WANAKAH (Ouray)—Large body of 5% copper ore carrying small amounts of gold and silver, making average grade of material about $15 per ton, found in old workings. Stuff was not marketable during former operations, but is excellent for company's smeltery now.

Pitkin County

CHARLES HARRIS AND KEMPER DUNLAP, prospectors, claim to have made important finds of ores carrying tin, antimony, copper, lead and zinc in the country about the heads of Avalanche, Capitol and Snowmass creeks in the Elk Mts., about 12 mi. west of Aspen.

San Juan County

SILVER LEDGE (Chattanooga)—Leaser Bonavida is mining and milling a fine grade of galena-sphalerite carrying gold and silver. Mill makes two clean products.

ALL O. K. (Silverton)—This property in Minnie Gulch is being reopened and developed by James O'Kelly. Main crosscut tunnel is being advanced toward Kittimac property. Recent metallurgical tests on All O. K. ore indicate that it can be treated satisfactorily by cyanide process

COLUMBUS (Animas Forks)—Manager Arthur Johnson estimates that tunnel will reach Columbus oreshoot during early part of January. Drifts will be driven both ways on vein. Shipments of ore are being made from upper workings and will continue as long as railroad is open.

GOLD KING (Gladstone)—Has been decided to convert entire plant to flotation process. Production of ore will necessarily cease during changes in mill, but underground development will proceed in anticipation of greater mill demands. Plans contemplate largest flotation mill in state.

TOMBOY (Telluride)—During September, mill treated 13,000 tons, recovering $45,000 in bullion and $40,500 in concentrate. Monthly expenses were $56,700. Despite low average value of this ore (=$6.58 per ton) the cost of $4.36 per ton is low for the conditions prevailing in this rugged region.

Teller County

CRESSON (Cripple Creek)—Mining and hoisting suspended few days last week while repairs were made in shaft.

GOLD DOLLAR (Cripple Creek)—Dell Brothers, leasing 500 level, shipped 30 tons from new shoot, receiving returns at rate of 2.21 oz. gold per ton.

GOLD SOVEREIGN (Victor)—Stockholders have voted to extend life of incorporation for another 20-year period. Mine is leased to Gold Sovereign Mining and Tunnel Co.

VINDICATOR CONSOLIDATED (Independence) — Net earnings from operations for third quarter of 1915 were little over $225,000, out of which five additional notes, of series issued in purchase of Golden Cycle mine, were paid, making 19 in all, together with six months' interest on balance of series remaining unpaid. This was accomplished with but small reduction in cash balances from those of previous quarters. Developments on 18th level of Golden Cycle disclose two different oreshoots in main veins amounting together to ovef double length and volume of orebody on 17th level, but of lower average grade. Further development on 17th and 16th levels has opened additional ore. About four-fifths of shaft sinking for two additional levels has been accomplished, including cutting of station for 19th level.

IDAHO

Shoshone County

GOLDEN WINNIE (Murray)—Erastus Smith, owner of this tungsten property, has given 30-day option to Bennett Bates on basis of about $50,000. Has small mill run by water power. Several small shipments have recently been made.

REINDEER-QUEEN (Mullan)—E. B. Crawford has been elected president. Car of high-grade copper ore will be shipped soon. Driving on vein is under way and tunnel has just entered Queen ground for first time; face of drift shows 4 ft. of shipping ore, according to reports.

MINNESOTA (Wallace)—Under management of O. B. Wallace, who organized Interstate and managed it until its consolidation with Callahan, Minnesota Mining Co. is developing group of claims adjoining California, on Nine Mile, about 2½ mi. from Wallace.

GERTIE (Wallace)—Long Gertie crosscut adit has been driven 3,720 ft. in 12 months, average of 311 ft. per month under system whereby miners receive bonus of $25 to $40 per month. Adit is 6 by 8-ft. section and has cost $67,000, which includes cost of machinery and other equipment.

MARK COONEY (Burke)—M. W. Neary, of Spokane, has made payment of $25,000 on option on Mark Cooney group, near Burke. Second payment of $75,000 is due in one year and final payment of $75,000 six months later. Property consists of 4 claims, patented in 1901 and idle since.

AMERICAN-COMMANDER (Mullan)—Preliminary work was started on American-Commander this week, preparatory to extending lower tunnel to vein. Will secure power from Independence Lead Mines Co. American-Commander is supposed to be on Hunter vein and good ore showing is reported in upper tunnel.

CONSTITUTION (Pine Creek)—Ex-Senator George Turner and Frank G. Graves, of Spokane, have taken option on large block of stock of Constitution M. and M. Co. Mine has shipped 3 cars of crude zinc ore, which has been penalized by smelters on account of 10% lead content. Compressor and hoist will be installed at once and if developments justify mill of 150 tons capacity will be built.

MONITOR (Adair)—Has recently started 6,000-ft. tunnel near railroad at Adair which will explore its ground at depth of 1,100 ft. Tunnel is designed to form outlet for adjoining properties also. Tunnel is now in 500 ft. New boarding and bunkhouse just completed to accommodate 16 men, also new compressor building. Old workings on Idaho-Montana divide consist of shaft 700 ft. deep, from which copper ore amounting to $70,000 has been shipped to Saltese, Mont. Buildings at upper works burned in forest fire several years ago. Ore returned 20% copper and considerable gold.

MICHIGAN

Copper

MOHAWK (Kearsarge)—Copper content risen remarkably in six months, now showing 21 lb per ton

WHITE PINE (Ontonagon)—Railway connection, by way of St. Paul and Calumet & Hecla spur will be completed.

TAMARACK (Calumet)—Lake Superior shareholders are convinced that there will be no consolidation with Calumet & Hecla.

MASS CONS (Mass)—This property has increased actual recovery to 20 lb. per ton. Closer selection of rock necessary because of limited mill capacity explains situation. October output will be half million pounds. One Quincy furnace operates on Mass mineral full time

CENTENNIAL (Calumet)—Meeting of shareholders held this week decided to select committee to make proposal of outright sale to Osceola Consolidated, regardless of outcome of Tamarack-Calumet & Hecla deal Names of committee withheld until acceptances are certain

CALUMET & HECLA (Calumet)—Estimated output for this company and subsidiaries for 1915 is 155,000,000 lb. Costs will average for all properties about 9½c. per lb. Within two weeks another of the big furnaces at the Dollar Bay plant will go into operation. This will mean employment of 25 more men at this plant where smelter force is already 25% above normal.

Iron

LAKE ANGELINE (Ishpeming)—Shaft being repaired. Some exploratory work is to be carried on underground. Mine closed for months was recently sold to Cleveland-Cliffs Iron Co. If mining is started again new hoist will be put in. Air will be procured from Lake mine. Only rock drifts are open for passage now.

MINNESOTA

Cuyuna Range

HILLCREST (Ironton)—Viaduct and approaches now being installed for Northern Pacific spur to enter property.

Mesabi Range

ALEXANDRIA (Chisholm)—Shaft now down to orebody, drifting begun.

LAMBERT (Hibbing)—Preparations being rushed for opening this new property.

UTICA (Hibbing)—New shaft now being put down, and old shaft being repaired.

HAROLD (Hibbing)—New engine and dry house being built by Arthur Iron Mining Co.

LAMBERT (Hibbing)—Butler Bros. will start stripping this property within few days. Contract was let this week.

GRANT (Buhl)—Butler Bros. will strip 1,500,000 cu.yd. of overburden here this winter. Mine was heavy shipper this year.

GLEN (Chisholm)—Electric-haulage system new being installed. Upon its completion mine will immediately begin stockpiling.

LEONARD-BURT (Chisholm)—Large amount of test pitting now being done preparatory to greatly increasing production next season.

GRANT (Buhl)—Inter-State Mining Co., has let contract to Butler Bros. for 1,500,000 yd. additional stripping. Will require two years to complete job.

MISSOURI

EASY EIGHT (Joplin)—Has fine prospect on lease on Nelson land south of city. Operation under way for some time with little success, within the last week or two has been rewarded.

HUNTER & CO. (Joplin)—Has recently opened unusually good lead and zinc mine on Tim Malloy land, west of Joplin. Shaft is down about 85 ft. Struck first run at 75 ft.; still sinking in good ore.

MONTANA

Hill County

HAVRE NATURAL GAS (Havre)—Ditching for natural-gas pipe from well east of Havre to city, started Oct. 21. Main artery will traverse county road; laterals will be cut so as to supply every point of city.

Jefferson County

PICNIC GULCH DEVELOPMENT (Wickes)—Company, consisting of Butte mining men recently organized to develop group of four claims near Wickes. Claims show copper and are part of holdings of Wickes-Corbin Copper Co. New management expects to be taking out ore within month.

Silver Bow County

DAVIS-DALY (Butte)—Development work on the 2,500-ft. level of Colorado mine continues to prove satisfactory and orebodies opened up so far show indications of continuing. Total tonnage for October between 2,500 and 3,000 tons, average 7 to 8% copper. Planned to change shaft between 1,700 and 1,900-ft. levels, where it has but one compartment, by constructing two additional compartments, making entire shaft a three-compartment shaft from top to 2,500-ft. level.

ANACONDA (Butte)—Extensive preparations made for development of 70 acres of unexplored ground recently acquired, lying south of its Belmont mine and of Davis-Daly property. It is understood crosscut will be run from Belmont shaft into new territory and under property taken over by company on 40 years' lease. It lies in a part of Butte district that has attracted a great deal of attention following Davis-Daly opening of its 2,500-ft. level. Rumors that company is to take over Butte-Duluth getting more persistent.

BUTTE & GREAT FALLS (Butte) — With arrival of big transformer Oct. 14 that is to complete power installation, it is expected unwatering 350-ft. shaft will begin at once and as soon as that is finished development work will be started. Mine is most northerly in Butte district, located about 3 mi. north of Anaconda mine. As soon as shaft is unwatered, it will be sunk to 500-ft. level and crosscut will be started from there to Genevieve vein. Crosscut on 300-ft. level which already cuts Genevieve vein will be continued to determine extent of orebody.

PLACER LITIGATION IN U. S. SUPREME COURT—On Oct. 19 U. S. Supreme Court in case of Olivia H. Hopkins, Washington-Butte Mining Co. and Anaconda Copper Mining Co. against Frank Walker and 20 others, granted the latter 20 days in which to file brief in answer to appellant's brief asking supreme court to review action of U. S. district court of Montana in this litigation. Suit involves title to portions of Butte and Boston placer mining claim in the Butte district, lands in controversy having been held by aforesaid mining companies for more than 20 years, but are now claimed by Walker and others under lode filings. Lower court held it

had no jurisdiction and supreme court is asked to take jurisdiction and to sustain title of mining companies.

BUTTE & SUPERIOR (Butte)—In answer to inquiries as to probable effect of pending litigation between Elm Orlu and Butte & Superior, Hayden, Stone & Co., closely connected with management of company, has issued statement to effect that ground under dispute comprises not more than 25% of Butte & Superior's holdings on main Rainbow lode; this ground has not been touched by either company for mining purposes since present management came into control, nearly 4 years ago. Should Butte & Superior be defeated in suit, this would entail no loss as regards present earning capacity. Should it win its claim to disputed ground, this would add just so much to workable area of property.

NEVADA

Esmeralda County

GOLDFIELD CONSOLIDATED (Goldfield)—During September total production was 32,500 tons, from which resulted net realization of $112,847. There were 2,204 ft. of development work performed during month at cost of $4.60 per foot.

NEW GOLDFIELD SIMMERONE (Goldfield)—In a short raise above 100-ft. level 4 ft. of $300 ore has been opened. Drifts on the 100-ft. and 250-ft. levels are being extended to catch extension of shoot.

REORGANIZED KEWANAS (Goldfield)—On 838-ft. level about 300 ft. northerly from main winze an east crosscut passed through 45 ft. of vein matter showing stringers assaying from $10 to $50 per ton and exposed about 12 in. of $20 ore on hanging wall. Another east crosscut is being started 75 ft. farther north from same drift.

Nye County

TONOPAH ORE PRODUCTION for week ended Oct. 23, totaled 9,704 tons valued at $200,632. The producers were: Tonopah Belmont, 2,919 tons; Tonopah Mining, 2,850; Tonopah Extension, 1,850; Jim Butler, 1,050; West End, 760; miscellaneous leasers, 275 tons. Bullion shipments amounted to about $177,000.

MONTANA TONOPAH (Tonopah)—About 45 men are engaged operating various leases. Several hundred tons of ore shipped first half of October varied from $25 to $50 per ton.

PIONEER CON. MINES CO. (Pioneer)—Scale of operations to be increased on Nov. 1 and mill to be operated continuously. Present production is from above depth of 250 ft. and from stopes varying from 5 ft. to 20 ft. in width.

MANHATTAN DEXTER (Manhattan)—Milling of 37 tons of ore extracted by Glavinich-Choklat lease on extension of Shea vein in Union Nine Claim gave amalgam return of $1,150; average of $31 per ton from plates; milling made in War Eagle mill under the supervision of J. J. Griffith.

SUNSET MINING AND DEVELOPMENT (Rhyolite)—Mill now treating 50 tons per day of $4 to $10 ore. Installing additional equipment to raise capacity of plant to 100 tons per day. Main tunnel now in 2,200 ft. with 800 ft. farther to go to cut Denver vein. Present output is from Hobo and Eclipse veins.

MANHATTAN M. AND O. (Manhattan)—Plan for consolidation of main producing properties on Litigation Hill, with Manhattan Milling and Ore Co.'s plant to be included in merger, so that as soon as operation is started new company will be able to treat its ores in its own mill, and thus do away with high custom-mill rates, is well under way.

Storey County

ANDES (Virginia)—Explored old stopes above 175 level and put in chutes; ore will be taken through Central tunnel.

MEXICAN (Virginia)—Face of southwest drift 2,500 level shows 2 to 3 ft. of quartz of low assay value. East crosscut No. 2-A started on 2,700 level. Mill crushed 286 tons of ore averaging $13.38 per ton.

CROWN POINT-BELCHER (Gold Hill)—Water now 60 ft. below 1,600 station; 37 cars mill rock saved from No. 1 raise on Belcher 1,300 level and 9 cars of fill on 1,400 level. Jacket mill received 880 tons dump rock and 91 tons mine rock and shipped 1 bar bullion.

SIERRA NEVADA (Virginia)—Jointly with Union opening southwest drift on 2,500 level to Union shaft station and raising to 2,450 level. Sierra Nevada west crosscut on 2,500 level advanced 15 ft.; ore from $11 to $130 per ton; face in ore averaging $130, with no indication of passing through the vein.

CON. VIRGINIA AND OPHIR (Virginia)—West crosscut on 2,700 level to pick up east vein was continued. Ophir 2-compartment winze 2,500 level sunk 5 ft. on vein; saved 10 cars of ore averaging $7.80 per ton. Central tunnel vein 250 ft. level now 2 sets wide.

UNION CON. (Virginia)—Raise in No. 1 stope 2,500 level extended 5 ft.; north end in ore averaging $79 per ton; Central averaging $12; south end in good milling ore. Face of north drift from 42-ft. point in raise samples $898 per ton. Saved from this stope 108 cars of ore averaging $26.90 per ton; from No. 3 stope extracted 17 cars averaging $10.26 per ton.

NEW MEXICO

Grant County

WALDO (Lordsburg)—Operation of lead mill has ceased. Company will do mining on small scale and later resume milling operations.

CARLISLE MINE (Steeplerock)—Operations suspended pending purchase and arrival of larger mining equipment. Work on Jim Crow will be resumed.

ECLIPSE MINING AND MILLING CO. (Steeplerock)—Company has been organized by Messrs Kalar, Waite, Watson and Allen to operate property owned by G. A. Kalar in Steeplerock district.

AZURE MINING (Tyrone)—Contention mine in Tres Hermanas Mountains of Luna County, has been taken over by Azure Mining Co., from Dr. S. D. Swope. Azure interests busy in Tres Hermanas. M. L. and J. Doby are sinking shaft on contract for company.

JOHNNIE BULL EXTENSION (Steins)—Mine being operated by Moffitt and Creswell. Shipments being made to smeltery. Excellent grade of copper ore has been developed. Consolidation of copper properties in Steins section pending. May be purchased by Globe, Ariz., capitalists who have been over ground.

Lincoln County

MEHRMANN (Jicarilla)—Strike of sulphide ore carrying gold made by Wm. Mehrmann on Prince Albert claims.

WRIGHTMAN MINES (White Oaks)—Sale is reported to be completed whereby Richard Wrightman takes over practically all producing property in White Oaks region including North and South Homestake, Old Abe, C. A. Stevens and others. Reports state option alone has been granted.

NEW YORK

Niagara County

E. I. DU PONT DE NEMOURS POWDER CO. (Wilmington, Del.)—Will build $500,000 electro-chemical plant at Niagara Falls.

UTAH

Juab County

TINTIC ORE PRODUCTION for week ended Oct. 23 amounted to 121 carloads, estimated at 6,050 tons valued at $150,000, compared with 124 carloads week previous.

Summit County

PARK CITY ORE PRODUCTION for week ended Oct. 23 amounted to 1,921 tons valued at $76,000, compared with 1,614 tons week previous.

SILVER KING COALITION (Park City)—Because of strike, Oct. 26, mines have been closed. An open shop has been in vogue at Park City and this is first labor trouble here in many years.

VIRGINIA

Norfolk County

NORFOLK SMELTING CO. (West Norfolk)—Is smelting low-grade copper, silver and gold ores obtained from Cuba, Venezuela, west coast of South America, Missouri, Central West and Atlantic seaboard as far north as Canada. In connection with this plant, company is completing and putting into operation byproduct sulphuric-acid plant.

CANADA

British Columbia

RETURNS OF PLACER GOLD for province will be higher this year than last. Increase is shown in output of Atlin and Cariboo and considerable gold is being received from points tributary to Grand Trunk Pacific Ry.

NOONDAY (Sandon)—New tunnel is to be commenced and 6-drill compressor installed. New buildings have been constructed on property and surveys made for pipe line.

ENGINEER GROUP (Atlin)—Mill operated by Capt. Alexander yielding from $10,000 to $15,000 a month. Ore is free milling. On Gleaner group, adjoining Engineer, development is being carried on, and a shipment of gold ore is being made to smeltery.

GLOSSY GROUP (Highland Valley)—S. P. Dunlevy, interested in bond on this property given by J. W. Burr and others of Ashcroft, states that 22 men are employed doing development work. Shaft is down 26 ft. and shows 5 ft. of ore assaying $28 per ton mainly in copper. Car of ore being shipped to Tacoma smeltery this month.

Ontario

SCHUMACHER (Porcupine)—October production approximately $20,000.

SENECA-SUPERIOR (Cobalt)—Reported silver is being produced for 6.3c. an ounce.

McINTYRE (Porcupine)—Is increasing capacity of mill to provide for new ore that will shortly come from Jupiter.

BRUCE COPPER MINE (Bruce)—Mond Nickel Co. has taken over this property and is now shipping to its smeltery at Coniston, Sudbury District.

TOUGH OAKES (Kirkland Lake)—Made net profit of $58,000 in September. Ore being developed on 400-ft. level is richest ever discovered in mine.

PEARL LAKE (Porcupine)—Suit brought against Burr Cartwright by Louis Streuther for financial irregularities has been dismissed. This leaves property clear for McIntyre, which has bought control.

LA BELLE (Kirkland Lake)—Is name of new company with capital of $2,000,000 which has been organized to handle Loring property. Underground work has been stopped pending installation of plant. Reported vein is about 10 ft. of $15 ore.

CANADIAN COPPER (Sudbury)—Has placed all smeltery and surface men on 8-hr. basis, with same pay they formerly received for 10 and 12 hr. For small number of men whom company is unable to put on 8-hr. basis, pay will be increased. Miners who are now receiving $3.50 for 8 hr. will receive an increased wage.

DOME LAKE (Porcupine)—Has produced $86,082 since beginning of year from 9,318 tons of ore; average recovery $8.20 per ton. Mining and milling costs for period, $6.14 per ton; extraction about 80%. Subscriptions have been asked for 500,000 shares of new stock to provide money to build cyanide plant.

Quebec

TIMMINS-McMARTIN SYNDICATE (Montreal)—Has taken option on Cheney copper property near Thessalon. Taking over of this property indicates revival in district long known for its copper deposits, but abandoned for many years.

The Market Report

Metal Markets

NEW YORK—Nov. 3

All of the principal markets were distinctly stronger during the last week, a good volume of business being transacted in each case, although there was less activity in spelter than in the other metals.

Copper, Tin, Lead and Zinc

Copper—A large business was done during the week both with European and domestic consumers. With certain producers the foreign business predominated, while other producers reported the larger proportion of domestic sales. Several large contracts were entered into, covering lots of one million to four million pounds. Business in wire bars was pretty good, domestic wire drawers exhibiting considerable interest in the market. Orders for cakes also were placed freely, indicating that the rollers of copper sheets are doing a better business. It is the common belief that domestic manufacturers, generally speaking, have entered into large contracts for their goods for which they have not yet bought the raw material, while they have let their stocks run down pretty low. On the other hand, electrolytic refiners report no increase in the stock at refineries.

In the early part of the week sales were made chiefly at 17⅞@18c., delivered, regular terms. Some of the producers who had sold all they wanted to at 18c. raised their asking price to 18⅛ or 18¼c., in the latter part of the week, but up to the close of the week the market had not reached such figures. At the close, a considerable quantity of copper was still offered at 18c., regular terms. In England electrolytic copper was sold at £89@89½, this being the general price of the producers. What this would net to producers here depended largely upon the freight rate, the deduction on that account being pretty large if no room previously engaged were available. The freight rate has now risen to 60s.. per ton for November-December shipments.

Tin—The price of this metal rose under the influence of rather heavy buying, which is attributed chiefly to the improvement of business in those lines wherein tin is required.

Lead—The continued large business in the early part of the week led the A. S. & R. Co. to advance its price to 4.90c., New York on Friday afternoon. Since then business has been lighter and there has been more competition for what was in sight. The market in St. Louis failed to advance in the same proportion as in New York and now stands at the usual differential. In the New York market certain producers began to shade the generally named price.

There was a good deal of discussion of the conditions which caused the price for lead in London to decline, while it advanced in New York. At one time the London price was £2 below our parity. The weakness in the London market was explained by heavy arrivals in England of lead intended for Archangel which could not be delivered at that port either for lack of freight room or the expected freezing of the harbor. This lead had to be resold in the English market. The subsequent rally in that market indicated that these supplies had been absorbed.

Spelter—The domestic business was practically nil. The foreign business was very much less in volume than in the previous week. That which was done was chiefly for delivery during the ensuing quarter, although some contracts running well into the second quarter of 1916 were made. Certain producers appeared to be willing to sell for delivery at any time in 1916 at prices far below the present market, and some transactions of that sort were made, but they were sporadic rather than general. The way that the price for prime western has maintained itself has caused much surprise. One explanation is that the supply of common spelter has not yet increased as much as was expected, owing to the conversion of so large a proportion of it into superior grades. The accumulation of unsold spelter up to the present time has been chiefly in superior grades. Brass special is quoted at 16@16½c.; high-grade intermediate, 20@22; strictly high-grade is 35c. asked, but it appears to be difficulty salable at any such price. It is impossible to quote the superior grades of spelter with any accuracy, for the official classification no longer rules, these grades of spelter fetching all kinds of prices according to their analysis in each case.

Zinc Sheets—Business has been active, sales good but with no material change in quotations. The base price for carload lots is $16 per 100 lb. f.o.b. Peru, Ill., less 8% discount.

Other Metals

Aluminum—Conditions have not changed. Stocks of foreign material are small, and the chief domestic producer declines to quote for early delivery. Prices are high, 55@57c. per lb. being asked for No. 1 ingots, New York, spot. No quotations on futures.

It is reported that negotiations are forward for the sale of the property of the Southern Aluminum Co. to parties who are said to represent the Aluminum Co. of America.

Antimony—Business continues rather active and prices are firm. Chinese and other ordinary brands are 35@36c. per lb.; while 45@46c. is asked for Cookson's.

DAILY PRICES OF METALS IN NEW YORK

Oct Nov	Sterling Exchange	Silver, Cts. per Oz.	Copper Electrolytic, Cts. per Lb.	Tin Spot, Cts. per Lb.	Lead New York, Cts. per Lb.	Lead St. Louis, Cts. per Lb.	Zinc St. Louis, Cts. per Lb.
28	4 6250	49¼	17 70 @ 17 80	34⅜	4 75	4 65 @4 70	12.50 @14.00
29	4 6538	49¼	17 70 @ 17 80	35	4.80 @4 90	4 65 @4 75	12.50 @14.50
30	4 6425	49¼	17 70 @ 17.80	35	4 90	4 70 @4 75	13.00 @14.50
1	4 6200	49¼	17.70 @ 17 90	36	4.90	4.72½ @4 77½	13.50 @14.50
2							
3	4 6350	49⅝	17.80 @ 17.90	35¼	4 87½ @4.90	4 72½ @4.77½	13.50 @14.50

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St Louis is given as the basing point. St. Louis and New York are normally quoted 0.17c apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars. Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash. The difference between the price delivered and the New York cash equivalent is at present about 0.20c. on domestic business. The price of electrolytic cathodes is 0.05 to 0.10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands. Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St. Louis being the basing market. We quote the New York price at 17c. per 100 lb. above the St. Louis price.

Silver quotations are in cents per troy ounce of fine silver.

Some current freight rates on metals per 100 lb. are: St. Louis-New York 17c.; St. Louis-Chicago, 6.3c.; St. Louis-Pittsburgh, 13.1c.

LONDON

Oct.-Nov	Silver	Copper Standard Spot	Copper Standard 3 Mos.	Copper Electrolytic £ per Ton	Copper Electrolytic Cts. per Lb.	Tin Spot	Tin 3 Mos.	Lead £ per Ton	Lead Cts. per Lb.	Zinc £ per Ton	Zinc Cts. per Lb.
28	24⅛	72⅛	72⅛	88	18 16	156¼	156	24⅛	4 98	70½	14.55
29	24 1/16	73	73⅛	88½	18.12	158¼	158¼	23⅞	4 96	71½	14.89
30	24 1/16	. .	. .	. .	. .	. .	. .	. .	. .	. .	. .
1	24⅛	75⅛	75⅛	88½	18.26	163½	162¾	23⅝	4.87	73	15.07
2	24 3/16	74⅛	74⅛	89	18.36	161	159¾	24	4 95	75	15.48
3	24¼	74½	75	89	18 41	162½	161½	24½	5.06	76	15.69

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 3 per cent. discount. For convenience in comparison of London prices, in pounds sterling per 2240 lb., with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4.80. £15 = 3.21c.; £20 = 4.29c.; £30 = 6.43c.; £40 = 8.57c.; £60 = 12.85c. Variations, £1 = 0.21⅜c.

Nickel—Quotations for ordinary forms are nominally 45@50c. per lb., according to size and terms of order. A premium of 3c. per lb. is charged for electrolytic nickel.

Quicksilver—An almost total lack of supplies early in the week carried the price of small lots of spot up to $105 and $110 per flask. The arrival of a large lot from California by rail eased off the market and today the New York quotation is $100 per flask of 75 lb. for large lots and $100 also for smaller orders. San Francisco reports by telegraph a firm market at $92@94 per flask. London price is £16 10s. per flask, with 2s. 6d. less quoted by jobbers.

Gold, Silver and Platinum

NEW YORK—Nov. 3

Gold—Exports from Yokohama, Japan, in the eight months ended Aug. 31 were $15,998,250; of silver, $138,144. The gold shipments were chiefly to the United States; they compare with $1,060,640 last year.

Platinum—With supplies still very scarce and no present prospect of an increase the market continues very firm, although little business is doing. Dealers quote $50@55 per oz. for refined platinum and $55@60 for hard metal. All sales are a matter of more or less negotiation.

Silver—During the last few days the demand for silver has been more active and price has advanced to 24¼d. It has not developed whether this advance has been occasioned by the Indian inquiries in conjunction with home mint orders in England, but is fair to infer there has been some outside buying.

Zinc and Lead Ore Markets

PLATTSVILLE, WIS.—Oct. 30

The base price paid this week for zinc ore was $75@80 per ton for 60% grades. The base price paid for 80% lead ore was $54@55 per ton.

SHIPMENTS, WEEK ENDED OCT. 30

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	6,489,290	201,130	485,960
Year	169,316,050	5,884,340	22,724,750

Shipped during week to separating plants, 5,584,440 lb. zinc ore.

JOPLIN, MO.—Oct. 30

Blende, high price $93; base per ton 60% zinc, premium ore $90; medium grades $85@85; lower grades $84@80; calamine base per ton of 40% zinc, carlots, $58@62.50; average selling price, all grades of zinc, $82.67. Lead, high price $55.60; base per ton of 80% metal content $50@55; average, all grades of lead, $51.84 per ton.

SHIPMENTS WEEK ENDED OCT. 30

Calamine value, the week..... 24,520; 10 months, $36,860
Lead value, the week..... 40,440; 10 months, 1,953,300

Iron Trade Review

NEW YORK—Nov. 3

The iron and steel markets are extremely active and new business is coming forward rapidly. The domestic business is increasing fast, consumers becoming anxious about getting in their contracts for 1916 business so that their deliveries will not be delayed by the rush of foreign trade.

The Pennsylvania R.R. order for rails is 175,000 tons and is divided among the Cambria, Pennsylvania, Bethlehem and Lackawanna steel companies and the Steel Corporation.

The Attorney General has taken the first steps for an appeal to the Supreme Court from the decree of the Circuit Court setting aside the suit of the Government to dissolve the United States Steel Corporation.

The stockholders of the Thomas Iron Co. at a special meeting held Oct. 28 voted to accept an offer of $3,500,000 for their property. The offer was originally $3,000,000, but a higher bid was made the day before the meeting and the purchasers raised their bid by $500,000. This will net the stockholders about $56 per share of $50 par value, after all debts are paid. The purchaser is N. C. Kachelmacher, of Hocking, Ohio, but it is not known whom he represents.

The latest statement is that W. H. Donner has exercised the option which he held on both the Pennsylvania Steel and the Cambria Steel stock owned by the Pennsylvania R.R. Co., and will therefore control both those companies.

PITTSBURGH—Nov. 3
(By Telegraph)

The position of the steel mills has not changed since the last writing, except that the demand seems to be more intensive and the pressure for finished steel greater than it was.

Buyers are still more eager to purchase finished steel products, while mills are still more reserved about making commitments. Current bookings of the mills in specifications against contracts are running much heavier than was anticipated, recent sharp advances having caused buyers to specify to the limit. The majority of large contracts for bars, plates and shapes, for instance, are at 1.25c., while the present market is firm at 1.50c., and the contracts will yield the mills' business, up to the expiration of contracts at the end of the year, that will probably require three or four months of the new year to work off.

Finished steel prices are now at an average level slightly above the highest prices reached in the last movement, which culminated in the winter of 1912-3 and prices seem to be advancing more sharply than ever. The trade is entirely at sea as to what to expect, for precedents no longer count and the demand seems to be almost unlimited.

The sensation of the week is found in the very large orders for pig iron which have been placed with the merchant furnaces, indicating that the steel companies cannot provide themselves with pig iron equal to the current demand. The Youngstown Sheet & Tube Co. is today closing for 10,000 tons of basic pig and as this finishes its purchases for the present, announcement is made of the buying which began several days ago, the total being 75,000 tons of basic and 25,000 tons of bessemer for delivery up to April 1, 1916, at $15.50 Valley furnace for the basic and $16 Valley for the bessemer. The Jones & Laughlin Steel Co. is understood to have bought 30,000 tons of basic iron, the Allegheny Steel Co. 12,000 tons of basic, the Republic Iron and Steel Co. 8,000 tons of bessemer, making the total purchases of bessemer and basic iron now reported for Pittsburgh and Valley steel mills 150,000 tons. There have also been purchases of about 75,000 tons by Ohio River steel interests, including the Wheeling Steel & Iron, the Portsmouth Steel, the Newport Steel and the American Rolling Mill Co. The market today is very strong at $15.50 Valley for basic and $16 Valley for bessemer pig. With the prospect that should any considerable demand in addition come forward, it will advance the market to $16 for basic and $16.50 or $17 for bessemer iron. The buying movement so often predicted seems to have fully set in.

IRON ORE

Rather active inquiries have been made in the East for low phosphorus ore, which is just now in demand. It is said that one lot of 10,000 tons Spanish ore has been sold to a Pennsylvania furnace at about 10c. per unit, delivered.

COKE

Coke production for the past week in the Connellsville region is reported by the "Courier" at 428,319 short tons; shipments, 437,548 tons. Shipments of Greensburg and Upper Connellsville districts, 43,995 tons.

On appeal from the Court of Common Pleas the Supreme Court of Pennsylvania has decided that the law of 1913, taxing anthracite coal produced, is unconstitutional. The money collected under this act must be returned. The legislature passed a new law in 1915, and it is said that this also will be contested.

In Philadelphia Oct. 29 the final decree in the anthracite trust cases was filed in the United States Circuit Court in Philadelphia. While dismissing most of the original complaint the court maintains that the union of the Philadelphia & Reading Coal and Iron Co. and the Lehigh & Wilkes-Barre Coal Co., through the instrumentality of the Reading Co., the holding corporation, is a combination in restraint of trade and violates the anti-trust act of 1890.

Within 90 days the defendants are ordered by the decree to submit to the court a plan for the disposal by the Central Railroad Co. of New Jersey of all the stocks, bonds or other securities of the Lehigh & Wilkes-Barre Coal Co., now owned or in any manner controlled by it.

Chemicals

NEW YORK—Nov. 3

The general market is not especially active and is rather irregular in spots.

Arsenic—Business is quiet and without material change. Quotations are $3.50 per 100 lb. for large lots and $3.75@4 per 100 lb. for smaller orders.

Copper Sulphate—Business continues on a fair scale and no considerable change is noted. Quotations are $6.50 per 100 lb. for carload lots and $6.75 for smaller parcels.

Nitrate of Soda—The market is quiet and substantially unchanged. The current quotations are 2.45c. per lb. for spot and early deliveries.

The Mining Index

This index is a convenient reference to the current literature of mining and metallurgy published in all of the important periodicals of the world. We will furnish a copy of any article (if in print) in the original language for the price quoted. Where no price is quoted, the cost is unknown. Inasmuch as the papers must be ordered from the publishers, there will be some delay for the foreign papers. Remittance must be sent with order. Coupons are furnished at the following prices: 20c. each, six for $1, 33 for $5, and 100 for $15. When remittances are made in even dollars, we will return the excess over an order in coupons, if so requested.

COPPER

2082—ALASKA—The Gold and Copper Deposits of the Fort Valdez District. Bertrand L. Johnson. (Bull. 622-E, U. S. Geol. Surv., 1915; 49 pp., illus.)

2083—ALLOYS—Fatigue of Copper Alloys. Ernst Jonson. (Chem. Engr., Aug., 1915; 2½ pp.) Paper before Am. Soc. for Testing Materials. 40c.

2084—ARIZONA—Advances Made in the Metallurgy of Copper Globe District, Arizona. L. O. Howard. (Advance copy, Internat. Eng. Congress, Sept., 1915; 3 pp.)

2085—ARIZONA—Mining and Haulage in Clifton-Morenci Districts. F. B. Hanchett. (Min. and Eng. Wld., Sept. 4, 1915; 4 pp., illus.) 20c.

2086—ARIZONA COPPER MINERS' STRIKE. (Eng. and Min. Journ., Oct. 9, 1915; 2¾ pp., illus.) An account of conditions as they existed in the early part of October. 20c.

2087—BORONIZED CAST COPPER. Dr. E. Weintraub. (Advance copy, Internat. Eng. Congress, Sept., 1915; 4 pp., illus.)

2088—BRITISH COLUMBIA—Granby Consolidated Mining, Smelting and Power Co. (Min., Eng. and Elec. Rec., July, 1915; 2½ pp., illus.) 20c.

2089—CHILE—American Enterprise in South America. J. P. Bushnell. (Pan. Amer. Union, Aug., 1915; 9 pp., illus.) Notes on Chuquicamata. 40c.

2090 — CONCENTRATION — Notes on Concentration at Nevada Consolidated Copper Co. (Met. and Chem. Eng., Oct. 15, 1915; 1¼ pp., illus.) 40c.

2091—ELECTROMETALLURGY—Neuerungen in der Elektrometallurgie des Kupfers. Franz Peters. (Glückauf, Sept. 4 and 11, 1915; 9½ pp.) Continuation of article previously indexed.

2092 — FETTLING REVERBERATORIES. Henry L. Charles. (Eng. and Min. Journ., Oct. 16, 1915; 1 p.)

2093—LEACHING COPPER ORES. W. L. Austin. (Advance copy, Internat. Eng. Congress, Sept., 1915; 62 pp.)

2094—METALLOGRAPHY of Copper. William Campbell. (Advance copy, Internat. Eng. Congress, Sept., 1915; 16 pp., illus.)

2095—METALLURGICAL PLANTS—Improvements in Design and Construction of Modern Copper Plants. Chas. H. Repath. (Advance copy, Internat. Eng. Congress, Sept., 1915; 19 pp.)

2096—METALLURGY—Quelques Progrès de la Métallurgie en 1913 et 1914. M. L. Durand. (Rev. de Met., May, 1915; 29 pp., illus.)

2097—MEXICO—Mining District of Asientos, Aguascalientes. (Mex. Min. Journ., Aug., 1915; 1¼ pp.) 20c.

2098—NEW MEXICO AND TEXAS—Gold, Silver, Copper, Lead and Zinc in New Mexico and Texas in 1914. Chas. W. Henderson. (Mineral Resources of the U. S., 1914—Part I., Sept. 23, 1915; 32 pp.)

2099—REDUCTION WORKS—Copper Queen Consolidated Mining Co., Douglas, Ariz. Forest Rutherford. (Advance copy, Internat. Eng. Congress, Sept., 1915; 4 pp.)

2100—REFINING—The Development of Electrolytic Copper Refining. Lawrence Addicks. (Advance copy, Internat. Eng. Congress, Sept., 1915; 7 pp.)

2101—SMELTING—Advances in Copper Smelting. Frederick Laist. (Advance copy, Internat. Eng. Congress, Sept., 1915; 14 pp.)

2102—SMELTING—Notes on Reverberatory Smelting Practice of Nevada Consolidated Copper Co. (Met. and Chem. Eng., Oct. 1, 1915; 1 pp.) 40c

2103—SOUTH DAKOTA AND WYOMING—Gold, Silver, Copper and Lead in South Dakota and Wyoming in 1914. Chas. W. Henderson. (Mineral Resources of the U. S., 1914—Part I, Sept. 24, 1915; 16 pp.)

2104—SOUTHWEST—Copper Metallurgy of the Southwest. James Douglas. (Advance copy, Internat. Eng. Congress, Sept., 1915; 8 pp., illus.)

2105—SULPHIDES of Copper, The. Eugene Posnjak, E. T. Allen and H. E. Merwin. (Econ. Geol., Sept.-Oct., 1915; 44 pp., illus.) Thermal, chemical, microscopic and crystallographic studies. 60c.

2106—WAR—The Position of Copper During the War. John B. C. Kershaw. (Min. and Eng. Rev., July 5, 1915; 2¾ pp., illus.) 40c.

GOLD AND SILVER—GEOLOGY

2107—ALASKA—The Gold and Copper Deposits of the Fort Valdez District. Bertrand L. Johnson. (Bull. 622-E, U. S. Geol. Surv., 1915; 49 pp., illus.)

2108—ARIZONA—Gold Deposits Near Quartzsite, Arizona. Edward L. Jones, Jr. (Bull. 620-C, U. S. Geol. Surv., Sept. 23, 1915; 15 pp., illus.)

2109—CANADA—Gold Deposits of Newfoundland and Labrador. J. W. McGrath. (Can. Min. Journ., Sept. 15, 1915; 1¼ pp.) 20c.

2110—DUTCH GUIANA—Gold-Bearing Quartz Veins in Dutch Guiana. J. B. Percival. (Eng. and Min. Journ., Sept. 25, 1915; 1 p., illus.) 20c.

2111—NEW SOUTH WALES—Geological Survey of the Cargo Gold Field. E. C. Andrews and M. Morrison. (Mineral Resources No. 19, N. S. W. Geol. Surv., 1915; 42 pp., illus.)

2112—NEW ZEALAND—The Cedar Creek-Mount Greenland Goldfield, N. Z. Sidney Fry. (Min. and Eng. Rev., July 5, 1915; 1½ pp.) 40c.

2113—ONTARIO—Canoe Routes and Geological Features of Kowkash District, Ontario. (Can. Min. Jour., Sept. 15, 1915; 4¾ pp., illus.) 20c.

2114—ONTARIO—Kowkash Gold District. (Eng. and Min. Jour., Oct. 9, 1915; 1 p.) From report of the Asst. Provincial Geologist of Ontario. 20c.

2115—ONTARIO—The Kowkash District, Ontario. Charles Spearman. (Can Min. Journ., Oct. 1, 1915; 3½ pp., illus.) 20c.

2116—ONTARIO—The Kowkash Gold Area. P. E. Hopkins. (Can. Min. Journ., Oct. 1, 1915; 2 pp., illus.) 20c.

2117—ONTARIO—Structural Features of the Porcupine Ore Deposits. Alfred R. Whitman. (Can. Min. Journ., Oct. 1, 1915; 8 pp., illus.) 20c.

GOLD DREDGING AND PLACER MINING

2118—ALASKA—Mineral Resources of the Chisana-White River District, Alaska. Stephen R. Capps. (Bull. 622-F, U. S. Geol. Surv., 40 pp., illus.)

2119—ALASKA—Mining in the Fairbanks and Hot Springs Districts, Alaska. Henry M. Eakin. (Bull. 622-G, U. S. Geol. Surv., 1915; 17 pp.)

2120—ALASKA—Placer Mining in Seward Peninsula. Henry M. Eakin. (Bull. 622-I, U. S. Geol. Surv., 1915; 7 pp.)

2121—ALASKA—Stoping Methods at Fairbanks. Hubert I. Ellis. (Eng. and Min. Journ., Sept. 20, 1915; 3¾ pp., illus.) 20c.

2122—CALIFORNIA—The Larsson Gold Dredge. J. Nelson Nevius. (Min. and Oil Bull., Sept., 1915; 3¼ pp., illus.) 20c.

2123—COLOMBIA—Placers of Antioquia, Colombia. Ralph W. Perry. (Eng. and Min. Journ., Oct. 9, 1915; 5 pp., illus.) 20c.

2124—VICTORIA—Report of the Sludge Abatement Board for 1914. (Dept. of Mines and Forests, 1915; 26 pp., illus.)

2125—WASHINGTON—Gold Bar Hydraulic Mine. Hubert I. Ellis. (Eng. and Min. Journ., Oct. 23, 1915; 1 p., illus.) 20c.

GOLD AND SILVER—CYANIDING

2126—CYANOGEN COMPOUNDS—Recent Advances in the Chemistry of the Cyanogen Compounds. J. E. Clennell. (Bull. A. I. M. E., Oct., 1915; 14 pp.) 40c.

2127—PLANT DESIGN—Simple Cyanide-Plant Design. S. A. Worcester. (Eng. and Min. Journ., Oct. 16, 1915; 2¼ pp., illus.) 20c.

2128—PRECIPITATES—Refining Cyanide Precipitates. H. T. Durant. (Eng. and Min. Journ., Sept. 25, 1915; 1¼ pp.) 20c.

2129—PRECIPITATION—Aluminum Precipitation at the Mill of the Butters Divisadero Company. E. M. Hamilton and P. H. Crawford. (Min. and Sci. Press, Sept. 11, 1915; 4¼ pp., illus.) 20c.

2130—PRECIPITATION—The Electrolytic Precipitation of Gold, Silver and Copper from Cyanide Solutions. G. H. Clevenger. (Advance copy, Am. Electrochem. Soc., Sept., 1915; 40 pp., illus.)

2131—SOLUTION—The Precipitating Action of Carbon in Contact with Auriferous Cyanide Solutions. W. R. Feldtmann. (Bull. 132, I. M. M., Sept. 23, 1915; 4½ pp.) Author's reply to discussion.

2132—WESTERN AUSTRALIA—Surface Equipment of the Sons of Gwalia Gold Mine, Describing Recent Additions Thereto. A. Wauchope. (Monthly Journ. Chamber of Mines of W. Aust., June 30, 1915; 6 pp., illus.) 60c.

GOLD AND SILVER—GENERAL

2133—ALASKA—Mining in the Juneau Region, Alaska. Henry M. Eakin. (Bull. 622-C., U. S. Geol. Surv., 1915; 8 pp.)

2134—ALASKA—Mining on Prince William Sound. Bertrand L. Johnson. (Bull. 622-E, U. S. Geol. Surv., 1915; 8½ pp., illus.)

2135—ALASKA—Perseverance Mine and Alaska Gastineau Mill. Robert E. Lewis. (Min. and Sci. Press, Sept. 11, 1915; 3¾ pp., illus.) 20c.

2136—CALIFORNIA—Drift Mines of California. John D. Hubbard. (Eng. and Min. Journ., Oct. 23, 1915; 1¼ pp., illus.) 20c.

2137—CALIFORNIA—The Round Lake Mine. C. P. Bowie (Min. and Sci. Press, Oct. 2, 1915; ¾ p., illus.) 20c.

2138—COLORADO—Roosevelt Drainage Tunnel, Cripple Creek, Colo. T. H. Sheldon. (Eng. and Min. Journ., Oct. 2, 1915; 4¼ pp., illus.) 20c.

2139—FLOTATION—Concentrating Gold King Ores. Warren C. Prosser. (Eng. and Min. Journ., Oct. 16, 1915; 1¼ pp., illus.) 20c.

2140—HONDURAS. C. F. Spaulding. (Mex. Min. Journ., June, 1915; 1 p.) 20c.

2141—MILLING—Gold Milling in California—A Comparison. Leroy A. Palmer. (Met. and Chem. Eng., Sept. 15, 1915; 6¾ pp., illus.) Notes on practice of Plymouth Consolidated and Black Oak Mills. 40c.

2142—MILLING—Ore Dressing on the Mother Lode. E. S. Pettis. (Min. and Sci. Press, Sept. 18, 1915; 4 pp., illus.) 20c.

2143—NEW MEXICO AND TEXAS—Gold, Silver, Copper, Lead and Zinc in New Mexico and Texas in 1914. Chas. W. Henderson. (Mineral Resources of the U. S., 1914—Part I., Sept. 23, 1915; 32 pp.)

2144—SOUTH DAKOTA AND WYOMING—Gold, Silver, Copper and Lead in South Dakota and Wyoming in 1914. Chas. W. Henderson. (Mineral Resources of the U. S., 1914—Part I., Sept. 24, 1915; 16 pp.)

2145—UTAH—The Rejuvenation of the Old Maxfield Mine. Big Cottonwood Canyon. Will C. Higgins. (Salt Lake Min. Rev., Oct. 15, 1915; 3 pp., illus.) 20c.

2146—UTAH—Wonderful Showing Being Made by the Lakeview Mining Company on Promonotory Point. Will C. Higgins (Salt Lake Min. Rev., Sept. 15, 1915; 4⅝ pp., illus.) 20c.

IRON ORE DEPOSITS, MINING, ETC.

2147—ALASKA—Iron-Ore Deposits Near Nome. Henry M. Eakin. (Bull. 622-I, U. S. Geol. Surv., 1915; 5 pp.)

2148—CUBA—The Iron Deposits of Daiquiri, Cuba. Bull., Waldemar Lindgren and Clyde P. Ross. (A. I. M. E., Oct., 1915; 20 pp., illus.) 40c.

2149—LAKE SUPERIOR—Mining Activity on the Iron Ranges. Geo. E. Edwards. (Min. and Eng. Wld., Sept. 4, 1915; 7 pp., illus.) 20c.

2150—MINNESOTA—A Survey of the Developments and Operations in the Cuyuna Iron Ore District of Minnesota. Carl Zapffe. (Advance copy, Lake Superior Min. Inst., Sept., 1915; 11 pp.)

2151—NEWFOUNDLAND'S IRON MINES. P. B. McDonald. (Can. Min. Journ., Sept. 15, 1915; 1¼ pp.) 20c.

2152—SHAFT SINKING—Grouting at the Francis Mine Shaft of the Cleveland-Cliffs Iron Co. J. R. Reigart. (Advance copy, Lake Superior Min. Inst., Sept., 1915; 16 pp., illus.)

IRON AND STEEL METALLURGY

2153—BLAST FURNACE—Chemical Principles of the Blast Furnace. J. E. Johnson, Jr. (Met. and Chem. Eng., Sept. 15, 1915; 4½ pp.) Conclusion of article previously indexed. 40c.

2154—BLAST FURNACE—Thermal Principles of the Blast Furnace. J. E. Johnson, Jr. (Met. and Chem. Eng., Oct. 15, 1915; 3 pp., illus.) 40c.

2155—BLAST-FURNACE OPERATION, Efficiency of the. Birger F. Burman. (Met. and Chem. Eng., Sept. 15, 1915; 5 pp.) 40c.

2156—BLAST FURNACE PRACTICE—Measurement of the Temperature Drop in Blast-Furnace Hot-Blast Mains. R. J. Wysor. (Bull. A. I. M. E., Oct., 1915; 10 pp., illus.) 40c.

2157—CARBON STEELS—On the Influence of Heat Treatment on the Specific Resistance and Chemical Constitution of Carbon Steels. Edward D. Campbell. (Advance copy, Iron and Steel Inst., 1915; 13 pp., illus.)

2158—CARBURIZATION OF IRON at Low Temperatures in Blast-Furnace Gases. T. H. Byrom. (Advance copy, Iron and Steel Inst., 1915; 7 pp., illus.)

2159—CAST IRON—The Control of Chill in Cast Iron. Considering the Elements Effective in the Manufacture of Malleable Castings and Chilled Car Wheels. Grafton M. Thrasher. (Bull. A. I. M. E., Oct., 1915; 10 pp., illus.)

2160—CEMENTITE—The Magnetic Transformation of Cementite, with a Note on the Magnetic Aspects of the A3 Transformation in Pure Iron. Kotaro Honda and Hiromu Takagi. (Advance copy, Iron and Steel Inst., 1915; 15 pp., illus.)

2161—CORROSION—The Influence of Different Elements on the Corrosion of Iron. L. C. Wilson. (Eng. Mag., Oct., 1915; 8¼ pp.) 40c.

2162—DIRECT PRODUCTION—Furnace for Making Steel from Ore. (Iron Tr. Rev., Oct. 14, 1915; 1⅓ pp., illus.) 20c.

2163—MALLEABLE CAST IRON, Sulphur in. R. H. Smith. (Advance copy, Iron and Steel Inst., 1915; 12 pp.)

2164—MANAGEMENT—Applying Scientific Management—I. H. K. Hathaway. (Iron Tr. Rev., Oct. 14, 1915; 4½ pp.) Paper before Am. Foundrymen's Assn.; explains purpose and accomplishments of scientific management, and its utilization in the foundry business. 20c.

2165—NEW SOUTH WALES—The Newcastle Steel Works. Opening of the Broken Hill Proprietary Company's New Works. (Iron and Coal Tr. Rev., Sept. 3, 1915; 2¾ pp.), illus.) 40c.

2166—NITROGEN—The Occurrence and Influence of Nitrogen on Iron and Steel. N. Tschischewski. (Advance copy, Iron and Steel Inst., 1915; 51 pp., illus.)

2167—OPEN HEARTH VERSUS THE ELECTRIC FURNACE in the Manufacture of Commercial Steels. Sidney Cornell. (Met. and Chem. Eng., Sept. 15, 1915; 1½ pp.) 40c.

2168—PHOSPHORUS in Iron and Steel. W. H. Hatfield. (Advance copy, Iron and Steel Inst., 1915; 13 pp., illus.)

2169—POWER—Purchased Power for the Steel Mill. C. S. Lankton. (Iron Tr. Rev., Sept. 23, 1915; 2½ pp.) From a paper before Assn. of Iron and Steel Elec. Engrs. 20c.

2170—PURE IRON—The Influence of Oxygen on Some Properties of Pure Iron. Wesley Austin. (Advance copy, Iron and Steel Inst., 1915; 5 pp., illus.)

2171—SHERARDIZING. S. Trood. (Advance copy, Am. Inst. of Metals. Sept., 1915; 11 pp.)

2172—TOOL STEEL—The Effect of Chromium and Tungsten Upon the Hardening and Tempering of High-Speed Tool Steel. Prof. C. A. Edwards and H. Kikkawa. (Advance copy, Iron and Steel Inst., 1915; 25 pp., illus.)

LEAD AND ZINC

2173—IMPURITIES—The Effect of the Common Impurities in Spelter Upon Slush Castings. Gilbert Rigg and Henry C. Morse. (Advance copy, Am. Inst. of Metals, Sept., 1915; 32 pp., illus.)

2174—METALLURGY—Quelques Progrès de la Métallurgie en 1913 et 1914. M. L. Durand. (Rev. de Met., May, 1915; 29 pp., illus.)

2175—MILL—The New Mill of the Daly West Mining Co., Park City, Utah. L. O. Howard. (Met. and Chem. Eng., Sept. 15, 1915; 5¼ pp., illus.) 40c.

2176—MISSOURI—Boom in Missouri Zinc Mining. H. B. Pulsifer. (Salt Lake Min. Rev., Oct. 15, 1915; 2¼ pp., illus.) 20c.

2177—NEW MEXICO AND TEXAS—Gold, Silver, Copper, Lead and Zinc in New Mexico and Texas in 1914. Chas. W. Henderson. (Mineral Resources of the U. S., 1914—Part I, Sept. 23, 1915; 32 pp.)

2178—SARDINIA—Calamine Mines of Sardinia. Charles W. Wright. (Eng. and Min. Journ., Oct. 16, 1915; 3½ pp., illus.) 20c.

2179—SARDINIA—Conditions and Compensation of Labor in Sardinia. Charles Will Wright. (Min. Mag., Sept., 1915; 3¾ pp.) 40c.

2180—SMELTING—Development of Zinc Smelting in the United States. George C. Stone. (Internat. Eng. Congress, Sept., 1915; advance copy.)

2181—SMELTING—The Newnam Hearth. William E. Newnam. (Advance copy, A. I. M. E., Feb., 1916; 7 pp., illus.) 40c.

2182—SMELTING AND REFINING of Lead. Dr. H. O. Hofman. (Advance copy, Internat. Eng. Congress, Sept., 1915; 5 pp.)

2183—SOUTH DAKOTA AND WYOMING—Gold, Silver, Copper and Lead in South Dakota and Wyoming in 1914. Chas. W. Henderson. (Mineral Resources of the U. S., 1914—Part I, Sept. 24, 1915; 16 pp.)

2184—TASMANIAN ZINC-LEAD SULPHIDES. The Roseberry Mines. (Min. and Eng. Rev., July 5, 1915; 3 pp.) 40c.

2185—UNITED STATES—The Future of the American Zinc Industry. Otto Ruhl. (Min. and Eng. Wld., Oct. 16, 1915; 3¼ pp.) 20c.

2186—ZINC OXIDE—Production of Zinc Oxide from Low-Grade Carbonate Ore at Leadville. (Met. and Chem. Eng., Sept. 15, 1915; 2½ pp., illus.) 40c.

OTHER METALS.

2187—ALUMINUM—A New Reagent for the Detection and Colorimetric Estimation of Aluminum. F. W. Atack. (Journ Soc. Chem. Ind., Sept. 30, 1915; 1¼ pp.)

2188—ALUMINUM—Melting Aluminum Chips. H. W. Gillett. (Advance copy, Am. Inst. of Metals, Sept., 1915; 8 pp.)

2189—ALUMINUM—Recent Developments in Aluminum. Ernest V. Pannell. (Advance copy, Am. Inst. of Metals, Sept., 1915; 22 pp., illus.)

2190—AUSTRALIA—Facts Bearing Upon the Production and Marketing of Metals in Australia. (Min. and Eng. Rev., Sept. 6, 1915; 2¼ pp.) 40c.

2192—COBALT—The Determination of Cobalt and Nickel in Cobalt Metal. C. A. Knittel. (Can. Min. Journ., Oct. 1, 1915; 1 p.) 20c.

2193—MAGNALIUM—Reclamation of Magnalium from Turnings. John Coulson. (Advance copy, Am. Inst. of Metals, Sept., 1915; 7 pp.)

2194—QUICKSILVER in 1914, Production and Resources. H. D. McCaskey. (Mineral Resources of U. S., 1914, Part 1; 18 pp.)

2195—QUICKSILVER—Some Cinnabar Deposits in Western Nevada. Adolph Knopf. (Bull. 620-D, U. S. Geol. Surv., Sept. 14, 1915; 10 pp.)

2196—TIN—Annan River Tinfield, Cooktown District, North Queensland. E. Cecil Saint-Smith. (Queensland Govt. Min. Journ., Aug. and Sept., 1915; 17 pp., illus.)

2197—TIN. Editorial. (Min. Journ., Sept. 11, 1915; 1¼ pp.) 40c.

2198—TIN—Prospects for Tin in the United States. H. Foster Bain. (Min. Mag., Sept., 1915; 4½ pp.) 40c.

2199—TIN—Visiting the Hunan Tinfields. Gilmour E. Brown. (Min. Mag., Sept., 1915; 5 pp., illus.) 40c.

2200—TIN MINING in Alaska. Henry M. Eakin. (Bull. 622-E, U. S. Geol Surv., 1915; 14 pp., illus.)

2201—TIN-ORE DRESSING at Llallagua, Bolivia. Durward Copeland and Scoville E. Hollister. (Eng. and Min. Journ., Sept. 25 and Oct. 2, 1915; 6¾ pp., illus.) Conclusion of article previously indexed. 40c.

2202—TUNGSTEN—Burmese Tungsten. E. Maxwell-Lefroy. (Engineer, Oct. 1, 1915; ⅔ p.) 40c.

2203—VANADIUM—The Manufacture and Use of Alumino-Vanadium. W. W. Clark. (Advance copy, Am. Inst. of Metals, Sept., 1915; 9 pp.)

NONMETALLIC MINERALS

2204—ASBESTOS—The Working of Asbestos. (Can. Engr., Oct. 7, 1915; 1¼ pp.) Brief outline of the industry and a list of Quebec producers. 20c.

2205—ASPHALT—The Production of Asphalt, Related Bitumens, and Bituminous Rock in 1914. John D. Northrup. (Mineral Resources of U. S., 1914—Part II; Oct. 18, 1915; 16 pp.)

2206—BORAX—The Current Status of the Borax Industry. Samuel H. Dolbear. (Met. and Chem. Eng., Sept. 1, 1915; ¾ p.) 40c.

2207—BORNITE—The Chemical Composition of Bornite. Austin F. Rogers. (Science, Sept. 17, 1915; 1¾ pp., illus.)

2208—CHROME—Resumption of Chrome-Ore Mining at Black Lake, Que. A. C. Allenson. (Can. Min. Journ., Sept. 15, 1915; 1¼ pp.) 20c.

2209—FELDSPAR—The Production of Feldspar in 1914. Frank J. Katz. (Mineral Resources of U. S., 1914—Part II; Oct. 15, 1915; 6 pp.)

2210—GEMS and Precious Stones in 1914. Douglas B. Sterrett. (Mineral Resources of U. S., Year 1914—Part II, Oct. 13, 1915; 40 pp.)

2211—GEMS—Tables for the Determination of Gems and Precious Stones or Ornamental Stones Without Injury to the Specimen. Alfred J. Moses. (Sch. of Mines Quart., Apr., 1915; 32 pp.) 60c.

2212—LIME—The Production of Lime in 1914. G. F. Loughlin. (Mineral Resources of U. S., 1914—Part II, Oct. 14, 1915; 11 pp.)

2213—MINERAL WATERS—The Production of Mineral Waters in 1914. R. B. Dole. (Mineral Resources of the U. S., 1914, Part II; 49 pp., illus.)

2214—PHOSPHATE—The Pebble Phosphates of Florida. E. H. Sellards. (From 7th Ann. Report, Fla. Geol. Surv., 1915; 92 pp., illus.)

2215—POTASH—The World's Supply of Potash (Pub. by The Imperial Institute, London, 1915; 47 pp.) An account of all the more important sources of potash in the world, including the Stassfurt deposits in Germany.

2216—POTASH SALTS, The. Editorial. (Min. Mag., Sept., 1915; 2¼ pp.) 40c.

2217—POTASSIUM SALTS: An Economic Geological Study. E. Mackay Heriot. (Eng. and Min. Journ., Oct. 23 and 30, 1915; 6½ pp., illus.) 20c.

2218—SALT, BROMINE AND CALCIUM CHLORIDE in 1914, The Production of. W. C. Phalen. (Mineral Resources of the U. S., 1914—Part II; Sept. 20, 1915; 16 pp., illus.)

2219—SULPHUR—Remarkable Development of Sulphur in Progress on Texas Coast. (Min. Congress Journ., Oct., 1915; 3½ pp., illus.) 20c.

2220—SULPHUR—The Origin of the Sulphur Deposits of Sicily. Walter F. Hunt. (Econ. Geol., Sept.-Oct., 1915; 36 pp., illus.) 60c.

PETROLEUM AND NATURAL GAS

2222—CALIFORNIA—Important Topping Plants of California. Arthur F. L. Bell. (Bull. A. I. M. E., Sept., 1915; 31 pp., illus.)

2223—GEOLOGIC CONDITIONS That May Confuse Oil Drillers. Dorsey Hager. (Eng. and Min. Journ., Oct. 9, 1915; 1 p., illus.) 20c.

2224—MEXICO—The Furbero Oil Field, Mexico. E. Degolyer. (Bull. A. I. M. E., Sept., 1915; 12¼ pp., illus.) 40c.

2225—MONTANA—Possibilities of Oil in the Porcupine Dome, Rosebud County, Montana. C. F. Bowen. (Bull. 621-F, U. S. Geol. Surv.; 10 pp., illus.)

2226—NATURAL GAS—Composition of the Natural Gas Used in Twenty-Five Cities, with a Discussion of the Properties of Natural Gas. G. A. Burrell and G. G. Oberfell. (Tech. Paper 109, U. S. Bureau of Mines, 1915; 22 pp.)

2227—OHIO—Anticlines in the Clinton Sand Near Wooster, Wayne County, Ohio. C. A. Bonine. (Bull. 621-H, U. S. Geol. Surv., Oct. 8, 1915; 12 pp., illus.)

2227a—OKLAHOMA—The Duncan Gas Field, Stephens County, Oklahoma. Carroll H. Wegemann. (Bull. 621-D, U. S. Geol. Surv., Aug. 30, 1915; 12 pp., illus.)

2228—OKLAHOMA—The Healdton Oil Field, Carter County, Oklahoma. C. H. Wegemann and K. C. Heald (Bull. 621-B, U. S. Geol. Surv.; 18 pp., illus.)

2229—OKLAHOMA—The Lawton Oil and Gas Field, Oklahoma. Carroll H. Wegemann and Ralph W. Howell. (Bull. 621-G, U. S. Geol. Surv., Sept. 27, 1915; 17 pp., illus.)

2230—TENNESSEE—Recent Oil Developments Near Oneida, Scott County, Tennessee L. C. Glenn. (Resources of Tenn., Oct., 1915; 21 pp., illus.)

2231—TEXAS—A Reconnaissance for Oil Near Quanah, Hardeman County, Texas. Carroll H. Wegemann. (Bull. 621-J, U. S. Geol. Surv., Oct. 9, 1915; 7 pp., illus.)

2232—WESTERN AUSTRALIA—The Reputed Petroliferous Area of the Warren River District. (South-West Division). H. P. Woodward. (Bull. 65, West. Aust. Geol. Surv., 1915; 54 pp., illus.)

ECONOMIC GEOLOGY—GENERAL

2233—IDAHO—The Orofino Coal Field, Clearwater, Lewis and Idaho Counties, Idaho. Charles T. Lupton. (Bull. 621-I, U. S. Geol. Surv., Oct. 9, 1915; 10 pp., illus.)

2234—IGNEOUS INTRUSIONS. T. A. Rickard. (Min. and Sci. Press, Oct. 9, 1915; 2½ pp., illus.) 20c.

2235—ONTARIO—Certain Mineral Occurrences in the Worthington Mine, Sudbury, Ontario and Their Significance. T. L. Walker. (Econ. Geol., Sept.-Oct., 1915; 7 pp., illus.) 60c.

2236—ONTARIO—Pre-Cambrian Ore Deposits in Ontario. Willet G. Miller and Cyril W. Knight. (Min. and Sci. Press, Sept. 11, 1915; 3½ pp., illus.) Abstract of paper before Royal Soc. of Canada. 20c.

2237—ORE DEPOSITION—The Fractional Precipitation of Some Ore-Forming Compounds at Moderate Temperatures. Roger C. Wells. (Bull. 609, U. S. Geol. Surv., 1915; 46 pp., illus.)

2238—TROPICS—Geology as an Aid to Tropical Engineering. Warren D. Smith. (Min. and Sci. Press, Sept. 18, 1915; 6¼ pp., illus.) 20c.

2239—UTAH—Geology of the Ore Deposits of the Tintic Mining District. Guy W. Crane. (Bull., A. I. M. E., Oct., 1915; 14 pp.)

MINING—GENERAL

2240—ACCIDENTS—Monthly Statement of Coal-Mine Fatalities in the United States, July, 1915. Albert H. Fay. (U. S Bureau of Mines, 1915; 16 pp.)

2241—AIR MEASUREMENT—Orifice Measurement of Air in Large Quantities. Elmo G. Harris. (Bull., Mo. School of Mines and Metallurgy, Nov., 1915; 18 pp., illus.)

2242—BLASTING—The Galvanometer and Its Advantages in Electrical Blasting. A. E. Anderson. (Colo. Sch. of Mines Mag., Oct., 1915; 1½ pp.)

2243—BOLIVIA—The Mineral Resources of Bolivia. (Mex. Min. Journ., June, 1915; 2½ pp.) 20c.

2244—BURMA—Mining in Burma—Part I. C. W. Chater. (Trans. N. Eng. Inst. Min. and Mech. Engrs., July, 1915; 14 pp., illus.)

2245—CONVEYING ORE—Moving Ore in Flat Stopes on the Rand. E. M. Weston. (Eng. and Min. Journ., Oct. 23, 1915; 1¾ pp., illus.) 20c.

2246—COLORADO—Mining in Colorado. George J. Bancroft. (Min. and Sci. Press, Oct. 9, 1915; 2 pp., illus.) 20c.

2247—COST—Basic Principles of Mining Cost. James R. Finlay. (Sch. of Mines Quart., Apr., 1915; 5 pp.) 60c.

2248—DRILL BITS—Comparative Tests of Piston-Drill Bits. C. R. Forbes and L. M. Cummings. (Bull. Mo. Sch. of Mines and Met., Aug., 1915; 16 pp. illus)

2249—DUST—Recent Investigations on Dust in Mine Air and the Causation of Miners' Phthisis. James Moir. (Journ. Chem., Met. and Min. Soc. of So. Afr., July-Aug., 1915; 7½ pp., illus.) 60c.

2250—EXCAVATION—Excavateur de Faible Encombrement pour Mines et Terrassements. P. Calfas. (Génie Civil, Sept. 4, 1915; 3¼ pp., illus.) 40c.

2251—EXPLOSIVES Used in War and Metal Mining. Percy E. Barbour. (Eng. and Min. Journ., Sept. 25, 1915; 4 pp.) Notes on the constituents and characteristics of different explosives. 20c.

2252—FINANCING of Mines in the United States. Lucius W. Mayer. (Advance copy, Internat. Eng. Congress, Sept., 1915; 18 pp.)

2253—FIRST AID at Ray Consolidated. J. T. More. (Eng. and Min. Journ., Oct. 9, 1915; 1½ pp.) 20c.

2254—HOISTING—The Winding Drums of Practice and of Theory; with Notes on Factors of Safety and Economy of Winding-Ropes. H. W. G. Halbaum. (Trans., N. Eng. Inst. Min. and Mech. Engrs., July, 1915; 70½ pp., illus.)

2255—HOISTING WORKS in the Park City District, Utah—I. L. O. Howard. (Min. and Sci. Press, Oct. 9, 1915; 3 pp., illus.) 20c.

2256—LABOR—Miners' Unions in Canada. (Can. Min. Journ., Sept. 15, 1915; 3¼ pp., illus.) Continuation of article previously indexed. 20c.

2257—MEXICO—New Mining Taxes in Mexico. Editorial. (Eng. and Min. Journ., Oct. 23, 1915; 1½ pp.) 20c.

2258—MEXICO—Zacatecas. (Mex. Min. Journ., Aug., 1915; 1½ pp.) 20c.

2259—NEWFOUNDLAND'S MINERAL RESOURCES. P. B. McDonald. (Eng. and Min. Journ., Oct. 23, 1915; 1¾ pp., illus.) 20c.

2260—ORE POCKET—Concrete Underground Ore Pocket at Copper Queen. Fred M. Heidelberg. (Eng. and Min. Journ., Oct. 2, 1915; 2¼ pp., illus.) 20c.

2261—RESCUE WORK—The Instruction, Organization and Care of Rescue Parties Using Self-Contained Breathing-Apparatus in Mines After an Explosion, or in Fighting Mine Fires. George O'Brien. (Bull. Can. Min. Inst., June, 1915; 7 pp.)

2262—SHAFT-SINKING with Jackhamers. Leroy A. Palmer. (Eng. and Min. Journ., Oct. 9, 1915; 1½ pp., illus.) 20c.

2263—SKIP with Cable Guides. Jesse Simmons. (Eng. and Min. Journ., Sept. 25, 1915; 1 p., illus.) 20c.

2264—SURVEYING—Use of the Brunton in Mine Surveying. James O. Greenan. (Mex. Min. Journ., Sept., 1915; 1½ pp.) 20c.

2265—TIMBERING in New York Subway. John Seward. (Eng. and Min. Journ., Oct. 23, 1915; 1 p.) Correspondence discussing P. E. Barbour's article previously published. 20c.

2266—TIMBERING in the New York Subway. Percy E. Barbour. (Eng. and Min. Journ., Oct. 2, 1915; 2¼ pp., illus.) Discusses the causes of two disasters in New York subway building, and suggests that better timbering would have prevented them. 20c.

2267—TUNNELING AND GEOLOGY. E. Lauchli. (Can. Engr., Sept. 16, 1915; 7½ pp., illus.) The importance of geologic surveys in connection with tunnel work. 20c.

2268—UTAH—Mining in Utah. L. O. Howard. (Min. and Sci. Press. Sept. 18, 1915; 2¾ pp., illus.) 20c.

2269—VALUATION of Mines. Editorial. (Min. and Sci. Press, Oct. 9, 1915; 1 p.) 20c.

2270—VENTILATION—Economy in Ventilating Mines with Purchased Power. Thomas A. Mather. (Coal Age, Sept. 4, 1915; 1½ pp.) 20c.

ORE DRESSING—GENERAL

2271—CONCENTRATING TABLE—Wright Concentrating Table. C. W. Wright. (Eng. and Min. Journ., Oct. 16, 1915; 2 pp., illus.) 20c.

2272—CRUSHING—Kick vs. Rittinger: An Experimental Investigation in Rock Crushing, Performed at Purdue University. Arthur O. Gates. (Bull. A. I. M. E., Sept., 1915; 29 pp., illus.) 40c.

2273—FLOTATION—Callow Pneumatic Process of Flotation. (Met. and Chem. Eng., Sept. 1, 1915; 2 pp., illus.) 40c.

2274—FLOTATION—Methods of Handling Waste Products from Mills in Australia. W. Shellshear. (Min. and Eng. Rev., Sept. 6, 1915; 5 pp., illus.)

2274a—FLOTATION—Recent Progress in Flotation. (Min. and Eng. Rev., Sept. 6, 1915; 2½ pp., illus.) 40c.

2276—FLOTATION—What Is Flotation? T. A. Rickard. (Min. and Sci. Press, Sept. 11 and Oct. 2, 1915; 8 pp., illus.) 40c.

2276—FLOTATION—Why Is Flotation? Charles T. Durell. (Min. and Sci. Press, Sept. 18, 1915; 4 pp.) 20c.

2277—FLOTATION—Use of Coal Tar in Flotation. William A. Mueller. (Eng. and Min. Journ., Oct. 9, 1915; 3 pp.) 20c.

2278—FLOTATION OILS—Grades and Kinds of Oil for Flotation Processes. (Min. and Eng. Wld., Sept. 25, 1915; 1½ pp., illus.) 20c.

METALLURGY—GENERAL

2279—ALLOY—Standard Test Specimen of Zinc-Bronze: Cu, 88; Sn, 10; Zn, 2. Henry S. Rawdon. (Advance copy, Am. Inst. of Metals, Sept., 1915; 15 pp., illus.)

2280—ALLOY—Stellite. Elwood Haynes. (Advance copy, Am. Inst. of Metals, Sept., 1915; 4 pp.)

2281—ALLOY—The Advantages of a Standard Railroad Car-Bearing Alloy. Russell R. Clarke. (Advance copy, Am. Inst. of Metals, Sept., 1915; 19 pp.)

2282—ALLOY—The Development of an Acid-Resisting Alloy. S. W. Parr. (Advance copy, Am. Inst. of Metals, Sept., 1915; 7 pp., illus.)

2283—ALLOYS—Aluminum Bronze Alloys. W. M. Corse. (Advance copy, Am. Inst. of Metals, Sept., 1915; 11 pp., illus.)

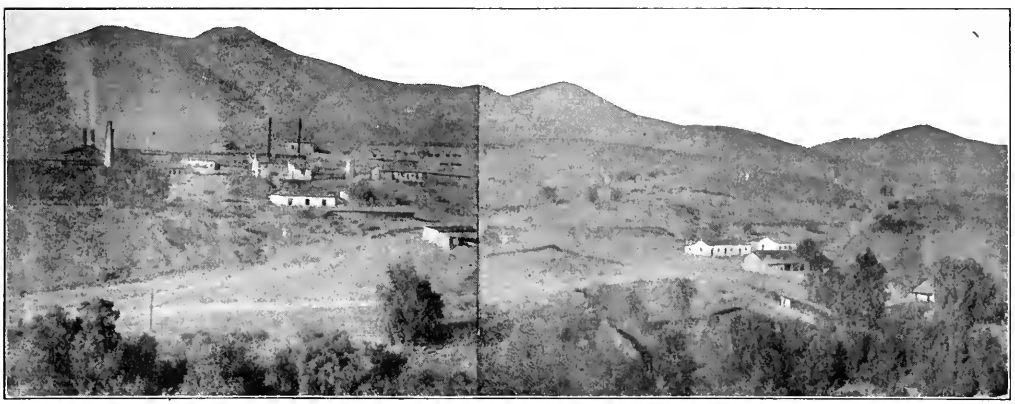
Smelting at Panulcillo, Chile

SPECIAL CORRESPONDENCE

SYNOPSIS—An account of the smelting operations of the Central Chili Copper Co. at Panulcillo in the province of Coquimbo. Besides the ore of its Panulcillo mine, the company smelts custom ores, for which a bedding system is provided. An unusual charge-track arrangement is employed.

The Central Chili Copper Co. was the outcome of the reorganization of the Panulcillo Copper Co., which began operations about 50 years ago at Panulcillo, in the province of Coquimbo, Chile. The company is owned by French and English capital and is under the management of Berthold Schiff, a native of France, who has had a wide experience in Mexico and Latin-American countries. The mining operations are in charge of Charles Gibbons, and the smelting plant is under the direction of Thomas F. Higgins, formerly with the United States Smelting Co., at Midvale, Utah, assisted by R. L. Lee, formerly with Mason Valley Mines Co., of Thompson, Nev.



GENERAL VIEW OF CENTRAL CHILI COPPER CO. AT PANULCILLO

WORKS IN CENTER OF COQUIMBO ORE DISTRICT

The smelting plant of the Central Chili Copper Co. is situated in the center of the Coquimbo ore district, being 78 km. from the port of Coquimbo and 42 km. from Ovalle. On account of its central location, the plant is able to secure ores from all the surrounding districts without incurring a heavy freight rate. There are two other smelting plants in the district, but they do little or no custom smelting.

The Central Chili Copper Co.'s plant is at an elevation of 1,200 ft. above the sea, out of the zone of heavy rains, and below that of snow or freezing weather. Consequently, little housing of the plant is necessary. The present furnace of the Herreshoff type has a capacity of about 250 tons a day and was installed by H. K. Masters in 1905, replacing three old-style furnaces.

CUSTOM ORES ARE BEDDED

The company operates the famous Panulcillo mine, situated about 2 km. from the smelting plant. A little more than 50% of the ore smelted is from this mine. The remainder of the charge is made up of purchased ores, carbonates and oxides, from various parts of the district, and as they are of a wide variety, a bedding system is necessary. The *Journal* of May 15, 1915, published an illustration of the beds made at the Central Chili Copper Co.'s plant by dumping the ore sacks brought in by burro troop. As this system was modernized some time ago, a description of the bedding system now in use may be of interest.

The Panulcillo mine is connected with the smelting plant by a gravity incline, and the ore is brought down in 3-ton bottom-dump cars. While about 2% of the custom ores still arrives on burros and is dumped to the pile direct, the other 98% arrives in railroad cars, mostly of 20 tons' capacity, having flat bottoms. In one of the accompanying illustrations the bedding system is shown with two trestles, 125 ft. long. These are 12 ft. higher than the feed-floor level and have a track for the charge cars which run along either side.

When the custom ores arrive at the plant, they are shoveled over the side of the car, commencing at one end of the trestle and moving forward as the unloading proceeds, so as to give an even layer from the contents of each car. As the ore falls on the apex of the bed and rolls to either side, a fair mixture is obtained. From the two trestles four beds of 900 tons each can be made. This storage capacity, about 3,600 tons, is ample for this plant.

The sampling of the ores is done in a primitive way, but it is the method used in most parts of Chile and seems to give satisfaction both to buyer and to seller. As the ore is unloaded from the cars, every 20th shovelful is taken for a sample. This is passed through a Sturtevant jaw crusher and then over a divider, after which it is quartered and bucked in the usual manner. Owing to the great number of different ores arriving each day, it is almost impossible to get an analysis of all the ore placed on a bed before it is smelted. In making up the furnace charge, the percentage of iron and sulphur in the bed is taken into consideration, since by knowing these two factors the metallurgist accustomed to the ores of the district is able to judge of the proportions of the furnace mixture. Any alteration that may be required can be made as soon as the slag has been examined. Once the bed or mixture is adjusted to produce the right slag, there is seldom any need to change the charge until the next bed is opened.

Coke is bought in England and shipped in sailing vessels, the voyage from England to Coquimbo taking about one hundred days. Before the war German coke was used. Arriving in Coquimbo, the coke is unloaded on stockpiles. Because of the uncertain arrival of the ships it is necessary to carry a large stock of coke at all times. Shipment from stockpile at Coquimbo is made in 7-ton railroad cars as needed for the furnace. The coke is unloaded at the smelting plant in a manner similar to that for ore, the space provided for coke having a capacity of 300 to 400 tons, thus compensating for any irregularity in the arrival of the coke trains.

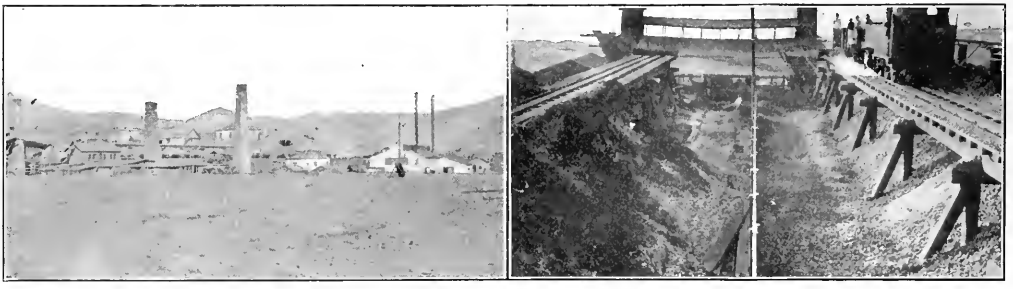
Transfer Car and "Change Track" Permit Use of Charge-Car Tracks Without Curves

In handling the furnace-charge cars an unusual method is used. By installing a "change track" and a transfer car, all curves in the charge tracks were eliminated. The ore beds, the sulphide ores and the coke piles are all made parallel to the axis of the furnace. The so-called change track, 200 ft. long, runs at right angles and is 2 ft. lower than the charge track. On the change track runs a flat car, the top of which is on a level with the rails of the charge-car tracks.

Side-dump charge cars of 2½ tons' capacity are used for the ores and smaller cars of the same type for the coke. The coke and ores are shoveled into the cars from the floor of their respective beds. After filling, the cars are pushed out to the change track, run on the flat, or transfer, car and then to charge tracks on either side of the furnace. The charge cars pass over scales on the way to the furnace, are weighed and run to the charge doors. At first thought, this appears to be an expensive method of handling charges, but when the cheapness of labor is taken into consideration, it is not found to be expensive. The cost of taking ore from the beds to the furnace is less than 4c. per ton.

Sow Difficulties in the Blast Furnace

The blast furnace at the Central Chili Copper Co.'s plant measures 46x144 in. at the tuyeres and has a height of 9 ft. There are four jackets on each side and one jacket at the ends. The side jackets have three tuyeres each. A copper breast jacket is used, and a water-jacketed steel spout, with water-cooled copper nose-piece,



TWO VIEWS OF THE SMELTING PLANT AT PANULCILLO, PROVINCE OF COQUIMBO, CHILE

traps the blast 5 in. All jackets, as well as the spouts, are made at the plant. The copper breast jackets and nose-pieces were formerly purchased in New York. Lately, however, a small reverberatory furnace, 2 ft. wide and 4 ft. long, has been constructed, and in this the old breast jackets and scrap copper are melted and the copper poured into the molds for the new breast jackets and nose-pieces.

The bottom of the blast furnace is lined with silica brick, but on account of difficulties with iron "sows," the problem is to prevent the bottom from becoming too high rather than from burning out. In the two years' run on the present bottom there has not been one break-out in the bottom of the furnace.

The forehearth is 8 ft. in width and 15 ft. in length and is made of ¼-in. steel, lined with crushed siliceous ore, the bottom being of slag brick. When necessary the settler is cooled by a water spray, but the latter is sometimes not used for several days. Owing to accumulations of iron sow, the bottom of the settler gradually builds up and it becomes necessary to raise the tap hole from time to time. After a run of 30 to 40 days it is usually necessary to change settlers. This is done by breaking the joints on each side, where the sheets are put together with bolts instead of rivets. The frame is then taken

away in pieces and the sow raised with jacks in order to permit it to be taken out on rollers. Changing the settler necessitates shutting down the furnace for two days, during which time any necessary repairs are made. Small forehearths of the type formerly used at Trail, B. C., were tried, but it was found that sow difficulties were greater with the small settler than with the large one. The settler sow, when cooled, is blasted, broken into pieces small enough to enter the furnace doors and resmelted at times when the furnace is in good condition. The smelting of the sow in small quantities does not seem to make any increase of sow in the settler. The sow usually contains about 40% Fe and 40% Cu.

The Slag Is High in Alumina

About 7,000 tons of ore are smelted per month, and an average slag analysis is as follows: SiO_2 40.9%; Fe 15.6; CaO 12.3; Al_2O_3 22.8; MgO 1.1; Cu 0.43%. The slag is hauled to the dump in small hand-tilted pots drawn by mules or horses. It is under consideration, however, to replace the animals with mechanical traction. The matte is tapped from the settler into cast-steel molds, each mold holding about 300 lb. of matte. When cooled it is passed through a Blake crusher and put into sacks containing about 220 lb. each and shipped to New York. The grade of the matte is maintained as near 50% as possible, as this grade has been found most economical.

Flue dust was previously wet and fed back to the furnace while running under low blast. Recently an Empress briquetting machine has been installed, and in the future the flue dust will be briquetted with some of the finer ores which contain sufficient talcose material to act as a binder.

The power-house equipment comprises two Garrett compound engines of 225 hp. each, running at a speed of 187 r.p.m., direct-connected to three-phase generators. Only one engine is run at a time, the other being kept in reserve in case of breakdown, or to give time for cleaning the boilers. The power is distributed through different motors about the plant, there being a 60-hp. motor for the matte crusher, a 15-hp. motor for each of two pumps and another of the same size for the sampling mill, an 80-hp. motor for the briquetting plant, and a 100-hp. motor for the furnace blower. The blower is a No. 7 Connersville and delivers air to the furnace at a pressure of 20 oz.

The smelting plant is operated in 12-hr. shifts and, including the mechanical department, employs about 200 men. The men are paid from 2½ to 4½ pesos per day, except the mechanics, who receive from 4½ to 8 pesos. As the Chilean peso has a value of about 18c., U. S. Cy., according to the present rate of exchange, hand labor is in most cases cheaper than mechanical operations. Therefore much of the work is done by hand.

When labor is cheap one is usually inclined to think that it is inefficient. On the contrary, some of the men at this plant are excellent workers, and as a whole one might compare them to the Greek laborers used in some of the plants in the western part of the United States. As an example of the efficiency of these workers, it may be mentioned that a gang at Panulcillo unloads 20 tons of ore per man for a day's work, and the charge wheelers will load and put to the furnace 20 tons per man per day. Yard men working by task will do as much as the average workman of this class in the United States. As for mechanics, one may encounter much worse in the States.

In closing, it may be of interest to mention that the Central Chili Copper Co. was one of the few mining or smelting establishments of Chile that withstood the general crisis in 1914 and worked without interruption after the outbreak of the European war.

TRANSPORTING MOLTEN SLAG AND "CLEANUP" AT THE PANULCILLO PLANT

Slag is hauled from the blast furnace by animals at present. The substitution of mechanical traction has been under consideration for some time, but up to date no installation has been made.

Method of elevating "cleanup" to the furnace-feed floor. The "angarillas" hold about 250 lb. each. Because of the cheap labor and the small quantity of material to be handled, an elevator is not installed.

Asphalt in the United States

Since 1907 the output of manufactured asphalt from domestic sources has dominated the asphalt industry of the United States, says the United States Geological Survey. The quantity of manufactured asphalt from domestic petroleum reached 360,383 tons in 1914, with another 313,787 tons produced from Mexican petroleum, as against a total production of natural asphalt of 77,588 tons. This latter was subdivided as follows: Bituminous rock, 48,771 tons; wurtzilite (elaterite) and gilsonite, 19,148; and grahamite, 9,669 tons. This was produced by the states of California, Kentucky, Oklahoma and Utah. Although ozokerite occurs in Utah, the United States has for years imported practically all its supply from Galicia.

Production of Precious Stones in the United States in 1914 amounted to $124,651, according to the Geological Survey. Of this, $60,932 was in sapphires; $13,370 in turquoise and matrix; $8,312 in agate, chalcedony, onyx, etc.; $7,980 in tourmaline; and the remainder of the production scattering.

The Second Pan-American Scientific Congress

On Oct. 23 the preliminary arrangements were completed for the most comprehensive international conference that has ever been held in the United States. From Dec. 27, 1915, to Jan. 8, 1916, there will meet in Washington, D. C., the Second Pan-American Scientific Congress, in which all of the American republics will participate and for which preparations have been going on for nearly two years.

According to the official reports, each of the 21 American republics will appoint delegations composed of its leading educators, economists, engineers, international lawyers, and experts on mining, agriculture, health, transportation and finance. From present indications it is estimated that there will be in attendance over 150 of the most representative men of Central and South America.

The first congress was held in Santiago, the capital of Chile, in 1908. That was attended by hundreds of the leading scientists of the Americas, including a large delegation from the United States. When it adjourned, it unanimously agreed to hold the second in Washington. The United States Government has therefore appropriated $50,000 for the expenses of the conference, and the President of the United States was authorized by Congress to invite all the other American governments to participate. The authority for the preliminary arrangements was placed in the hands of the Secretary of State, who in turn appointed an executive committee to make all preparations for the congress. This committee consists of:

William Phillips, Third Assistant Secretary of State and chairman ex-officio.

James Brown Scott, secretary of the Carnegie Endowment for International Peace, vice-chairman.

William H. Welch, president of National Academy of Sciences, honorary vice-chairman

John Barrett, director-general of the Pan-American Union and secretary-general of the committee.

W. H. Bixby, brigadier-general, U. S. A., retired.

Philander P. Claxton, Commissioner of Education.

William C. Gorgas, surgeon-general, U. S. A.

William H. Holmes, head curator of Smithsonian Institution.

Hennen Jennings, former president of London Institution of Mining and Metallurgy.

George M. Rommel, chief, Animal Husbandry Division, Bureau of Animal Industry, Department of Agriculture.

L. S. Rowe, president of American Academy of Political and Social Science.

Robert S. Woodward, president of Carnegie Institution, of Washington.

The president of the congress will be Eduardo Suárez-Mujica, Ambassador of Chile.

Motor-Truck Ore Hauling in California

Motor-truck freighting in competition with the railroad in southern California is reported as failing to be as successful as was anticipated. The men who engaged in motor-truck freighting in direct competition with the railroad are said to have created the impression that the steam and the electric railways would in a short time be supplanted as freight carriers by motor trucks. This is one of the wild dreams indulged by automobile manufacturers and drivers; but it is one of the most painful ones from which to awaken.

The motor truck has a place in southern California and especially on the desert and in the mining districts, not so much in competition as in connection with railroad freight transportation. The actual competition of the motor-truck freighter is with the mule and the horse. There are places, of course, where the automobile has difficulty in climbing the hills, but these places are few and good road construction would reduce them to an inconsiderable minimum. Automobiles are being used very extensively for carrying express and parcel post, not only in southern but in northern California as well; but comparatively little of this is in competition with the steam and the electric railway lines. In the heavy freighting by motor trucks there is practically no competition with railways, but in the suburbs and between the smaller towns, the automobile has made heavy inroads on the passenger traffic of the railroads, more particularly the steam railroad. So far as the motor stage is concerned, whose chief competition is with the horses and mules, the advancement or failure of this method of heavy transportation in the mining districts will depend upon the improvement of the automobile to meet the requirements of the desert and mountain roads. Large amounts of parcel-post and express matter, and in some instances articles of weight and bulk, are hauled in the small cars built for passenger purposes and not in any respect adapted to the carrying of even light freight.

The automobile manufacturers seem to have given more attention to the carrying of passengers in the mining districts than to the hauling of freight. There is a demand for light freight automobiles in various districts, in addition to practical passenger cars.

The Drills

By Berton Braley

Hear the clamor of the drills
As they bark,
As they batter the foundations
Of the everlasting hills
In the dimly lighted dark,
And the loud reverberations
Fill the murky stopes with sound,
Waking echoes underground!

Oh, there's music to the drills,
And it thrills,
For the clamor as they hammer
And they batter on the rock
Is a song of brave endeavor
And of hope and progress too.
For the drills are drilling ever,
Making dreams come true!

Hear the ringing, swinging measure
Of the drills
As they dig for buried treasure
Underneath the mighty hills;
How they shout in joyous mirth
In the caverns of the earth!

How they clatter as they shatter
All the locks that guard the ore,
And their song grows ever louder
As they bore, bore, bore,
Making ready for the powder [der
Which shall wrench the rocks asun-
With a sound of muffled thunder,
With a deep and mighty roar

In the deepest nooks and niches
Go the drills,
Reaching for the hidden riches
And the buried wealth that fills
Nature's treasure houses deep.
So the gold that misers heap,
And the silver and the lead
And the copper rich and red—
They are all the fruit of toiling
Of the drills;
They are plunder from the spoiling
Of the hills;

So the heart of man beats faster
And his every fiber thrills
To the song that makes him master
Of the treasure of the hills,
To the yammer and the hammer
And the wild barbaric clamor
And the unrelenting war song
Of the drills.

Cost of Mine Openings*

SYNOPSIS—The cost of opening ground for mining development has never been standardized, and there is a wide difference of opinion as to the real value of work intended to serve as assessment on claims. Facts and figures are given in this article, and standardizations made which may serve as a guide to similar work.

A large part of the early development work on most mining properties consists of surface excavations such as opencuts, trenches, shallow shafts and short tunnels. Of this work the greater portion may be classed as the annual labor performed on unpatented claims. This assessment work entails the expenditure of large sums each year throughout the mining regions of the West. Its unit cost of course varies greatly under the peculiar conditions applicable to particular localities. There is, however, a much greater difference in the cost of mining work in separated regions as depth is reached.

Costs for Excavations by Hand

During the last four years in the Northwest, in inspecting about $500,000 worth of surface prospect work, I have taken advantage of many opportunities to collect authentic cost data along this line. The figures given here are all for handwork. In the specific cases to which references are made an average efficiency of the labor was obtained. With a higher efficiency, undoubtedly much lower costs could be shown in some cases.

The performance of assessment work is not taken seriously by a great many people, particularly when the owner does the work himself, not with a view to the real development of the ground, but merely to hold it. In such cases it is only natural to expect that the amount of work will be stinted. Men usually apportion to themselves higher wages than they could obtain elsewhere, and in addition work short hours. Where owners hire the work done, no matter for what purpose the ground is held, they aim to get full value for the money expended.

There is a sort of tradition among many miners and claim owners that all assessment work is worth $10 per foot and that the United States Government will allow that valuation for the work when passing on claims for patent. This is not the case, however, as the law pertaining to the statutory expenditure on a claim is very specific as to the value of the work required, and no mention is made of feet or yardage. When a full $100 has not been expended as annual labor on an unpatented claim, it is subject to adverse location, no matter how many feet of work have been done. Accordingly, it behooves every owner of unpatented mining property to acquaint himself with the reasonable value of work performed upon his claims, so that he may be in a position to protect himself from a charge of abandonment for failure to do the requisite amount of assessment work.

Quite often among non-mining-claim owners, and even among some mining men, there is a misconception of the actual cost of surface mining work. A miner, on completing work on a mining claim, will generally report so many feet of tunnel run, or of shaft sunk, for a certain amount of money expended. To a man who has no way of knowing the cost of surface work, this reported cost may sound reasonable, but not to a man of experience in this line. As an instance: A miner, who had been hired by a claim owner to do the annual labor, reported a 10-ft. shaft sunk for the $100. The owner, who remembered reading mining companies' reports of shafts that cost from $40 to $150 per foot, considered he was receiving his money's worth; while, as a matter of fact, the miner should in this case have sunk four 10-ft. shafts for the $100.

Throughout the country great numbers of unpatented mining claims which show promise, and in which the owners have faith, are held by business and professional men who, in having the annual assessment work performed, want every dollar to count in the way of developing the ground. Usually, men are employed on a daily-wage basis to do this work, nearly always unsupervised. It is difficult to get full returns for the money thus paid for unsupervised labor, but a great many claim owners insist on getting fair returns and take steps to insure good results by making it clear to the miners that they are not going on a picnic, and by checking up the work as often as possible.

There is no doubt that, ordinarily, greater efficiency can be obtained from men working under direct supervision, as in a city trench, than working without it in some remote place. This does not, however, necessarily mean that the unit of a large operation carried on by fully supervised labor can be conducted more cheaply than can the small job performed by unsupervised workmen. This is attributable to the absence of all overhead and depreciation charges such as large contractors have to carry. Quite often, where only a few men are working, there is no overhead expense whatever to charge against the cost of the work.

Another thing to keep in mind is the correct number of men to be put on a job to get the best results. In this respect there are other things to consider besides the placing of the men with a view of working to the best advantage. A case has been brought to my attention where two men were sent out to a camp in the hills to do the annual labor on two lode claims. After the completion of the work on the first claim, a third man was sent out to help finish the job. In checking up the results, it was found that more work was done for the $100 on the first claim than on the second, under identical working conditions. The mystery was finally solved when it occurred to the owner that "slough" is a three-hand game.

Relation Between Wage Scale and Total Cost

Increased cost of work naturally results where higher wages are paid and the working day is shorter, but the resulting increase is seldom as much as the price per hour per man would appear to indicate. Men working an 8-hr. day will generally do a greater amount of work per hour than those working a 10-hr. day. It was noticed in places underground that when an 8-hr., instead of a 10-hr., schedule was put into effect practically the same amount of work was accomplished in the shorter shift.

*Read by E. D. Gardner before the Montana Society of Engineers, Butte, Mont., Apr. 10, 1913.

Better work may be expected, other conditions being equal, from miners in a $4 camp than from those in a $3 one. The mines paying the higher wages naturally have a larger number of men from which to choose their workers. As a rule, high-priced men are more efficient than those receiving smaller wages. As an example: On a rush job miners at $3.25 per 8-hr. day were put to work to help finish an excavation on which a Greek section crew were working at $1.75 per 10-hr. day. The cost per cubic yard of the work done by the miners was a little less than that done by the section crew. This is of course an exceptional case, and allowance must be made for cost per hour of labor.

Places where surface excavations are made are generally in the outskirts of the main districts or in places remote from centers of population, where it is necessary for the men either to go some distance to work or live at a camp. Generally, the more efficient men are not obtainable to do this work at the standard scale of wages for the locality. Such jobs are usually relatively short and have other obvious disadvantages, to offset which it is often customary to pay $0.25 or $0.50 per shift more than the standard scale.

It sometimes occurs, though seldom, that a shaft or tunnel is started at the surface where the rock is unaltered and may be as difficult to excavate as at depth. Ordinarily the work is in rock affected by weathering and decomposition. In most mining districts the sedimentary rocks are shattered and softer at the surface. The igneous rocks also have the same tendency toward disintegration, particularly in the vicinity of veins. Exposed rock is seldom as hard as that found at depth.

The Cubic-Yard Basis for Openwork

The simplest forms of development work are opencuts and trenches. Later, when the location of the lead is determined, shafts may be sunk or, if the contour of the ground is favorable, adits opened.

In computing costs, opencuts and trenches are calculated on a cubic-yard basis and shafts and tunnels by the linear foot, due allowance being made for the size of the cross-sections. A good method of arriving at the cost of shaft is to figure the first 7 ft. as an opencut on a cubic-yard basis, and from there down as a shaft at so much per foot in depth. Material can be readily thrown with a shovel from a depth of 7 ft. To do so from a greater depth increases the cost per cubic yard, and where a windlass is to be installed in any event, it is not economy. It is common practice in city trenches, and to some extent in shafts where no greater depth is desired, to throw material from a depth of 8 or 9 ft. to the surface. Shafts are often sunk to a depth of 15 ft. or more without installing a windlass, the material excavated being thrown to the surface by means of benches. The broken rock is thrown from the bottom to a bench and from there to the surface.

The cost per cubic yard of opencuts varies from $0.50 to several dollars; prospect tunnels, from $2.50 to $30 per ft.; and prospect shafts, from $4 to $40 per ft. depending upon the conditions. The cross-sections of such tunnels and shafts are generally 4x6 ft.

At Butte, with miners' wages $3.50 per 8-hr. shift, the cost of opencut work averages about $1 per cu.yd. The formation is a quartz monzonite, locally known as the Butte granite. This rock, with the exception of unaltered boulders and an occasional ledge of solid granite which outcrops, decomposes at the surface and to quite a depth in the proximity of veins. The boulders are mainly at the surface, but are frequently found below and in veins at depth. There is almost an entire absence of any angular slide overburden. At points where the granite is well disintegrated, the cost of opencut work will be less than $1 per cu.yd. On the other hand, where boulders are encountered and in ledges of solid granite the cost will be considerably higher. Excavations in this district are nearly always started in the decomposed granite. There is not much object in starting them in hard rock as no vein outcrops are found in the unaltered portions. The altered granite near the surface is mostly picking ground, and little blasting is required in openwork.

The cost of short tunnels from the surface at Butte runs from $3 to $8 per ft., except some work on the main range in hard aplite, which costs over $10 per ft. In the majority of cases involving decomposed granite, the cost is between $4 and $5 per ft. This includes cutting the timber standing on the claim or near-by and placing it in the tunnel, but not its purchase price or the expense of bringing it from a distance. Generally, where the rock is soft enough to require timbering, the greater ease with which it is broken will compensate for the extra labor of cutting timber and putting in sets. Where the tunnels run into spiling ground and into hard boulders, the cost will of course be increased. These figures do not refer to tunnels of large cross-section in the solid granite in the deep mines.

The cost per ft. of sinking prospect shafts in the Butte granite depends on the amount of decomposition of the rock and on the depth of the shaft. Prospect shafts are generally about 4 ft. wide and 6 ft. long, as this makes a convenient-sized excavation in which one man may work. The average cost of a 4x6 shaft 15 ft. deep is about $5 per foot below a depth of 7 ft., the upper 7 ft being figured on a yardage basis. The cost increases with depth. A 4x6-ft. shaft 10 ft. deep is generally considered by the United States mineral surveyors and others at Butte as costing $25. This is generally a fair valuation, but in some cases it is a little high.

Patent Work Done on Mining Claims

Patent work amounting to $25,000, done under the supervision of two men on about 50 scattered lode claims ranging from four to six miles from Butte, showed a cost of $0.80 to $1.25 per cu.yd. for opencut work and an average of $5 per ft. for tunnels. The work done on a single claim of this number for an expenditure of $500 aggregated 113 cu.yd. of opencuts and a partly timbered tunnel 3x6x84 ft. long. The cost of the tunnel, by allowing $1 per cu.yd. for the openwork, was $4.60 per linear foot. The work on all of the claims consisted of opencuts and tunnels with a few shafts. The deepest shaft was 55 ft., and the others were comparatively shallow. The cost of the deepest shaft to a depth of 47 ft. was $370, or nearly $8 per ft., and to the depth of 55 ft., $470, making the last 8 ft. cost $12.50 per ft. This shaft was sunk on a vein on a 45° incline, and was cribbed with an inside measurement of 3x5 ft. The broken rock was hoisted by a hand windlass in a bucket sliding up on guides. In this case the construction of the windlass and frame and other extra work made up for

the smaller cost of the first 7 ft. The formation was more or less decomposed Butte granite, and required blasting. From the last part of the shaft some water had to be bailed. It is considered that 55 ft. is just about the limit for economical sinking with a hand windlass.

Another shaft 4x6x15 ft. cost $48. This amounted to $1 per cubic yard for the first 7 ft., and a little over $5 per ft. for the remainder. The cost to the City of Butte of excavating the material in sewer trenches within the granite area amounted to $2.16 per cu.yd. The trenches were 2 ft. wide and averaged 9 ft. deep. All the work was done by contractors. Wages for ditch diggers are $4 per 8 hr. this being the minimum price for all laborers on city work, and is $0.50 per day more than is now paid to miners. This rate of wage has been fixed by ordinance of the city government. City contractors in Butte have to contend with numerous labor-union regulations. The higher cost per yard of this work than for opencut mining is due to the labor situation, the great depth and small width of the trenches, and the larger proportion of solid granite, consisting of boulders and ledges included in the softer material that has to be moved.

A 300-ft. tunnel run from the surface in a hard, compact granite cliff at the head of Rattlesnake Creek in Beaverhead County, cost $28 per ft. Several hundred feet of prospect tunnels on the porphyry dike in the Remini district, Montana, were run by contract for $3 per ft. Prospect tunnels in the soft porphyry in the lowlands district, Montana, cost from $2 to $5 per ft.

Tunnels in the soft schist in the Crevasse mining district, Montana, cost from $4 to $5 per ft.

Cost of Work in the Cœur d'Alenes

In the Cœur d'Alene mining district there are few outcrops and the surface on the mountainsides is generally covered with soil and angular wash to a depth of 2 to 8 or 10 ft. Under the overburden the formation in place nearly always is broken and shattered to an appreciable depth, but very seldom over 15 ft. or 20 ft. The formation is a series of sedimentary rocks which are, on the whole, easily eroded and weathered. There are a few hard strata, such as the copper beds in the Revette quartzite, which resist weathering and are as hard at the surface as at depth, but these comprise only a very small part of the whole series. Miners' wages are $3.50 for 8 hr. The cost of surface cuts here is found to be a little higher than at Butte, averaging about $1.20 per cu.yd. for the material removed. Individual cuts cost from $0.75 per cu.yd. when in wash, to $2 per cu.yd. when in the harder rock. The average cost of a series of cuts up to 7 ft. in depth on flat surfaces and with 12-ft. faces on side-hills, was $1.20 per cu.yd. In classifying the material most of the rock in place in opencut work would come under the head of loose rock.

The average rock in the Cœur d'Alenes is much softer than the solid granite at Butte, but harder than the altered granite. The cost of prospect tunnels in the Cœur d'Alenes ranges from $3.50 to $10 per ft., according to the hardness of the rock, with an average of about $6. The contract price of a tunnel in the shale above Pottsville, Ida., from 400 to 500 ft. from the portal, was $4.50 per ft. The total cost to the contractor, however, was $3.50 per ft. Surface prospect tunnels run by one of the mining companies in hard quartzite at Burke, Ida., cost $10 per ft.

Annual assessment work on five lime placer claims 12 mi. from the railroad on Pend d'Oreille River, in Washington, showed an average cost of $3.23 per cu.yd. of rock removed. Wages were $3.50 for 9 hr. The formation was tough, compact limestone and dolomite, with an entire absence of all surface weathering and overburden. The cuts were made in the bluffs above the river.

Development Expense in Washington

Development work in opencuts on lime placer claims at Metaline Falls, Wash., in solid limestone, cost from $2.50 to $4.10 per cu.yd. The cost per cubic yard of opencuts on a vein in disintegrated andesite on the north half of the Colville Indian Reservation, Washington, was $0.94 per cu.yd. The cuts averaged 34 ft. long, with 15-ft. faces. Wages $3.50 for 9 hr. The contract price for excavating solid rock in trenches 3x9 ft. deep in the City of Spokane, Wash., was $4.75 per cu.yd. This rock is a basalt of extreme toughness and requires an excessive amount of drilling and blasting. The contract price for the same work in opencuts in street work was from $0.90 to $1.25 per cu.yd. The cost to the city for removing gravel in the same-sized trenches was $0.90 to $1 per cu.yd. Wages are $3 for 8 hr. for city work. The contractors figure that 20% of the cost consists of overhead charges, interest and depreciation and 6% tax for workmen's compensation.

Opencuts made at Bingham, Utah, in weathered limestone and quartzite and slide rock, under my direction, cost $0.80 per cu.yd. Prospect tunnels in the same formation cost $4 to $6 per ft. Miners' wages were $3.25 for 8 hr. Hand placer work is cheaper, on the whole, than the same kind of work on the lode claims, which is to be expected from the nature of the material handled in each case. The formation of placers consists of stream gravel, sand or clay, with an occasional boulder, and in some cases cemented strata. Hand placer excavating is straight pick-and-shovel work except where boulders are encountered. In hand sinking on many placer properties the amount of water that has to be bailed or pumped out is the greatest factor in determining the cost, and often the quantity of water entirely prevents sinking. In many places cemented strata are entirely absent and what boulders are found are near bedrock and need not be moved in prospect work.

By considering how much gravel a man can handle per shift and his daily wage, it would be possible theoretically to arrive at the cost of most placer excavations. Byrne, on page 202 of his Inspector's Hand Book, gives the average amount of material a man can loosen per hour with a pick as, in clay or cemented gravel, 1 yd.; loam or loose gravel, 2 to 3 yd.; sand, 4 to 6 yd. On the same page he gives the average quantity a man can shovel per hour with a limit to the cast of 6 ft. vertically and 12 ft. horizontally as in rock, 1 yd.; clay or heavy soils, 1.5 yd.; loose earth or sand, 2 yd.

By taking Byrne's figures of 2½ yd. per hr. for loosening gravel and of 1.5 yd. per hr. for shoveling, a man in an 8-hr. shift could excavate a trifle over 8 cu.yd. of material. By allowing for miners $3.50 per 8 hr., the cost per yard would be $0.44. This agrees fairly well with other authorities, such as Gillette and Trautwine.

On placers, the cost of openwork or trenches up to 7 ft. deep with little or no water varies from $0.40 to $1 per cu.yd., depending on the nature of the material and the price of labor. Timbered prospect tunnels in gravel cost generally from $4 to $6 per linear foot. The cost of a 10 ft. shaft with little or no water is generally taken as being $10. Frozen gravel is not taken into consideration.

Trenches in city streets, particularly in a mountainous country, are quite often in material similar to that found on placers. Costs are generally kept fairly close on this work and can be used as a basis of comparison for placer work in similar ground.

At Missoula, Mont., it costs the Missoula Light and Water Co. an average of $0.36 per cubic yard to do the excavating for city water trenches 2x6 ft. The work is done by day labor, with wages at $3 for 8 hr. The material moved is almost entirely wash gravel, with an occasional hardpan.

The Great Falls Water Co., at Great Falls, Mont., in excavating for city water pipes moved 89% earth, 5% solid rock and 6% loose rock at an average cost of $0.34 per cu.yd. Wages were $2.25 for 10 hr. S. Lefevre, in his article in the February "Bulletin" of the American Institute of Mining Engineers gives the cost of surface excavations at Mineville, N. Y., in hardpan and boulders, as $0.80 to $1 per cu.yd. Wages for this kind of work are about $2 per 10 hr. Well diggers sink 5x5-ft. wells up to 30 ft. in depth on the Missoula Flat, at Missoula, Mont., on contract, at $1.50 per ft. including placing but not supplying the timber. Below 30 ft. the cost increases. The Flat is an old river bottom, and consists mostly of river gravel.

*

The Boulder Batholith

BUTTE CORRESPONDENCE

The Boulder batholith and its bearing upon the future of mining in the entire district was the subject of consideration and discussion at a meeting and banquet of the Montana section of the Institute of Mining Engineers in Butte, Oct. 8. The subject was presented by J. A. Grimes and was a continuation of the discussion on a paper prepared jointly by Mr. Grimes and Paul Billingsley and read at a previous meeting of the Montana section.

The Boulder batholith includes the granite formations that compose the mining district that centers around Butte. It extends from the Bannack mining district in southwestern Montana north to the Marysville district north of Helena and from the mining districts around Phillipsburg in Granite County on the west to and including the Radersburg district on the east.

This district ranks today, he said, as one of the greatest metal-producing sections, if not the greatest, in the world. From a special study, which took in 70 distinct mining districts in which are located over 700 mines that are either producing at present or have been producers at some period of their history, it is shown that the granite formation of the Boulder batholith bears a regularly defined mineral enrichment. The gold is found in the strata just above the granite formation in some districts, like that of Marysville in particular. The silver ores are found generally just on the upper edge of the granite. The silver-lead ores are found just below the upper edge, while the zinc ores are found at a somewhat deeper level. Below the zinc comes the copper formation, although this, outside of certain exceptional districts such as Butte, is of such low grade as not to be commercial ore. Going lower, they run into the iron-bearing quartz, and the indication is that the mineralized section does not run deeper than that.

Mr. Grimes noted four exceptions in particular to the rules that apply in the rest of the district covered by the Boulder batholith. These exceptions are the Hecla mine, the Granite-Bimetallic, the Elkhorn and the Butte districts. In the last, a depth of 3,400 ft. has not yet taken the explorations to the bottom of the copper-bearing ores, and in the Elkhorn district the end has not been reached at a depth of 2,100 ft.

*

The Gennamari Mill, Sardinia

BY C. W. WRIGHT*

The problem of remodeling the Gennamari mill, to be described, was a simple one because of the character of the ores treated. The object of the change was to increase the metal recovery and to reduce milling costs and thus permit the treating of lower-grade ores at a profit.

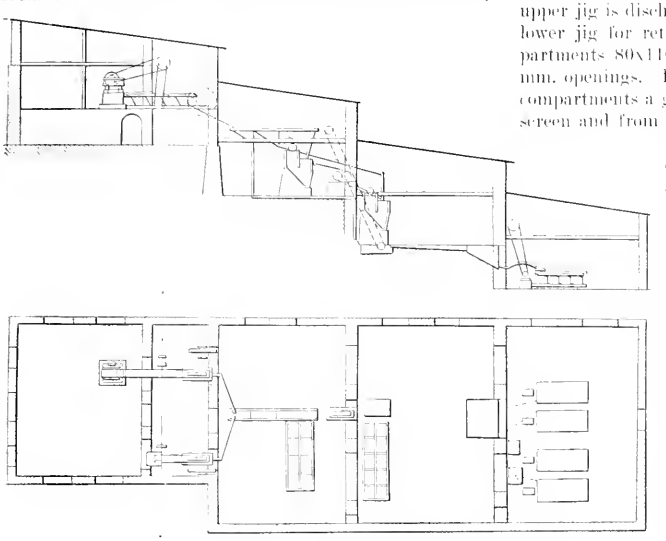
A series of careful tests at this mill in 1910, extending over several months, showed a metal recovery of only 60%, two-thirds of the loss being in the fines under 1½ mm. in size, all of which material was treated in a few small jigs. These tests showed the immediate need of tables for the treatment of the fine ore, which was being carried down the river and lost. Tables were designed and built at the mine, and eight were installed along with necessary classifiers and dewatering boxes. The metal recovery was gradually increased to 75%, which was largely due to the tables, though the costs were still high. The next change was to replace the small-sized Harz jigs, treating ½ ton per hr., with large jigs similar in type but of 6 tons or more capacity per hr., and to eliminate the system of close sizing. By these alterations, which are described in detail, the lead recovery was further increased to 80% and the costs of milling were reduced. Finally, last year, a plant for the retreatment of the slimes was built, using large spitzkasten, 3 slime tables and 2 corrugated rubber-belt vanners. This last improvement has increased the lead recovery to 86%.

DESCRIPTION OF THE GENNAMARI ORES

At the Gennamari mine the ore is galena, which occurs in fissure veins traversing both the granite and schist country rock. The veins in the granite contain quartz and siderite in about equal proportions as gangue minerals, while those in the schist have siderite, blende, pyrite, some calcite and quartz as gangue minerals. The veins average about 6% lead; the galena is in compact veinlets and pieces and not minutely disseminated, so that its separation is fairly simple. The coarse lumps of lead ore are sorted by hand in the stopes and on the *piazzales*, while the rest of the ore which averages from 3 to 4% in lead is transported to the mill. The material from the stopes, which yield a low-grade ore, is sent direct to the mill after a sorting out of the larger waste rock, which is left as filling.

*Mining engineer, Ingurtosu, Sardinia, Italy.

At the mill are bins of 250 tons' capacity equipped with grizzlies having 30-mm. openings to separate the coarse ore, which is delivered in cars along the side of the crushers and fed into them by shovel. The fine ore, which passes through the grizzly, is delivered into a small bin equipped with an automatic feeder. Both the ore from the crusher and the fine ore are fed to shaking



SECTION OF PART OF THE GENNAMARI MILL, SARDINIA

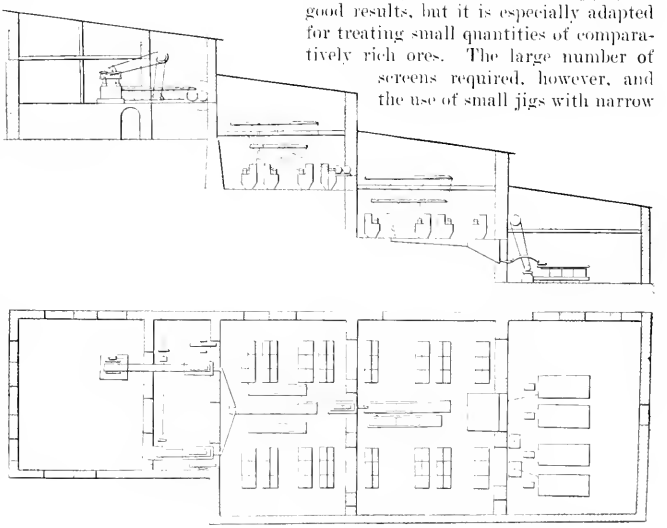
screens with 15-mm. openings. The oversize goes to a set of rolls at the end of the screen, and the undersize goes direct to the screen below the rolls for further sizing. The opening between the rolls is set at about 10 mm., and they are kept in constant adjustment so that there is practically no oversize from the screens.

The main modifications in the mill begin at this point. They consist of a reduction in the sizing of the ores, thus requiring fewer screens and the use of larger jigs. Four of the shaking jigs have been abolished, and 14 small jigs have been replaced with two large ones. One section of the mill was first modified, and after six months of comparative tests the second mill section was also changed. A plan and elevation of both the old and new sections have been added and these show clearly the changes that have been made in the treatment methods.

The amount of ore treated is from 9 to 10 tons per hr. in each section. After the ore has been crushed, it is graded into 3 sizes, 0 to 1, 1 to 4, and 4 to 15 mm. The fine size, which amounts to about 15% of the feed, goes to the spitzkasten and on to tables for treatment. The size from 1 to 4 mm. goes to a lower jig, and the size 4 to 15 mm. is sent to the upper jig. The upper jig has four compartments 90 by 120 cm. in size. From the first compartment a galena product is made on the jig screen, having 5-mm. openings, and in the hutch. From the other three compartments a middling is drawn off above the jig screens through the pipe discharges and sent to a set of rolls to be reground, after which it goes to the lower jig. The hutch product from the last three compartments of the upper jig is discharged into a canal and sent direct to the lower jig for retreatment. The lower jig has five compartments 80X110 cm. in size, the jig screens having 3-mm. openings. From the first and sometimes the second compartments a galena product is obtained both from the screen and from the hutch. The middling product from the jig screen and the hutch of the other compartments is delivered to an elevator and is either sent to a set of regrinding rolls and returned to the lower jig for treatment or sent to a ball mill and treated separately.

The upper jig receives about 45 tons per shift and makes 24 tons of tailings containing traces of lead, 20 tons of middlings with 5% lead, and about 1,000 kg. of galena containing 55% lead. The lower jig receives 20 tons of direct feed from 1 to 4 mm. in size and 20 tons of recrushed middlings from the upper jig. This jig makes 35 tons of tailings with traces of lead, 14 tons of middlings with 5% lead and 1 ton of product containing 65% lead. The mill is only operated one shift of ten hours a day.

The old system of using small jigs gave good results, but it is especially adapted for treating small quantities of comparatively rich ores. The large number of screens required, however, and the use of small jigs with narrow



ANOTHER PART OF THE GENNAMARI MILL, SARDINIA

compartments and screen areas naturally increase the cost of attendance, repairs and water consumption and make this method impractical for the treatment of a large tonnage of low-grade ore.

The following tables are added to show some of the advantages of the new method over the old one. As the

difference in the two systems is confined to the modifications in the screening and jig treatment, only these changes will be considered.

Comparison of Machines in Operation

Old Section		New Section	
Shaking screens, upper floor	3	Shaking screens	1
Jigs for coarse ore	6	Jig for coarse ore	1
Shaking screens, lower floor	2	Jig for fine ore	1
Jigs for fine ore	8	Elevator	1
Total number of machines	19	Total number of machines	4
Cost of machinery, lire	20,000	Cost of machinery, lire	10,000

Reduction in Power Consumption (Although Amount not Determined)

Water consumption per min., liters	1,080	Water consumption per min., liters	380
Area of jig screens, sq. m	175	Area of jig screens, sq. m	85
Labor		Labor	
Screens	1	Upper jig	1
Upper jigs	3	Lower jig	1
Lower jigs	4	Screen, etc.	1
Total	8	Total	3

Cost of Supplies and Repairs (Oil, Belting, New Screens, Etc)

Screening, lire	224 53	Screening, lire	96 65
Jigging, lire	169 68	Jigging, lire	76 30
Transmission, lire	124.45	Transmission, lire	79 30
Total, lire	518 66	Total, lire	252.94

Besides the advantages mentioned, the new system permits a more accurate supervision of the jigs, with the result that more uniform products are obtained.

Antimony Mining in Bolivia

Antimony mining in Bolivia has recently been active, according to a correspondent of the London *Mining Journal*, who writes as follows:

As regards antimony, 1,315 tons were exported during the first five months of this year, as compared with 120 tons during the same period of last year. The high prices had already stimulated production, and since then there has been great activity. Antimony is quite widely distributed throughout the metamorphic slates of the Bolivian plateaus. The veins are not usually constant, but frequently form quite large pockets. So far there is practically no development work, and the ore being mined is superficial; still it is almost entirely sulphide of good quality, with little or no lead. No capital has been invested in antimony mining; work is from hand to mouth, and there are no reserves blocked out which might give an idea of the permanency of the deposits, but these are so numerous that with good prices there is no doubt that the output will be considerable. I have not any sure data to go on, but I think that at least 1,000 tons of antimony ore of over 60% is leaving the country monthly at the present time. Of course local conditions of scarcity of labor and means of transport soon limit output, and it is to a large extent at the expense of the tin mines that antimony is being produced; although, on account of the antimony deposits being at a lower altitude, part of the workmen employed on them are of a class that does not go up to the large mines.

The ore is spalled by hand, and naturally a good deal of lower-grade stuff remains in the dumps, as well as a considerable proportion of zinc, which by concentration would yield a good marketable product.

The high transport costs practically prohibit antimony mining in Bolivia except when prices are abnormally inflated, and therefore a stable industry cannot be counted on, the natural consequence being that no money is forthcoming for the development of the antimony industry.

Many commercial houses have been buying and exporting antimony, among them Gibbs & Co., which, I am told, has been doing so for the English Government.

Employees' Liens in California

By A. L. H. Street*

An owner of a California mine will not be subjected to a lien for compensation due an employee employed by one known by the latter to be operating the mine under an option to purchase the property, according to the holding of the California District Court of Appeal in the late case of Street vs. Hazzard, 149 *Pacific Reporter*, 770.

*Attorney at law, Minneapolis, Minn.

Another point decided in the same case is that the failure of the owner of mining property to file for record, as required by the California statutes, a notice disclaiming liability for work done on the property, does not give a lien to a workman who had actual notice of the fact that the owner was not his employer.

Volunteer Engineer Officers

In view of the program, which has been made public, of the Administration's plans for preparedness with particular reference to increases in the army, the following from General Orders No. 54, 1914, and General Orders No. 50, 1915, War Department, Washington, D. C., will be of interest.

For the purpose of securing a list of persons specially qualified to hold commissions in any volunteer force which may be called for and organized under the authority of Congress, other than a force composed of the organized militia, the Secretary of War is authorized from time to time to convene boards of officers at suitable and convenient army posts in different parts of the United States, who shall examine, as to their qualifications for the command of troops or for the performance of staff duties, all applicants who, being citizens of the United States, come within the prescribed limitations.

For engineers these requirements are, besides passing a satisfactory physical and moral examination and the presenting to the board of evidence of their technical qualifications together with a full statement of their professional experience,

3. For the grades of lieutenant—(a) The candidate must be an engineer in the active practice of his profession or in some business immediately connected with or concerned in engineering matters.

(b) He must either hold the grade of junior engineer, civil, electrical or mechanical, or higher grade in the civil service, or he must be a graduate from an approved engineering college, or belong to one of the following national engineering societies in a grade not lower than that shown opposite to each: The American Society of Civil Engineers—junior member; the American Institute of Mining Engineers—member; the American Society of Mechanical Engineers—junior; the American Institute of Electrical Engineers—associate. Or he must be or have been a noncommissioned officer of the grade of sergeant or above from one of the regular battalions of engineers.

4. For the grade of captain—(a) Same as 3 (a).

(b) He must either hold the grade of assistant engineer in the Engineer Department at Large or a corresponding engineer grade in the civil service in another department of the Government service, or be an associate member, or member of one of the national engineering societies enumerated under 3 (b), or have held a commission in the Corps of Engineers of the regular army.

(c) Sufficient knowledge of Field Service Regulations, Army Regulations, and Tables of Organization to understand the type of information of which these regulations are the source.

5. For the grade of field officer—(a) Same as 3 (a).

(b) He must either hold the grade of assistant engineer in the Engineer Department at Large or a corresponding engineer grade under the civil service in another department of the Government service, or be a member of one of the first three national engineering societies enumerated in 3 (b), or be a fellow of the American Institute of Electrical Engineers, or have held a commission in the Corps of Engineers of the regular army not more than two grades below that for which he desires to be listed.

(c) In addition to fulfilling the qualifications given in 5 (a) and (b), the candidate will be required to pass the examination prescribed herein for a field officer of infantry and an examination on the duties of engineer officers and troops in war, what they are and how they are performed.

Applications for examination, accompanied by recommendations and other documents of a commendatory character (as prescribed in General Orders 54), should

be made to the adjutant-general of the state, according to the legal residence of the applicant, in the month of May or November, to the end that the governor of the state may forward the accumulated applications with his recommendations in each case, to the adjutant-general of the army about Jan. 1 and July 1 of each year.

Mining in Boulder County, Colo.

Special Correspondence

Boulder County, Colo., measuring 24 mi. north-south and approximately 32 mi. east-west, has unusually varied industries, due to the remarkable diversity in altitude, climate, geology and mineralization. Beginning at the eastern border there is a beautiful agricultural country with abundant irrigation and sustaining a thriving population. This area is underlain by splendid beds of lignite that have for years been extensively worked. The principal coal-mining towns are Lafayette, Mitchell, Superior, Louisville and Marshall. The surface of this coal-mining and farming area is a gently rolling prairie with an average altitude of about 5,000 ft.

Boulder, the county seat, lies immediately west of this farming and coal-mining area, where the plains and the foothills of the Rocky Mountains meet at an altitude of about 5,400 ft. Adjacent to the city—in fact, within it—the sedimentaries in the region to the east (where they lie practically flat) are tilted on edge, flanking great hills of metamorphic rock. In these steep beds may be found sandstones, limestones, shales and all sorts of clays. These rocks have been quarried for commercial uses, and the clays have been extensively used in the manufacture of bricks and refractory goods.

Metal Mines Situated in the Hilly Country

It is in the hilly country to the west of the city that we find the metal mines. Gold mining began here in 1859—almost contemporaneously with its beginning in the contiguous little county of Gilpin—and records show that the first location document ever filed in this state (then territory) was for a quartz vein not far from the city. Westwardly the hills rise back of one another to the crest of the continent, the county line, along which the average altitude is about 13,000 ft. Long's Peak, with an altitude of 14,271 ft., is in the very northwest corner of the county, while Arapahoe Peak, 13,176 ft. high, is about 22 mi. due west of Boulder. The station of Corona, remembered by all travelers over the Denver & Salt Lake (Moffat) Railroad, is in the southwest corner of this county.

The prevailing rocks of the mountainous country are granite, gneiss and schist, inclosing many strong dikes and sheets of siliceous porphyries. This is a region of typical vein fissuring. The veins vary in thickness up to 30 ft. or more and are inclosed by all the country rocks. They carry shoots or bodies valuable for their content of gold, silver, tungsten, lead and copper, all of which metals have been sought and mined commercially. Up to the present time little attention has been given to zinc, bismuth, vanadium and molybdenum, although these metals are known to occur here. They will unquestionably come in for recognition before long.

The veins that bear gold and silver are usually of complex character carrying sulphides of lead, iron, and copper in addition to the precious metals. The gangue is usually quartz. The ores of the two precious metals generally contain both silver and gold, but the variations in the relative amounts of these metals are such that some mines are classed as gold mines while others (sometimes contiguous properties) are considered silver mines. For instance, near the town of Crisman, the Yellow Pine mine has made a large production of silver that was accompanied by but a trace of gold; while the Logan mine, next to it, has a production record of about $150,000 in gold. The White Raven mine, near Ward, ships high-grade silver ore containing little or no gold. In the '70s the Caribou mine was said to be the greatest silver mine in Colorado, but it lies in proximity to other mines in which the chief metal is gold. As a general statement, however, it may be said that the majority of the metal mines in this county produce ores in which the principal value is the gold content.

Gold occurs free in the upper zones of the veins, and amalgamation was the common treatment during pioneer times. Below the zone of oxidation, the gold often exists in the telluride form, sylvanite, and cannot be saved by amalgamation. Formerly the stream beds were washed by primitive placer methods and unrecorded quantities of coarse gold recovered. Silver occurs in the native state and as the sulphide, argentite. Very often its presence in ore is not discernible because it is so fine and in such intimate association with lead and copper sulphides.

Tungsten Mining Becoming an Important Industry

Tungsten occurs in a narrow belt crossing the mountains in a northeasterly direction. The veins are found where granite and schist are crossed by pegmatite dikes that appear to possess a direct relationship to the mineralization. These tungsten veins are usually richer when they have walls of granite. The gangue most closely associated with these occurrences of tungsten is hornstone or cherty quartz. The tungsten, itself, occurs as ferberite, the tungstate of iron, and as hübnerite, the tungstate of manganese. The main production has been of the former, a black, heavy mineral that predominates in the southern portion of the field, where most of the development has taken place.

Tungsten mining in this county has been contemporaneous with tungsten mining throughout the United States. It began in 1900, when shipments amounted to about 40 tons of equivalent 60% WO_3 concentrates. The largest production was in 1910, when it was equivalent to 1,221 tons of this material. Altogether, up to the present time, statistics show that the county has furnished about 60% of the nation's production. With the recent remarkable strength in the tungsten-metal market there has been a pronounced increase in mining and prospecting for the metal, and the 1915 production will reach record figures for both tonnage and value. The Conger mine is the greatest tungsten mine in the world, its production having a gross value of nearly $1,500,000.

Practically all the tungsten production to date has been in a small territory at the southwesterly end of the belt, near the town of Nederland. The metal was known to occur in other parts of the county, but it has been only within the past few weeks that miners have given serious effort to developing it outside of the limited area. Now tungsten has been proved in paying quantities

several miles northeast of Nederland, at the camps of Magnolia, Sunshine, Salina and Wall Street.

The metal-mining part of the county—containing, along its westerly rim, glaciers and perpetual banks of snow—is well supplied with streams that provide water for milling purposes. These mountains, below timber line, were formerly heavily wooded, and even yet in places there are fine stands of pine. The Colorado Power Co.'s 20,000-hp. hydro-electric plant at Magnolia is in this mining country, and its transmission lines traverse the various districts. Water for this power generation is impounded by a great dam in Middle Boulder Creek, is conducted 12 mi. through a 35-in. reinforced-concrete pipe line under gravity flow to a small reservoir at the top of a steep mountain, down whose slope a steel 48-in. pipe line carries the water 9,400 ft. to turbines, where it enters under a head of 1,830 ft. Moderate rates for current consumption have been established. The county is crossed by the Colorado & Southern, Union Pacific, Burlington, Denver & Interurban, Denver, Boulder & Western and the Moffat railroads. Of these, only the last two penetrate the metal-mining parts. The Denver, Boulder & Western, frequently spoken of as the "Switzerland Trail," is narrow-gage and reaches most of the metal-mining camps.

Pioneer miners divided the metal-mining part of the county into eight so-called mining districts, known as Gold Hill, Central, Ward, Grand Island, Sugar Loaf, Magnolia, Boulder and Snowy Range. Necessarily, these districts are comparatively small, since the entire metal mining area is not over 15 mi. square. The Gold Hill district was the first organized in Colorado, and it also contained the first stamp mill, machinery for which was hauled by ox teams from St. Joseph, Mo.

Manifest Advantages Led to Unscrupulous Speculation

Because of its easy accessibility, its splendid climate and its actual mineral production, this county years ago fell a victim to practices of unscrupulous or inexperienced mine promoters who, securing options to attractively situated claims, incorporated companies and sold stock broadcast, little or no actual mining resulting from such financiering. Often, the capital raised by sales of stock was foolishly expended in the premature erection of showy milling plants. Perhaps some of these defunct concerns never had any sound bases for mining operations, but probably the majority of them might have succeeded had they been managed by mining men instead of sharpers.

Some Boulder County mining enterprises met their doom when, after legitimately and successfully operating for a long time on their oxidized ores, they encountered the sulphide and telluride ores that were distinctly refractory to the simple milling methods of a decade ago. Such companies were obliged to discontinue operations or to entirely reconstruct their plants and revise operations. Such crises occurred about the time of general national financial depression and the propagation, by magazines of large circulation, of the theory of the unsoundness of mining investments; with the result that the metal-mining industry of Boulder County has languished, or at least stood still, for years.

There is now, however, a decided revival of interest. Old mines are being reopened, new prospects are being exploited, and milling plants are being installed to treat ores by modern methods. A few operators are giving attention to the mining and treatment of low-grade ores, such as were avoided in the past. Because Boulder County projects have failed in numerous instances, the region is, by some, accused of being "pockety" in the sense that oreshoots are of trifling extent and that profits derived in mining some rich bodies are absorbed in developing new ones. This is not a wholly just charge. It is no more applicable to veins in this county than to those of any other typical vein district. Reference to a map will show that Boulder County is really part of the general mining area covering also Gilpin and Clear Creek Counties to the south. The veins of western Boulder County are, in fact, identical in their characteristics with those of Gilpin County. Nor is the latter county active, but nobody that knows this famous little district will say that its veins are defective or worked out, or that the ore occurs in small and widely spaced pockets. Analysis of the depression in mining activity in this region will show that it can be explained by reasons that are quite apart from natural deficiencies. Among such reasons are the lack of local plants for treating the sulphide ores, failure to accept and adopt new methods, erection of mills with capital that should have been used in development, unsystematic and illogical systems followed in mining, almost complete nonemployment of trained engineers or metallurgists, management of enterprises by wholly inexperienced persons, and the failure on the part of Boulder County residents in the past to oppose illegitimate schemes.

But a new order of things will hereafter prevail, and mining activities will be guided by men of experience. An encouraging thing is the experimentation or research that is being carried on by experienced millmen and metallurgists. Cyanidation and flotation are being adopted in some instances. It is hoped that future mining operations will not be managed by needy relatives of Eastern investors or by men whose only mining experiences have been in small districts like this one, in which economics has never been a serious study.

Social Improvement at Lead

Special Correspondence

A survey of conditions in a Western metal-mining camp from the viewpoint of a sociologist is always interesting to many classes of people. There is no denying that many employers have rather derided efforts toward social betterment and regarded them as a weakness on the part of their fellows who indulged in them, and failed to consider the increased efficiency obtained through better moral and social conditions. Our great industrial leaders have now changed their attitude and are giving serious consideration to the results of the work done in the field of social welfare.

Among the places under scrutiny is the little city of Lead, S. D. This municipality of 9,000 people is the abode of the Homestake property, classed as one of the world's greatest gold mines. Lead was one of the places visited by the Congressional Commission on Industrial Relations which investigated its first and only labor difficulty in 35 years of operation. Professor Commons, who displayed much interest in Lead, pronounced it the most remarkable and interesting community he had observed. From the fact that only one clash had occurred between the owners and their employees and the additional fact

that at least half of the men sided with the company in that trouble, one would correctly infer that much effort had been made to keep the miners satisfied with the working conditions and to maintain harmonious relations and comfortable living conditions.

Both the late superintendent, Thomas J. Grier, and the present incumbent, Richard Blackstone, entered the service of the Homestake Mining Co. shortly after its organization and consequently were closely identified with every movement inaugurated to preserve harmonious relations with the workmen. Both displayed interest in the social life of the men and may be properly classed among the men of business who first saw practical benefit through better social and living conditions.

One of the results of this interest is what is known as the recreation building. This was erected at a cost of $350,000 by the Homestake Mining Co. for the free use of its employees and the people of Lead. It contains the finest theater in the state, a magnificent swimming pool and rooms equipped for all forms of indoor recreation. Here is installed the famous Hearst Free Library, equipped and maintained by Mrs. Phoebe Hearst. The building forms an important part of the social life of the community and is a strong link in the chain of common interest between employer and workman.

The free medical and hospital service for all employees and their families; the Aid Association, which provides insurance at a minimum cost against sickness, accident and death; the auxiliary, a woman's organization to care for any cases of temporary destitution or need; and the liberal financial assistance to churches—these are among the measures that were inaugurated and fostered under the direction of the former and present managers. These things could not, of course, come in any other way than by gradual growth. During the reign, so-called, of the Western Federation of Miners many of the men took a position in opposition to everything proposed by the company and preferred to provide their own relief measures through their own organizations. Likewise the amusements and forms of social recreation were those supplied by people who collected a profit from them.

During the transition period following the fall of the Federation, the influence of the employers was predominant and there were suggested and placed in operation many measures which at other times might have been difficult to explain, both to directors and to employees. The pressing needs of the hour in caring for perhaps fifteen hundred new employees and their families permitted the easy introduction of better forms of entertainment as well as better sanitation and advanced safety methods. Once inaugurated, the ideas grew and developed with little notice or adverse comment. Measures to secure a home for each family desiring to own one were provided.

"Safety-First" methods, which would have been derided in the old days, were taken up with enthusiasm, and the eager desire for increased efficiency enabled a first-aid team of but a single year's existence to win the first prize at the Panama-Pacific Exposition in competition with the oldest and best teams in the country.

Figures showing a comparison between the number of accidents to employees under the old and the new methods and those showing the improvement in the number of hospital cases and serious cases of sickness are startling and offer in themselves a sufficient excuse for every advanced measure inaugurated.

Chronology of Mining for October, 1915

Oct. 3—Arizona militia ordered to Clifton on account of strike disorders.—Crushing begun in mill of United States Gold Co., Boulder, Colo.

Oct. 6—Operations resumed at Butte-Alex Scott.

Oct. 9—Derry Ranch dredge near Leadville, Colo., went into commission.

Oct. 10—Shafthouse and equipment of Matchless mine, Leadville, destroyed by fire.

Oct. 11—Commencement of suit of Elm Orlu vs. Butte & Superior.

Oct. 13—Pilares mine of Moctezuma Copper Co. and the concentrator at Nacozari, Sonora, closed down.

Oct. 14—Production of electrolytic zinc begun at Anaconda, Mont.

Oct. 16—New stamp mill of Brunswick Consolidated started.

Oct. 18—Stockholders of Tennessee Copper Co. approved the issue of $3,000,000 first-mortgage 10-year convertible 6% bonds.

Oct. 19—Carranza government in Mexico recognized by the United States.—Explosion of dynamite at Granite Mountain mine, Butte, Mont., 14 men killed.—Viloro dredge No. 2, Oroville, Calif., burned and sank.—Plant of Mineral Products Co., Marysvale, Utah, started operation.

Oct. 21—First spelter made at Donora, Penn.

Oct. 23—Stockholders of Southern Aluminium Co. voted to dissolve the corporation.

Oct. 25—Operations suspended at Cananea owing to cutting of railway by Yaquis.

Oct. 26—Beginning of strike at Silver King Coalition mine, Park City, Utah.

⁂

Japanese Phosphate Trade

Owing to the European war, Japanese imports of phosphate rock have been greatly interfered with. Florida phosphate is generally used by the fertilizer manufacturers of Japan, and in ordinary times costs about $7.25 per ton, while at present the freight rate alone is about $13.75, which, being added to the original cost of the phosphate, comes to about $20 per ton. Under these circumstances, efforts are being made to supply the Japanese companies with domestic products.

The Japan Phosphate Co. of Tokyo contemplates working its mine on a large scale, while the Rassa Island Phosphate Co., which has the biggest phosphate mines in Japan and which produces ordinarily about 50,000 tons per year, is said to be making preparations for a greatly enlarged production. The Japanese phosphate is said to contain a large percentage of iron, alumina, etc., and consequently is reputed to be a poor material for the manufacture of superphosphate, but under present conditions the Japanese enterprises may prove profitable.

⁂

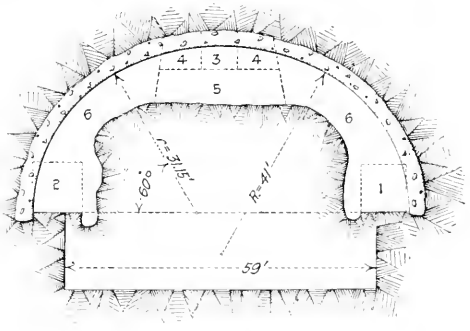
The Production of Nitrogen Compounds in Germany, particularly sulphate of ammonia and cyanamide, has been considerably increased during the course of the war, and the sale price of nitrate is said to have been lower than the cheapest price of the last 10 years, according to the "Journal of the Society of Chemical Industry," Sept. 30, 1915. In order that on the conclusion of peace the newly developed German industry may not be confronted with destructive foreign competition a national monopoly is now being considered.

Details of Practical Mining

The World's Largest Tunnel

The largest tunnel ever undertaken is that which has been partly driven at Marseilles, France, for the Marseilles-Rhône Canal for use as a barge-canal tunnel. The work was suspended at the outbreak of the war and the date of resumption is of course problematical. The tunnel, lined throughout, is nearly 4½ mi. (7.2 km.), is 22 m. (72.2 ft.) wide inside the lining, and the crown of the arch (nearly semicircular) is 9.90 m. (32½ ft.) high. The depth of water is to be 3 m. (10 ft.).

Excavation was begun by driving at the right a heading with a cross-section of 75 sq.ft., with its base at the elevation of the towpath. A second heading, of 96-sq.ft. section, was driven at the same elevation on the left side, parallel to the right heading; and for the purpose of checking the alignment and for ventilation, this was connected with the first heading by cross-drifts every 328 ft. A third small heading was then driven at the summit of the arch, and openings of 43-sq.ft. cross-section were driven to this heading from the two side headings every 60 ft. This third heading was then widened, and the excavated material was dropped through the cross-drifts



HEADINGS IN THE MARSEILLES-RHONE CANAL

into cars operating in the side headings. The top heading was then lowered, and finally the connection with headings 1 and 2 was accomplished as shown in the accompanying sketch.

In the meantime the footings for the masonry arch were laid and the arch centering was erected, being supported on the unexcavated core of the tunnel. The masonry of the arch ring was laid in sections 19 ft. long. Every third one of these sections was built, and then the intervening rings were undertaken. After the completion of the arch masonry, the remaining core was removed.

Before the tunnel proper was begun, two shafts 11.48 ft. in diameter, distant 8,200 and 17,800 ft. respectively from the south portal, were constructed, the former having a depth of 460 ft., the latter of 230 ft. These will serve for the ventilation of the tunnel.—*Engineering News.*

How The Repair Man Sees It

By Harry E. Scott*

How many mine superintendents would stand for an engineer taking a double-jack and pounding the piston of an engine or compressor, should it fail to do its work properly from overloading, or, in fact, from any cause? Without a doubt that engineer would next be seen headed toward the timekeeper's office with a nice large can on him. This holds good on everything in the mechanical line with one exception—that is, the misused and neglected air drill of all kinds and makes.

The management is always kicking about the cost of repairs; the foreman, about the footage and tonnage; the shift boss, about too much time being lost setting-up, getting steel, water, etc. The machine man kicks all of the time—the ground is too hard or too soft, the drift too high or too low, the air poor, the drill no good, the steel poor, and many other things too numerous to mention. They do not stop to consider that on the modern drills they are making machine runners much faster than they did years ago, when a man had to know more than the difference between the chuck and the crank before he could draw a machineman's check.

At the present time a young fellow who knows nothing about mining, and has never broken any ground except by the acre or in digging trenches for some of the warring nations comes into a mining camp. He rustles the proper official and gets a "job" mucking. In about a week the shift boss goes down the hole in the morning and is short a machine runner. The young fellow is not much force on the muck-stick as yet, possibly the poorest mucker in that stope, and as the shift boss does not care to spoil a good mucker, he puts the new man on a drill of the unmounted type. The latter knows nothing about it and is told practically nothing except that he must get "rock in the box" and lots of it.

The young fellow wants to make good, as there is more money and more glory in being a machine man than in being a mucker. He is shown where to drill, makes a few trips to the level for drill, hose, and steel, and at last everything is ready. He has no oil, but that makes no difference; it will run, so needs no oil. He has no trouble until the hole is two or three feet deep; then the steel sticks from one of many causes and refuses to rotate. He makes it turn by twisting on the handles, and about the second twist the machine stops.

When the shift boss arrives, making his rounds, the drill is sent to the shop, the rotation on the bum. Of course the machine man did not break it—it just stopped, so he says.

In from one to two hours it comes back. He is in a hurry now to make up for lost time, so he grabs a steel and rams it into the chuck. The hole is not large enough for the water tube and when the steel is taken out of the machine the tube comes with it; then back to the shop.

*Morenci, Ariz.

This performance continues for about three days if someone does not take pity on him and put him wise; then he wonders why they handed him his time. It would have been much better from the efficiency standpoint, to have taken time, possibly 30 min., and explained enough about the drill to get him started right, provided there was not an experienced man on the job.

The older men on this type of drill are nearly as bad as the green ones. Their troubles consist chiefly in running without oil, using the air and water connections for handles and breaking them off, dropping machines down ladderways instead of letting them down with a rope, taking drills apart underground and putting them together incorrectly or losing some of the small parts, and many other things that do not increase the efficiency or life of the machine. In a large percentage of breaks on air drills it is not the fault of the drill, but of the man behind it.

In the running of air drills of the mounted type we see some foolish things, which at times are amusing, such as throwing wrenches, hammers, steel, pounding the chuck, piston, drill or anything that happens to get in the way, because the machine will not run. It would be much easier to line up to the hole or change the bent steel for a straight one and let the machine do the work than to pound it in with a hammer or chuck wrench.

In drills of this type there are many things for the efficiency man to consider, of which the following are a few: The setting-up of the machine in the proper place and distance from the face, having it close enough to get the cuts at the proper angle to break well in hard rock and far enough away to make changes in steel without too much trouble and delay. The machine should be oiled at least twice a shift with good oil—not too light, as it will blow through the drill and do very little good. The heavier oil may gum somewhat, but it is better than the light oil, which goes on through and leaves the machine dry after the first hole.

The following tests, made in a repair shop, of three different classes of air drills show the wisdom of sending drills to the shop to be overhauled and cleaned at proper intervals: A piston machine was tested in the shop and consumed 195 ft. of free air per min. It was overhauled and a new front-head leather used, then tested again, taking 117 ft. at the same pressure. A stoper consumed 101.5 ft.; after cleaning and oiling, 75.6 ft. A jackhamer took 79 ft. on arrival and 63.4 when overhauled. In the two latter drills absolutely no new parts were used.

If the air drill was given a small percentage of the care and attention that other machinery receives, the efficiency would be greatly increased.

Handling a Long Heavy Cable Underground

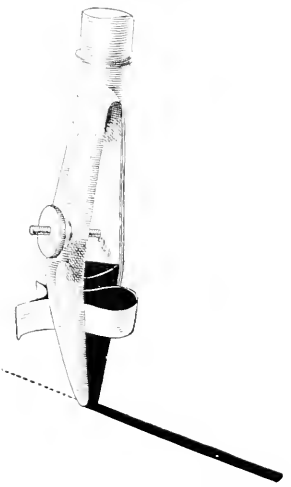
By James Humes*

At the Silver King Coalition mines in Park City, Utah, a cable, capable of carrying 800 hp. at 2,300 volts, and weighing about 6 lb. per ft., was taken into the tunnel in sections 1,200 ft. long. The reels that held these sections were too large to go in the tunnel. The cable was therefore fastened to the electric locomotive and strung out on mine cars spaced about 30 ft. apart. This scheme worked all right on the straight track, although some trouble was experienced on the curve to keep the small cars from tipping over. Despite this slight trouble, the scheme proved a very satisfactory one.

*Superintendent, Silver King Coalition Mines Co., Park City, Utah.

A Pen Kink for Draftsmen*

It is often necessary to draw heavy lines in the drawing office. By putting a piece of bent drawing paper between the blades of a tracing pen as shown in the illustration,



A DRAWING PEN FOR HEAVY LINES

thus increasing the capillarity and flowing friction of the ink, very heavy lines can be drawn and blots at the end of the lines avoided. The pen can also be filled with more ink.

*A. O. Alexay, in "American Machinist," Oct. 28, 1915.

Paint Required for Structural Work

In a pamphlet entitled "Engineer's Handbook on Protective Coating," published by the Goheen Manufacturing Co., paint engineers, Canton, Ohio, are given tables which show that for highway bridges the amount of paint required varies from 0.014 to 0.028 gal. per 100 lb. of bridge, for lengths of span varying respectively from 300 to 20 ft. For single-track railway bridges the paint required is 0.008 gal. per 100 lb. of bridge, regardless of the length of span.

For I-beams the amount required varies from 0.46 gal. per ton of 3-in. I-beams to 0.16 gal. per ton for 24-in. beams. For channels the amount varies from 0.48 gal. per ton for 3-in. beams to 0.22 gal. per ton for 15-in. beams. For buildings in general, 12 lb. of iron will average 1 sq.ft. of surface requiring painting, to which is to be added 10% for corrugations where corrugated iron is used.

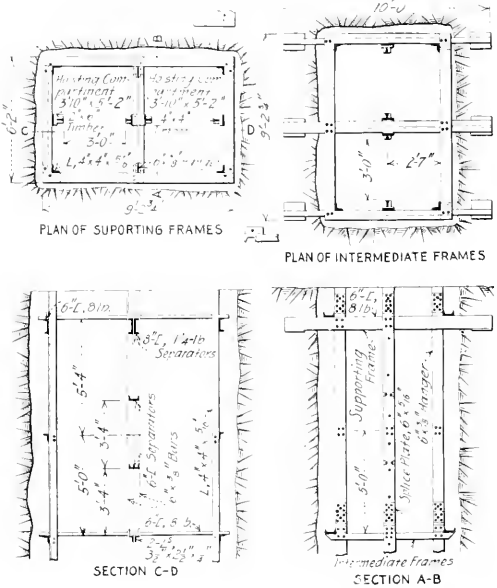
The approximate cost for labor per ton for applying the paint, working on the ground, is equal to the cost of paint per ton of steel. For elevated work anywhere

from 10 to 50% should be added to the cost of labor on the ground, depending on the amount of scaffolding and climbing necessary in the work.

For steel-riveted pipe the number of gallons required per lineal foot of pipe equals the sum of the inside and outside diameters in inches, multiplied by 0.000362 for first coats and by 0.000174 for second and succeeding coats, adding 3% for laps. All figures are for one single coat, except as noted, and are for paint manufactured by the Goheen company.

Steel Shaft Timbering*

At the Los Ocotes copper mine in the State of Oaxaca, Mexico, an 800-ft. shaft was timbered with steel, the details of the shaft-set being shown in the accompanying sketch. Supporting, or bearer, sets made up of 8-in. steel channels were cemented into hitches cut in the side of the wall. These supporting sets were installed just below



DETAILS OF STEEL SHAFT TIMBERING, LOS OCOTES MINE

the collar and at 240-ft. intervals in the shaft. All the steel, before being installed, was painted with a mixture of coal-tar and turpentine. From the surface to the 600-ft. level, sets were put in 10 ft. apart. From the 600- to 800-ft. level, because the ground showed a tendency to cave, the sets were put in every 5 ft. The lagging of 2-in. planks was laid lengthwise between the sets.

For timbering this shaft about 73 tons of steel was required, costing approximately $100. United States currency, per ton laid down at the mine. A steel gallows frame was erected containing 15 tons of steel, which cost about $140, United States currency, per ton laid down at the mine. This is at the rate of 5c. and 7c. per lb. and does not include the cost of erection.

*Abstract from article by R. H. Cromwell in "School of Mines Quarterly."

Telling Time with a Compass

It is commonly known that points of the compass can be determined by the use of a watch. By pointing the hour hand toward the sun, a bearing half way between the hour hand and 12 o'clock on the watch, is true south.

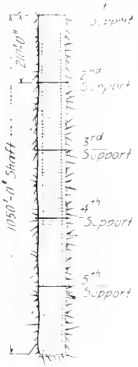
It is not generally known that time can be told by the compass with equal facility. Take the true azimuth or bearing of the sun and subtract from it 180°; multiply the remainder by the fraction $^1/_{15}$, and the result will be the hours before or after 12 o'clock noon.

How Electric Blasting Saves*

In blasting of all kinds, the most modern method is firing by electricity. The apparatus necessary to use depends on the kind of blasting, but from the following list one can easily select the proper ones for his work: Blasting machines, electric blasting caps, waterproof electric blasting caps, delay electric blasting caps, delay electric igniters and electric squibs.

Where electric power is used this can be substituted for blasting machines with better and more satisfactory results, provided the proper voltage and amperage are used.

In coal mining, ore mining, tunneling, shaft sinking, etc., where it is necessary that all charges do not detonate at the same time, it is economical to use either the delay electric blasting caps or the delay electric igniters. These can be used in the same circuit with the electric blasting caps. By their use the various charges can be detonated at different intervals as desired.



Advantages of electric firing are:

1. Charges of explosives can be detonated at the time and in order desired.

2. There will be no hang-fires, which often happen when using fuse and blasting caps.

3. In shaft sinking, should the hoist refuse to work after a round of holes with fuse is lighted, the shot-firers' lives are in great danger. This is entirely eliminated, as the charges of explosives can be detonated from the surface.

4. The inconvenience and danger from misfires because the fuse has failed to burn through or because it has been damaged from storage are eliminated.

5. Because the electrical-blasting method is economical, safe and sure, and therefore cheapest in the end.

Explosives for Sheet-Ground Mining in Joplin

In a paper prepared for the Gogebic Range meeting of the Lake Superior Mining Institute in September, Edwin Higgins, mining engineer of the Bureau of Mines, Ironwood, Mich., states that in the sheet-ground mines explosives count one of the chief items of mining expense, varying from 20% to as high as 30% of the total cost. A box of powder breaks from 30 to 45 tons of dirt, according to the nature of the ground.

Details of Milling and Smelting

Truax Zinc-Slag Treatment

Sewall Truax, of Cañon City, Colo., has patented (U. S. Pat. No. 1,155,628, assigned to the Granadena Mining Co., an Arizona corporation) a method of treating zinc-bearing material, especially zinc slags, by passing them in a fluid condition over finely divided reducing material, such as coke or carbon, the particles of which are prevented from passing into the fluid by being mixed with a binder such as clay.

The lining or bottom of the furnace is made of such a mixture of fine coke and clay rammed into place. A good mixture consists of coke of graduated sizes, from a maximum of 1-in. pieces down to fine dust, and 25% or more of a plastic clay. The furnace is heated by means of oil, pulverized coal or other suitable means, and as the slag or other zinc-bearing material comes in contact with the coke in the furnace bottom, the carbon monoxide formed by the action of carbon on zinc oxide or zinc silicate, rises in small bubbles through the melted mass and comes into intimate contact with a further portion of zinc oxide or silicate, liberating metallic zinc and producing carbon dioxide, which rises and passes off with the vapors of zinc, and at a lower temperature oxidizes the zinc again to oxide in case no free oxygen is present. Usually oxygen is present in the atmosphere of the furnace, and so zinc oxide and carbon dioxide are given off in the vapors. The zinc oxide may be collected in a baghouse in the usual manner.

The consumption of coke is stated to be about 20% of the zinc driven off, or in the case of slag containing 10% zinc the consumption of coke is about 2% of the weight of the slag treated. Experiments indicated that zinc above 0.5 or 0.6% of the weight of the slag is readily removed. The carbon and clay are replaced by "claying" the sides and bottom of the furnace with the brasque.

*

Preparing Pulverized Coal for Reverberatory Furnaces

E. P. Mathewson states that in many places reverberatory copper-matting furnaces using pulverized coal as fuel can be operated more cheaply than blast furnaces, even where the coke consumption in the blast furnaces is as low as 8% of the charge. He summarizes[1] some of the main considerations in the successful use of pulverized coal in reverberatories, as follows:

Coals varying in ash from 5% to 23% have been used successfully in pulverized form. Two points are essential for success: The coal must be dried below 1% moisture before pulverization; and the pulverization must be carried to a very fine point. Preferably, not over 5% of the pulverized coal should rest on a 100-mesh screen, while 95% should pass through 100-mesh screen; not over 20% should rest on 200-mesh screen, while 75% should pass through 200-mesh screen. The flame is as easy to handle as gas; the ash is caught to the extent of 50% in the flue connection between the furnace and the waste-heat boiler, the balance being absorbed by the charge.

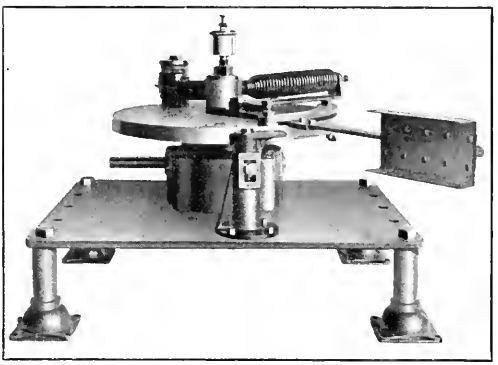
Bardill Sampling Machine

By J. O. Bardill*

This machine was designed for sampling wet and sticky mill concentrates and similar materials. The photograph shows the construction. The principal elements are a turret and its worm-gear drive, incased in an oil-tight housing. A cutter arm is pivotally mounted on the turret and revolves in unison with it, except through about 40° in each revolution, while it is being held stationary by a vertical detent bolt.

The relative motion between the turret and the cutter arm effected during this 40° period of inactivity of the cutter arm produces tension in the coil spring shown, which is exerted between the turret and pivoted cutter arm. A cam underneath the rim of the turret releases the



THE BARDILL AUTOMATIC SAMPLER

detent bolt at the proper time, causing the cutter to pass rapidly through the stream owing to the spring action independently of the motion of the turret.

The action of the cutter arm is extremely rapid, and it is suddenly stopped by its opposite end coming in contact with a rubber buffer post. This absolutely clears the cutter of any material that might adhere. The material is deposited in a receiving box properly placed, and the cutting action and delivery are done so neatly that there is no spilling. The power required is so slight that the turret may be operated through its entire revolution, and against the spring action, by turning the wormshaft by hand.

Reference to the diagram shows that the machine may be placed in close quarters, only about 12 in. being required vertically in the stream between discharge of hopper and top of conveyor belt.

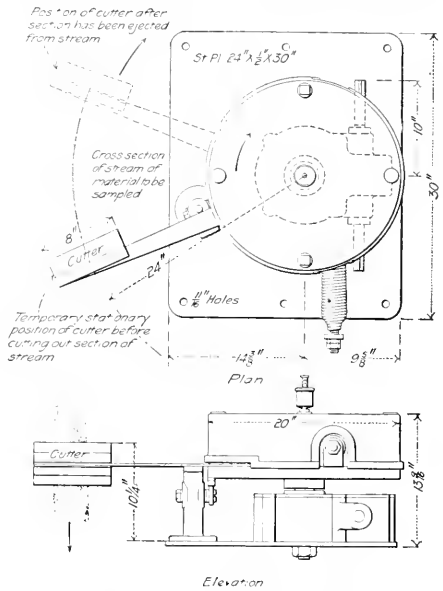
The machine may easily be made into a self-contained, portable affair by mounting a small driving motor on the base plate.

A sample removed from two carloads containing wet lead concentrates weighing 136,940 lb. and delivered

*150 Lafayette Ave., Palmerton, Penn

from the storage hopper to a conveyor belt by means of a 6-in. screw feeder weighed 495 lb. The stream was cut six times per minute and the dimensions of the cutter were 4 in. wide and 8 in. long. The length of cutter has no bearing, of course, so long as it is sufficient to take in the entire stream. This sample was produced by 840 cuts, 0.59 lb. per cut, percentage of total weight 0.39. Expressing this in terms of volume, each 0.83 cu.ft. had removed from it 5.6 cu.in. in one cut.

Since 140 min. were consumed in handling this material by the conveyor running at a speed of 275 ft. per



THE BARDILL AUTOMATIC SAMPLER

min., these concentrates were distributed in the form of a band approximately 38,500 ft. long, from which 840 cuts were removed at intervals of 46 ft. The analysis of this sample checked absolutely with a "one-in-ten" shovel sample taken from this lot.

Smelting at Anyox, B. C.

Smelting operations at the Granby Consolidated Mining, Smelting and Power Co.'s plant at Anyox, B. C., are gradually rounding into shape as the peculiarities of the ores are becoming better understood and necessary changes in equipment made to conform to the conditions now being established as best suited to economical work. The usual difficulties of starting a new works were augmented by the large amount of fines on the charge, the increasing content of silica and the aluminous character of the ores.

The reports for the year ended June 30, 1915, of W. A. Williams, superintendent of smelters, and of A. J. Bone, superintendent of the Anyox plant, give an interesting résumé of the progress that has been made in working out the metallurgy at this plant. The works was started in March, 1914, and the problem was not merely to smelt the Anyox ores, but to determine conditions of maximum tonnage and minimum expense for a new property. Commenting on the progress that has been made, Superintendent Williams says:

> We commenced operations as a pyritic plant, using low coke and very little flux, No. 1 ore being used as a base to smelt No. 2 ore. The ores have not come to us as free from inert materials, such as dike and schist, as we could wish. They have been more or less erratic as to the silica content from day to day, and the tendency in both ores is to higher silica and alumina. This fact, coupled with the shipment of about 100 tons of foreign ore per day, has made it hard to operate the furnaces as originally intended, and the coke and flux percentages have risen to some extent. With the greater development of our own orebodies and with the better storage facilities at the mine and smelting plant, this should be materially helped. We have been trying to make a converter grade of matte in the first operation, but have found it to be the better practice to regrade our matte. The making of converter grade of matte in the first smelting, we believe, will eventually be accomplished.

Several changes and additions to equipment have been made with the purpose of improving operating conditions and lowering cost. These include new charge cars, matte machine, increased crane capacity, a skull grid, silica bins over converters and additional ore-storage bins, all of which have been charged to "Operation." A fourth blast furnace has been constructed and placed in operation, and an agglomerating plant for handling converter slag, flue dust and similar materials. Discussing the smelting operations in more detail, A. J. Bone says:

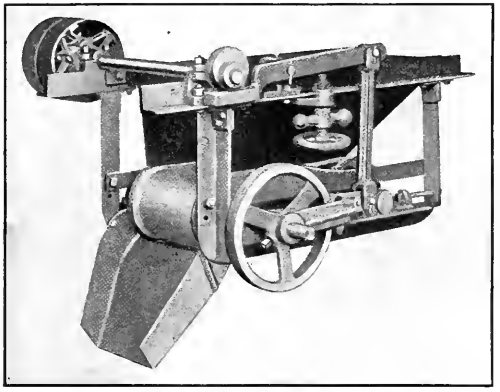
> The ores smelted covered a wide range in analysis, from low silica, low alumina, requiring quartz and little coke to smelt, to the other extreme of high silica, high alumina, taking a basic flux and higher coke. Of late the tendency has been toward higher silica content. We are also receiving about 100 tons daily of siliceous custom ore. The result of these conditions is to curtail the use of quartz in the blast furnaces and increase the consumption of limerock and basic "Mamie" ore, and consequently the percentage of coke.
>
> It may be suggested that our slag is comparatively low in silica. The obvious remedy for increased silica in the ore would be to make slags higher in silica. In this connection it should be remembered that the bulk of the iron that enters the slag is oxidized in the furnace and combines with silica in conformity with the principle underlying slag formation in pyritic smelting, namely, that the temperature prevailing in the focus determines the particular ferrous silicate which results. Working along natural lines, our endeavor would be to make more slag in the furnace—not to alter its character. In other words, by obtaining a greater degree of oxidation, more ferrous oxide will be furnished to slag silica and at the same time make less matte but of higher grade.
>
> During the last quarter of the year, the first matte, when too low grade, has been resmelted with siliceous ore and brought up to 20% or 25%. Even this grade can be considered low as converter mattes go, but with it the converter department can produce at the rate of 3,000,000 lb. per month with ease. One of our chief concerns is to make matte of suitable converter grade in the first smelting, and though no permanent success in doing this can yet be recorded, it is not improbable that efforts in this direction will be successful.
>
> Recently the system of feeding the furnaces was improved through the adoption of Anaconda-type charge cars. These permit a more favorable placing of the charge, the advantage of which was immediately reflected in a marked decrease in crust formation. Incrustation in the upper part of the furnace shaft has been responsible for terminating fully 90% of the campaigns. These for the year were very brief, averaging only 13.6 days, but with the new cars, longer campaigns are the rule. A saving of labor on the feed floor was also made possible by the new cars.
>
> The prolific fall of low-grade, corrosive matte imposes a duty on furnace connections and settlers probably without precedent in the practice of copper smelting. Means to cope with this condition have been devised, and the furnaces are no longer subject to the frequent interruptions by purely mechanical mishaps, which proved so embarrassing in the past. In the converter department, new steel silica bins were built and so placed as to permit feeding silica to the converters without resorting to the use of cranes.

Heat Losses in an Electric Steel Furnace were recently determined by W. H. Wills and A. H. Schuyler as being 12.5% through the door and tap hole and 7.3% through the electrodes (September meeting, American Electrochemical Society).

Mining & Metallurgical Machinery

Hamill Belt-Driven Ore Feeder

A new type of ore feeder is presented in the Hamill, the construction of which is shown in the accompanying illustration. Its moving parts consist of a short conveyor, or endless belt, intermittently propelled by a bell crank engaging a friction wheel on the headshaft. The bell crank is actuated either by a pulley and eccentric, on the belt-driven type, or by a fork-lever reaching under the tappet for the stamp-actuated type. As the bin gate can be left wide open and the ore flowing loosely to the



A VIEW OF THE HAMILL BELT-DRIVEN FEEDER

feeder belt, there is no bridging, blocking or crowding, irrespective of the size of the material. Coarse rock is fed as easily as fine material, and there are no idle strokes. By reason of this steady, regular delivery, the feeder is said to increase the capacity of stamps and other mills. It is adjustable while running, and can be set to longer or shorter stroke, or to nothing, independently of the speed of the driving pulley or rockshaft.

The machine is patented and is distributed by Edward Maag, 535 I. W. Hellman Building, Los Angeles, Calif.

Golden Glow Headlights

The Esterline Co., of Indianapolis, Ind., has been working to obtain a nonirritating light adapted to commercial uses and reflected in an intense but nondazzling beam, resulting in the Golden Glow mirror reflector. The ingredients used in making this glass are such as to give it a rich golden green, producing light as near the color of molten gold as it is possible to obtain.

There have been over 6,000 of these Golden Glow headlights in use in electric-railway and tunnel service, and in four years not a single accident has been recorded because of lack of light or inability to see the car approaching. A similar record should be obtained in mine properties, for the men ahead are not blinded or confused; miners can work in a seam at close range or at a considerable distance with equal ease, and in fog or dampness it provides protection not possible with any white light.

The "Simplate" Valve

To insure higher mechanical and volumetric efficiency and to simplify air-compressor cylinder design, the Chicago Pneumatic Tool Co., 1080 Fisher Building, Chicago, Ill., has recently placed on the market the "Simplate" valve, which is of the flat-plate design. The valve has several distinctive features and the chief advantages claimed for it are that it is simple; that its plates are independent in action, one of another; that each plate has

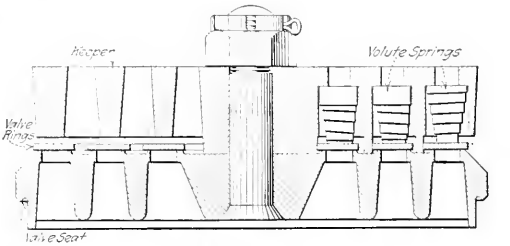


FIG. 1. "SIMPLATE" DISCHARGE VALVE

its individual springs; that the tensions of the springs on the inlet and discharge valves differ according to the density of the air handled; and finally, that it is applicable to all positions and conditions.

Fig. 1 shows a section through a discharge valve. The seat is cast from a special alloy steel, heat-treated, oil-tempered and ground true on one side. As shown in the

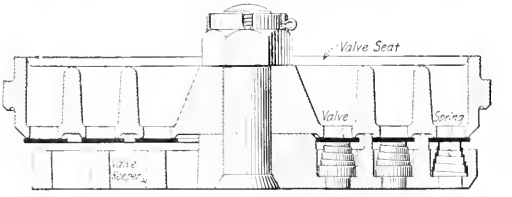

FIG. 2. "SIMPLATE" INLET VALVE

illustration, the seat has circular ports and it is machined so that the raised portion, or the point on which the plates rest forming the joints, is narrow, thus reducing the unbalanced area of the valve. The keeper is of the same material. It is provided with suitable ports for the free passage of the air through it and also furnishes guides for the valve plates and pockets for the valve springs. The latter are of the volute type and are made of high-grade crucible steel. The valves are simple concentric steel plates of uniform section, with a separate and independent plate over each port. Each plate is independently governed by its own spring, hence the action or opening

of each valve is entirely independent of the other. Should one of the plates open, the next one to it does not need to move unless the speed conditions should demand it. Ordinarily the outer plate opens when the compressor is running at slow speed, when running at intermediate speed two plates operate, and at full speed all valves are

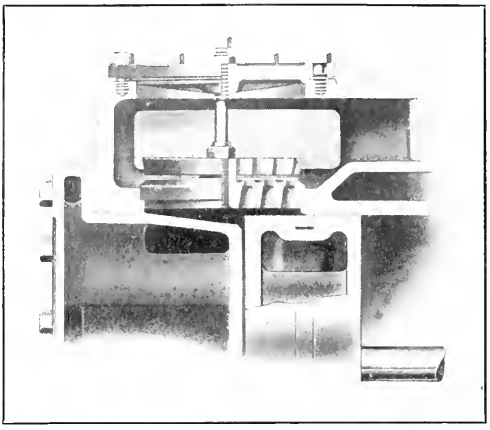

FIG. 3. POSITION OF VALVES IN AIR CYLINDER

open. The parts making up a complete valve are assembled and held together by a nickel-steel stud and castle nut, and when this nut is tightened in place it is held by the cotter pin.

As shown in Fig. 2, the construction of the inlet valve is similar to that of the discharge valve. It differs in that the keeper is thinner and the springs have lighter tension. On account of this difference in thickness, inlet and discharge valves cannot be reversed. The spring tension on the inlet valves is light in order to derive the full benefit of the various openings of the different plate, when the piston speed is changed. For example, with an inlet valve of the size shown herewith, the spring tension is so calibrated that the outer plate opens with a pressure of but ¼ oz. per sq.in., while 1 oz. will open the intermediate plate and 2½ oz. the inner plate. The valves are said to be noiseless in operation, and their

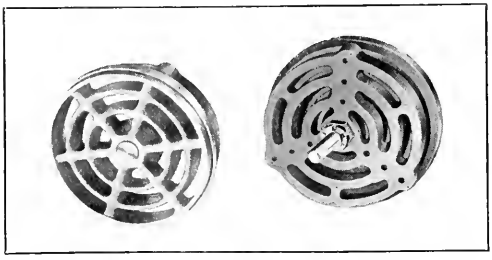

FIG. 4. THE "SIMPLATE" VALVE

location in the cylinder is convenient for examination or repair, as indicated in Fig. 3. Top and bottom views of the valve are shown in Fig. 4. It is equally suited to high- and low-pressure work and requires no lubrication. A feature worth noting is that all valve parts are interchangeable.

Gasoline Shovels Auxiliary to Steam Equipment

There are localities where smoke ordinances, the cost of coal and water or the demand for licenses for firemen and engineers prevent the use of steam shovels and make advisable the employment of those driven by gasoline power if certain handicaps of the latter can be overcome. The gasoline shovel therefore has been designed to satisfy a certain limited demand, rather than to produce a machine in competition with the steam shovel. Gasoline shovels will probably be restricted to medium and light excavation.

Several designs of gasoline-power shovels have been brought out recently, among which is that of the Marion Steam Shovel Co., of Marion, Ohio. The following notes on the equipment and operation of this type have been obtained from the company.

The Marion design has been developed only in the revolving type. All operations are performed by power from one engine and the operation is controlled by friction

FIG. 1. REVOLVING SHOVEL WITH GASOLINE-ENGINE DRIVE

clutches of the outside-band type. The engine is a constant-speed, four-cylinder, four-cycle vertical marine type with a throttling governor, jump-spark ignition and high-tension magneto. It is splash-lubricated and has a cooling-water pump. A flywheel is carried between the engine and the load to relieve the crankshaft of stresses due to sudden changes in torque. Any fuel can be used down to that of 39° Bé., provided the proper carburetor is employed.

On the end of the engine shaft is a bevel pinion which meshes with two bevel gears loose on a reversing shaft (*A* in accompanying view). One or the other of these is connected to the shaft by friction clutches. Placing the lever for operating these clutches on center will release both clutches. Geared to the reversing shaft is the hoisting drum *C*. This is of differential or stepped type, instead of the usual straight barrel seen on steam shovels. This scheme is employed to give greater pull and slower speed on starting the dipper out of the pit and an increased speed with lighter pull when the dipper clears the bank. In this way the difficulty of using a constant-speed drive is minimized. Forward of the hoisting-drum shaft and connected to it by an intermediate shaft *E*, with gears, is a pair of reversing gears with friction clutches—an arrangement similar to that on the main reversing shaft just mentioned. These control the crowd-

ing of the dipper handle, and are both governed by a single lever arranged so that when in central position both frictions are released and a brake *G* is set to hold the dipper handle in any position. Meshing with the reversing bevel gears on the intermediate crowding shaft is a bevel gear on a shaft *H*, running at right angles and having telescopic joints connecting to the crowding gear on the boom. This allows for variation in height of the boom.

The propelling of the shovel is done from a friction clutch and gear *J* mounted on the end of the hoisting-drum shaft. The gear meshes with another gear keyed to a horizontal shaft running directly over the rotating center. Here the shaft carries a bevel pinion, which engages with a bevel gear on the vertical propelling shaft, the lower end of which drives the shovel exactly as on the same manner. The gasoline shovel is a one-man machine—the elimination of the boiler makes a fireman unnecessary. It is not necessary for the operator to leave the shovel levers to look after the engine.

The gasoline type of shovel can be converted into a single-motor electric shovel by the substitution of an electric motor of the proper capacity in place of the gasoline engine. With the control gearing described a constant-speed alternating-current motor may be employed.—*Engineering News.*

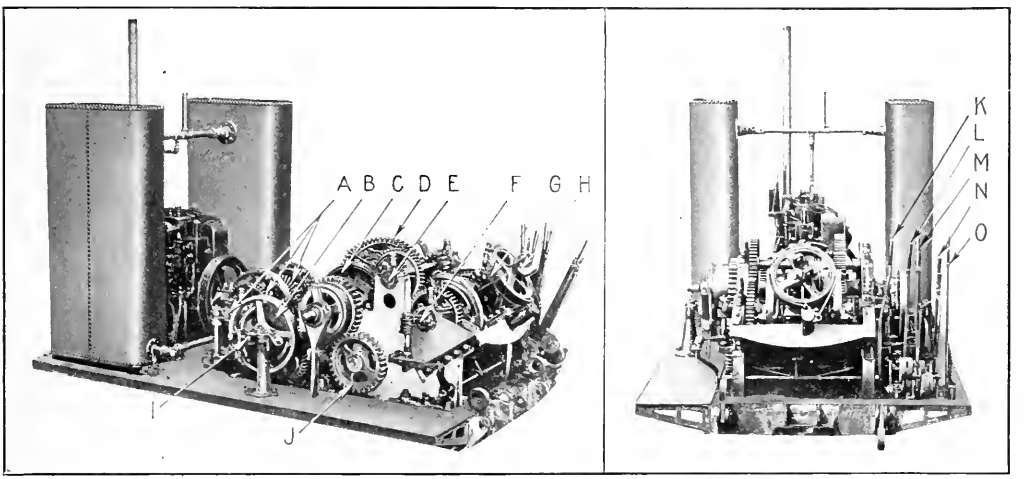

FIG. 2. TWO VIEWS OF POWER AND GEARING UNIT OF A MARION GASOLINE SHOVEL

the steam type. Reversing the drive is done at the main reversing gears already noted.

The shovel is swung by a spur gear carried on the main reversing shaft. This gear engages a corresponding spur gear fixed on a swinging shaft *I*, each end of which has a drive-wheel keyed to it and a corresponding friction housing *B*, which is keyed to a gear mounted loosely on the same shaft (with bronze bushings). Both of these gears on the swinging shaft are controlled by outside band frictions, duplicates of those on the reversing shaft; each gear engages another gear keyed to a short shaft below and forward. At the outer end of each short shaft is a bevel pinion meshing into a swinging crown gear on a vertical swinging shaft. The other end of each of these last shafts, exactly as on a steam shovel, carries a spur pinion meshing with a large rotating gear on the lower frame of the shovel. Since there are two swinging mechanisms between the bull wheel and the intermediate swinging shaft, the shovel can be turned in one direction or the other, according as one gear or the other on the intermediate shaft is engaged.

The operator's control of the gasoline shovel is kept identical with that of a corresponding steam shovel; the operating levers have the same position and work in

National Matheson Joint Pipe

In a recent bulletin on Matheson Joint Pipe, the National Tube Co. calls attention to the following: "There is no economy in laying cheap pipe. Its life is too short. There is great inconvenience and disturbance in taking up a long flow line and replacing it with new pipe, and the first cost of the temporary system is practically thrown away."

It is claimed that National Matheson Joint Pipe has been in use from British Columbia to Mexico for periods as long as 30 years, in earth impregnated with alkali, sulphur and arsenic, and is still almost as smooth inside and out as when first laid.

Asbestos-Protected Metal Skylight Construction

A form of puttyless skylight construction is being introduced by the Asbestos Protected Metal Co., of Pittsburgh, Penn. The glass is held between asphalt cushions, protected by asbestos felt above and below, and the entire joint is shielded above by a protected-metal cap and below by a protected-metal gutter that drains off any condensation water. In sawtooth construction or continuous monitor sash, the condensation gutter is omitted. The caps form a convenient support for the window cleaners' boards, which do not touch the glass.

The Alaska Gold Mines Co.

Rumors have been current that all is not well with the Alaska Gold Mines Co., operating in the Juneau District, Alaska, which rumors have been recently reflected in the stock markets, especially that the ore is not turning out so high as expected. Referring to this, D. C. Jackling informed the *Boston News Bureau* that an unexpected occurrence of low-grade schist was encountered on the fifth level, from which point it had been hoped to draw high-grade ore with which to sweeten the lower-grade ore being mined near the surface. Strangely, not one of the many drill holes cut into this low-grade intrusion. It is estimated that three or four months will be required to remove this material and put the mine in shape to supply average ore to the full capacity of the mill.

Up to the end of October the new mill had treated about 900,000 tons of ore, assaying about $1.25 per ton instead of the expected $1.75 per ton. Ore is now being mined and milled for 60c. a ton, and the tailings are assaying only 20c. per ton. At present the company is treating about 5,000 tons of ore per day, and it is expected that by the first of next year the rate will be about 7,000 tons.

Copper Supply of Great Britain

The following is from the *Statist* of Oct. 23, 1915:

As regards copper, it may be pointed out for the benefit of the uninitiated, that the metal resulting from the smelting of ores contains impurities that have to be removed before the copper is suitable for commercial use. There are two ways of refining this rough copper, one being by passing the metal through the furnace again and the other by treating it by an electrical process that dissolves the rough copper and redeposits it in a pure form, the impurities sinking to the bottom of the tank. By the first process any gold or silver contained in the rough copper is lost, but by the second process it is recovered, hence refiners have more and more favored the electrolytic process to the disadvantage of the furnace treatment. Now British refineries are mostly of the furnace type, treating rough copper and converting it into Best Selected. On the other hand, the American refineries are mainly of the electrolytic variety and produce the well-known electrolytic copper. Each of these coppers has its special spheres of utility, "Best Selected" being mainly used in the brass trades, while "electrolytic" is used largely for the manufacture of electric wire, etc.

It has been a grievance with the British copper refiners that the government did not patronize their product more extensively. They allege that years ago leading government departments buying copper were unduly influenced to favor American electrolytic at the expense of British Best Selected, and that they, moreover, were induced to fix so high a specification for Best Selected that it became most difficult to conform to it, the result being that the supply was much less than need have been the case, while the government bought more American electrolytic copper than it need have done. Even within the last few months we have seen large quantities of rough copper shipped from here to America under special permit for refining by the electrolytic process, the resulting copper being brought back to this country, and the British makers of Best Selected have got restive because they want the rough copper themselves. There is no doubt that as a commercial transaction the purchase of rough copper here at the very cheap prices that were paid for it and its conversion into electrolytic in America were thoroughly justified, but the British refiners feel that they are being unfairly treated by this cutting off of the supplies upon which they rely for carrying on their operations, and they think, too, that the mere process of transferring copper from here to America in this way tends still further to increase the power over the market which American producers wield. They are, therefore, making protests in official quarters with a view to some alteration in this respect. It should be remembered that the copper that has been shipped to America in this way has not been shipped by producers, but by people who have bought it in the open market, and who have been able to make a handsome profit on the transaction. The British refiners, however, suggest that a much more satisfactory state of affairs can be brought about if the government require all Empire-produced copper to be refined in Empire-owned refineries.

As will be seen from the foregoing, Australia has already resolved that her copper shall be refined locally, and thus within the Empire, and an extension of this principle to cover all Empire-produced copper would have a large influence upon the world's copper trade. For years past a considerable portion of Australia's production of rough copper, for instance, has been sent to America to be refined, and naturally every extra ton that is placed under the control of American producers tends to strengthen their already powerful position. During recent years America has been stretching her tentacles further and further, until she has practically controlled the copper-refining industry of the world, and any step which our colonies can take to put an end to this supremacy is worthy of whole-hearted support. America, of course, has been able to pay more for rough copper, too, than British refiners, because by the electrolytic process the bullion values have all been recovered.

Apparently it has been nobody's business to insure that British copper was reserved for British use, and it has required a world-wide war to force home economic and commercial lessons. If we in England are still asleep, it is a matter for national thankfulness that the colonies are awake, but the British refiners should bestir themselves and get their houses in order for the new state of things that will come when the war is over

Revision of Mining Laws

The convention of mining men of the United States, who will meet in Washington, Dec. 16, by invitation of the Mining and Metallurgical Society of America, will be held in the auditorium of the National Museum, the use of which has been granted through the courtesy of Dr. Charles D. Walcott, director of the Smithsonian Institution.

All of the mining societies of the United States have been invited to send delegates to this convention, and through the United States Bureau of Mines all of the mine operators of the country have been notified and invited. Much interest in the meeting is being exhibited.

According to the tentative program, the first session will be held at 10 a.m. and other sessions at 2 p.m. and 8:30 p.m.

Japan's Mineral Output in July

The production of important minerals during July, 1915, in Japan, is reported by the Imperial Mining Bureau as follows: Gold, 557.089 kg.; silver, 10,847.955 kg.; copper, 5,385.453 metric tons; iron, 3,731.433 metric tons; coal, 7,109,052 metric tons; crude oil, 44,299,440 liters; and sulphur, 6,607.762 metric tons. Gold, silver, copper and oil showed increases and iron, coal and sulphur, decreases, as compared with the same month of 1914.

The Altai Railway Opened

Traffic on the Altai Railway, in Central Asia, says a Petrograd dispatch to the London *Times*, will open Nov. 4, fourteen months earlier than the date contemplated. The railroad, a private line 500 mi. long, will open up an immense and rich region of Siberia that hitherto has been without means of communication.

Chinese Currency-Reform Schemes have been so numerous that the latest one is perhaps to be accepted with some doubt. Under this silver coins are to be minted as follows: 200,000,000 one-dollar, 80,000,000 fifty-cent and 235,000,000 ten-cent coins. Copper, 275,000,000 twenty-cash (two-cent) coins, 858,000,000 ten-cash and 186,000,000 one-cash coins. This coinage is to be spread over 10 years.

Correspondence and Discussion

New Mining Taxes in Mexico

In Mexico the government divides the year, not into quarters, but into thirds, or *tercios*. The fiscal year begins July 1. The unit of mining field is the pertenencia, which measures a hectare (100 meters square) and is equal to about 2.4 acres.

The old Spanish mining code required properties to be worked, and to promote the industry it charged a light license or title fee and no yearly tax on the property. Instead, it taxed the gold and silver produced with a coinage or mining tax. All gold and silver exported had to pay this coinage tax. In the late '80s of the last century taxes were charged by the federal government of Mexico, as follows: Minting or export duty, 4.41%; interior revenue duty (3c. on each $5), 0.60; state duties, 1.50; federal supertax on the state duties, 0.45; stamps and assaying charges, 0.25; total, 7.21%.

In 1892 the mining law was revised and again in 1905. All old titles had to be renewed. The later law required all titles to carry internal-revenue stamps to the amount of 5 pesos per unit of mining field and further imposed a property tax on each individual mining property of 6 pesos per unit of mining field (pertenencia) up to 25, and 3 pesos per unit on the excess over 25 pertenencias.

In many ways the new mining law was an improvement on the old one, but silver mining, which had been Mexico's principal mining industry, did not flourish as well as had been expected. The price of silver was falling, and many properties of the old mining districts had to stop operations. New York quotation for silver in 1876 was $1.156; 1882, $1.136; 1887, $0.978; 1892, $0.871; 1897, $0.604; 1902, $0.522; 1907, $0.63.

It therefore was found necessary to reduce the production tax to 2½% federal export tax and 1½% state tax, plus 20% federal addition, and it stood at this figure until it was changed on Mar. 1, 1915, by decree of Carranza, which raised the title tax, or license, the property tax and the export tax. Objections were of course made by property owners, and the matter was brought to the notice of the Department of State in Washington.

On June 30, 1915, the Department sent a vigorous protest to its special representative, Mr. Silliman, in Vera Cruz, calling the attention of General Carranza to the pitiful condition of the mining industry in general and the foreign-owned properties in particular, and asking that protection be given to foreign interests holding and operating mines, and further that no more taxes be imposed "other than those fixed by the laws emanating from the constitution."

This brought from the Carranza government the following statement or argument, which, if it is to be taken seriously, gives an idea of certain Mexican revolutionary conceptions and ideas:

MEMORANDUM OF THE SECRETARY OF THE TREASURY (SECRETARIO DE HACIENDA) ON MINING TAXES

Translation by W. C. Thurston

In conformity with the laws of Mar. 25, 1905, mining properties paid taxes as follows:

Up to 25 pertenencias, 2 pesos Mexican gold per pertenencia per tercio (period of four months), or 1 dollar per tercio, ⅓ dollar per month.

From 25 pertenencias up, 1 peso Mexican gold per pertenencia every 4 months, or ½ dollar per tercio, or ⅛ dollar per month.

The exchange on New York from 1908 to 1912 reached an almost invariable point very close to ½ dollar per peso.

The decree dated Mar. 1, 1915, fixes the following taxes:

Up to 10 pertenencias, per tercio per pertenencia, 4 pesos Mexican gold, or 1 peso Mexican gold per month, or ½ dollar per month.

Up to 20 pertenencias, per tercio per pertenencia, 5 pesos Mexican gold, or 1.25 pesos Mexican gold per month, or ⅝ dollar per month.

Up to 50 pertenencias, per tercio per pertenencia, 6 pesos Mexican gold, or 1.25 pesos Mexican gold per month, or ⅝ dollar per month.

Over 50 pertenencias, per tercio per pertenencia, 8 pesos Mexican gold, or 2 pesos Mexican gold per month, or 1 dollar per month.

The decree dated Aug. 31, 1915, modified the above taxes temporarily, and only for the two tercios included between the months of July of this year and February next, as follows:

From July to October, per pertenencia, whatever be the number, 2 pesos Mexican gold, or ¼ dollar per month.

From November, 1915, to February, 1916, per pertenencia, for whatever be the number, 2.66 pesos Mexican gold, or ⅓ dollar per month.

From Mar. 1, 1916, the tax rate above mentioned as fixed in the decree of Mar. 1, 1915, will resume effect.

The law of 1905 favors monopoly, imposing upon the small properties (up to 25 pertenencias) double the tax paid by the large properties (over 25 pertenencias).

The law of Mar. 1, 1915, aims at a different purpose; that is, to favor the small properties, imposing lower taxes upon them than upon the large properties. This tendency is perfectly justified and is sanctioned by the proceedings of all civilized governments.

The decree of Mar. 1, 1915, imposes upon the large interests (over 50 pertenencias) double the tax levied on the small property (10 pertenencias).

The intermediate properties (between 10 and 50 pertenencias) pay an ascending proportional rate.

In conformity with the income-tax law effective in the United States, the small interests, with annual profits of less than $20,000, pay 1%; those whose profits are $50,000 pay 2%; up to $75,000, 3%; and so on successively to 7%, paid by those whose profits are more than $500,000 per year.

So it is seen that the large enterprises in the United States pay proportional taxes seven times greater than those paid by the small enterprises.[1] In conformity with the mining law which will commence to operate next March, the large properties (50 pertenencias) will pay only double the amount of taxes paid by the small properties (10 pertenencias).

As is seen, the progressive increase in the mining tax is very moderate when compared with the income tax.

Comparing the tax fixed by the new law for the small property with the old tax, it is seen that it is doubled, but this by no means indicates that it is a high one, because the old tax was exceedingly low.

A tax of ½ dollar per month per pertenencia cannot be called high, and ½ dollar per month is the amount that will have to be paid, beginning in March of next year.

There are some concrete cases which may be cited, of mining companies having more than 100 pertenencias denounced in one single mining district, and in some places they have been paying mining taxes during 15 to 20 years without doing one stroke of work on the ground denounced. The progressive tax tends toward eliminating these unjust and unproductive monopolies.

Some mine owners, attempting to show that the taxes are very high, argue by reducing to paper money the value of gold and comparing this to the amounts formerly paid by them when exchange was ½ dollar for one peso. This cannot be taken seriously, nor is it worthy of consideration. The

[1] Not true. The income supertax is levied on individuals, not on corporations.—Editor.

comparisons should be made between what they pay in gold and what they paid in the same money.

The only weighty argument thus far presented by those interested in the reduction of the taxes is that the great majority of mining interests have had to stop their work entirely or partially because of the European war and the state of intranquillity prevailing in this country. Precisely because this reasoning was considered just, the decree of Aug. 31, 1915, was issued, reducing considerably the rate of taxation without making the progressive increase, for the two tercios between July, 1915, and February, 1916.

The interested mine owners also call unjust the act that the taxes are collected in gold and not in paper money. They are not justified. For a long time export taxes, the stamp tax (that is, the revenue tax) on petroleum, forest exploitation, etc., have been collected in gold, and gradually it will be decreed that other taxes be paid in gold, until all fiscal collections will be made in this class of money.

This fiscal program of the government, tending to consolidate the monetary system, can in no way be called unjust. The business concerns that produce articles for exportation can object less than any other to paying their taxes in gold. These concerns sell their product for gold, but, on the other hand, pay a great part of their running expenses in paper money. Therefore they would be absurdly favored if they paid their taxes in paper money.

SPECIAL REPRESENTATIVE'S REPORT TO WASHINGTON

Vera Cruz, Sept. 13, 9 a.m.—To Secretary of State, Washington. Department's Sept. 11, 4 p.m., regarding mining taxes, Mexican Government's argument is:

First—Mining taxes have always been disproportionately low; with present depreciated currency they would be so absurdly low as to be entirely inequitable.

Second—In view of depreciated and fluctuating paper currency, the only proper and equitable unit is the Mexican gold peso, equivalent approximately to 50c. American.

Third—It is not inequitable that a product produced by labor paid in depreciated currency and sold for gold should pay its government taxes in gold.

Fourth—It is not unusual for paper currency to be of enforced circulation for the payment of public and private debts and at the same time be declared not legal tender for government taxes.

Fifth—The government's intention is to increase its revenue from productive mining properties, but not to the extent of embarrassing them or of confiscating properties that are not productive or that are undeveloped.

Observations—Inasmuch as the government has modified the decree of Mar. 1 and has expressed its willingness to deal with the owners of mining properties upon representation, it is respectfully suggested that the owners of mining properties take up their cases directly with the Secretary of Hacienda either through a commission from a given locality or by individual owners in person or through correspondence.—Silliman (State Department's Special Representative).

The Mexican argument refers only to the property tax and does not mention the tax on the product, which is by far the heavier burden on operating properties. In the argument every large business is considered a monopoly, and it holds that it is better and more just that the mining properties be divided into small units because some large properties have not done work for a number of years. It calls the aim of the new decree to bring this about "perfectly justified and sanctioned by the proceedings of all civilized governments." It therefore legislates against the principle of coöperation, association and concerted action. How a federal government promoting such principles can expect to promote modern industry or even to maintain itself is not indicated.

Evidently, in the hurry to collect taxes from those that still had property, the principles of taxation were twisted to suit the circumstances. This is shown by using the United States income tax, a tax on net profit, as a rule and guide for a tax on property, which is a totally different matter. Property may or may never produce income, and an income tax is not a tax on property, any more than is an inheritance tax.

Mine operators in Mexico will have to show and will have to convince the Carranza government that the new decree cannot possibly bring about a permanent increase in revenue, but that on the contrary, it would injure the industry and would in many cases make successful mining impossible. The yearly federal tax on mining property in Mexico is only a small part of the taxes the miner has to pay. The tax on production has always been excessive; it now has been made exorbitant and prohibitive, but this production or export tax is ignored in the argument of the Carranza government. Together with the state tax, it would be 10% on the assay value of the gold and silver produced, which most mining companies are unable to pay. It would stop production.

Mines may now and then be worked by individuals, but they will never give occupation to a mining population unless they are worked on a large scale, with sufficient capital to guarantee a steady production. This is generally beyond the scope of the individual. Capital has been invested in mining in Mexico judiciously or injudiciously, but always with faith in the permanency of existing laws after careful study of the same. To increase suddenly the taxes and change the laws is grossly unjust, because it disorganizes the carefully laid plans on which the working results of future years depend. Capital would be scared away from the country by such proceedings.

Since the yearly federal tax on mining property in Mexico is only a small part of the federal tax which the miner has to pay, the tax on production being ever so much more burdensome, it is useless to compare this special tax with the amounts paid in other countries.

In Mexico the miner pays for his mineral right according to the amount of surface by which it is covered, whether the ground is valuable or not, whether his work is profitable or unprofitable, whether he works or not; and moreover, he pays on his gross production. In the United States he pays a tax on his profits. Corporations are charged 1% on their profits, but there is no Federal tax in the United States with which the Mexican federal mining tax can be compared.

In Mexico the state tax is 1½% plus 20% additional federal supertax, or 1.8% on the gross product, and on the two million dollars produced it would be $36,000, profit or no profit.

The state taxes in the United States vary in rates and in ways of assessment. In the State of New York, in general, corporations are assessed upon their capital, "existing in money or property." If the capital were $1,000,000 and the profit $1,000,000, or 100%, the state would tax ¼ mill on the capital for each percent. of dividends or 2½%, or $25,000, but if the profits amounted to 20% on a capital of $1,000,000, the tax would be $5,000; if 6%, $1,500; and if there were no dividend, $750.

It is not possible to mention here in detail all other taxes, such as municipal taxes and the high taxes which the miner has to pay in Mexico on the supplies brought from the United States or other foreign countries.

In answer to the statement of the Carranza government that the federal mining tax has always been disproportionately low and that the new tax of one dollar per pertenencia per month is a moderate one, what else can be said than that it may be one of the last straws, and that when they break the camel's back the rider may be on foot?

New York, Nov. 5, 1915. A. J. R.

Editorials

Anaconda's New Metallurgy

In the *Journal* of May 9, 1914, there was an article outlining a new and vast plan for metallurgical improvements that had just been inaugurated at Anaconda. In summarizing this it was remarked:

> When the Anaconda plan is fully carried out the tailings discharged from its mills will carry only 0.1 to 0.2% copper, against the former 0.65 to 2.2%. Instead of recovering only about 75% of the copper of the ore, the recovery is expected to be around 95% and, best of all, the additional copper will be got at far less cost per pound than the present copper. Without increasing its ore production the company can increase its copper production by something over 50,000,000 lb. per annum and reduce its cost on the whole product by ¾c. per lb. or so; or it can reduce its ore production; or it can mine a lower grade of ore when that be advisable. However the management determines to work the thing out, it will benefit enormously by the great step that it is effecting in the conservation of its resources.
>
> Its other economies are of course of the first order of importance—the compressed-air hoisting, the electrification of the railway, the remodeling of the Washoe concentrator, the reconstruction of the Great Falls smelting works and the abandonment of concentration at Great Falls, saving the high cost of freight to there. These ought to do much more than merely offset the increased cost of living which Anaconda experiences alike with other mining companies.

At the time when that article was written, the contemplation of the Anaconda metallurgists was to go into copper leaching on a huge scale, but their attention had just been drawn to the possible economic superiority of the substitution of the flotation process for mechanical concentration, and it was suggested that they stood ready to abandon the leaching feature of their program in part or in whole if that should appear desirable. In fact, things turned out so and only the leaching unit then under construction was completed, it fitting in well for a special purpose, while steps were taken to convert the main Washoe concentrator into a flotation plant.

Since then about 18 months have elapsed, and the program of improvement is now about 75 to 80% done—completion being expected by the end of this year—and the Anaconda management feels that it may safely begin to check up with the original estimates and make up its mind as to what is going to be accomplished in a commercial way.

In September, 1915, about 8,000 tons of ore daily was treated by the new process. Applying the data derived from that month to the production figures in 1913 and computing on the basis of 14c. per lb. for copper, it is reckoned that the saving would have been about 7¼ million dollars. Putting the thing in a different way, the gain of valuable metals previously lost in tailings and slag would have been 50,000,000 lb. of copper, nearly 1,000,000 oz. of silver and about 5,000 oz. of gold. Note the coincidence between these figures and those that the Anaconda metallurgists were talking about early in 1914.

The enormous saving is being effected at the cost of about $5,000,000 for new plant. In other words, the outlay of that vast sum of money will be repaid in about eight months.

Whence has this spectacular gain been derived? Primarily, chiefly and naturally from the concentrator. We say naturally, for the art of mechanical concentration has ever been the most imperfect of our metallurgical processes and an attempt to make a big saving was logically directed to that quarter. What has been accomplished there sounds almost fabulous. Formerly the tailings wasted from the mill assayed about 0.62% copper. Now they go only about 0.10%, and there is a reasonable expectation that even that small figure will be bettered. The Anaconda ore fed into the mill contains 60 lb. copper per ton, whereof only 1⅓ lb. now goes away with the tailings. The recovery in milling is therefore $97\frac{3}{4}$%. Nothing like that in mechanical concentration was ever heard of before. The statement that about two-thirds of the net annual saving will be made in the concentrator is therefore immediately comprehensible.

The other great items of saving are: (1) The improvement of the reverberatory-smelting process by the introduction of coal-dust firing—the daily furnace duty being 583 tons against a former 239 tons and the ratio of ore to coal being 6.95:1 against a former 3.96:1, besides which there is a reduction of the copper loss in the slag; (2) the abandonment of briquetting and blast-furnace smelting in favor of the new reverberatory process; (3) the saving in freight resulting from the direction of all the concentrating ore to Anaconda instead of sending some of it to Great Falls; and (4) the operation of the leaching plant.

Not the least remarkable thing in this great transformation was the skill with which everything was done without interfering with production, there having been no general shutdown of the plant, no diminution of the regular output. The alteration of the concentrator was done section by section, and so efficiently was this managed that the time of changing a section from the old style to the new was only 26 days.

Even before these changes at Anaconda were conceived, the metallurgical practice there ranked with the best in America and the improvement of it might have been regarded as an attempt to burnish fine gold. Anyway, most metallurgists would have been satisfied with what they were doing and would have waited until the prodding of competition forced them to think. Not so with the Anaconda staff. It will now have the satisfaction of knowing that it has won the greatest triumph in the annals of copper metallurgy and has put the Anaconda company into the ranks of the low-cost producers of copper.

Revision of the Mining Laws

Much interest is being manifested in the meeting of mining men to be held in Washington Dec. 16 under the auspices of the Mining and Metallurgical Society of America. Delegates from all parts of the United States have already signified their intention to be present. It is

hoped that the attendance will be large and representative.

The purpose of this meeting is to demonstrate to Congress that the men who are engaged in the mining industry of the United States want a reform of the archaic and discordant mining laws under which they have been operating for the last 50 years. That a reform is wanted by a great majority is undubted. To be sure, there are some who say that the mining industry has thriven under the existing system and therefore it should be let alone, but the answer to this is that it has thriven in spite of the system and in most of our great mining camps the extralateral features of the law have been abolished by common consent, as also has been the requirement of discovery.

However, the purpose of the forthcoming meeting, as stated by the Mining and Metallurgical Society, is not to advocate specific reforms, not to attempt to draft a new law in convention, but to impress upon Congress the demand of the industry that something be done. The drafting of a new law ought to be the work of a commission, which will study the diverse conditions of our mineral deposits, hear the opinions of a great many people and coördinate everything for the general good.

This was recognized in bills that were introduced in the Senate and the House respectively last winter, largely through the instrumentality of the American Mining Congress. These bills were pushed far enough to have them reported out of committee, but amid the pressure of other business they failed of passage. The object of the forthcoming meeting is to give one of them, or an improved bill, the effective push that will set it rolling through the next session of Congress right into the President's office for signature.

Anaconda Produces Spelter

The Anaconda company is already turning out electrolytic zinc at the rate of 10 tons or so per day and is reported to be contemplating the erection of a great plant for this purpose at Great Falls, Mont., or some other place near hydro-electric power supply. Its initial production arrived at a happy time, the price for all spelters being phenomenally high, while high-grade spelter rivals tin in price.

The production of electrolytic spelter on a large scale has not been profitable heretofore. It may fall to the lot of the Anaconda company to tell a different story. There are several important things in its favor. The Butte zinc ore is of a character that permits a high extraction of zinc by sulphuric-acid lixiviation, the formation of zinc ferrite during the roasting being but slight. The ore is relatively high in silver, a large proportion of which is recoverable. Great Falls and other places on the Missouri River afford cheap electric power, which is produced by an allied company. Finally, the process is being developed at a time when profits are so big that they dwarf all infantile discouragements.

It will be interesting to find out what the Anaconda electrolytic spelter is going to run when the process is perfected. The electrolytic spelter produced by Brunner, Mond & Co. at Winnington, England—heretofore the only supply of this sort—is guaranteed 99.95% Zn. Using the relatively pure ore of Butte, Anaconda should be able to do as well, and probably will.

It is worth while to note that electrolytic spelter is now being produced at the rate of several tons daily by the Weedon Mining Co. at Welland, Ont., and some is also being produced by the Consolidated Mining and Smelting Co. at Trail, B. C. The Bully Hill Copper Co. in California has been working on this subject for a long time, and it also may become a regular producer ere long.

High-Grade Spelter

Previous to the war there was an official classification of virgin spelter as high-grade, intermediate, brass special and prime Western. High-grade spelter had to contain at least 99.9% zinc and intermediate from 99.5 to 99.9%, besides conforming to certain specifications respecting the contents of lead, iron and cadmium. The only high-grade spelter was the well-known Horsehead and Bertha brands, and there was but a limited market for them. By restricting the production to the relatively small demand a premium of about 2½c. per lb. was realized for these brands on the average.

Soon after the war began, an extraordinary demand for spelter of this kind arose, and in 1915 a price as high as 40c. per lb. was received, which was about 15c. per lb. above the maximum for prime Western. The classification of intermediate spelter was practically wiped out, a range of 0.5% in zinc content being too wide. Spelter assaying 99.8 to 99.9% zinc fetched one price, that assaying 99.7 to 99.8 another, and so on. In fact, there developed a market for high-grade spelter, for high-grade intermediate, for lower grades of intermediate and thus downward. Until recently the Horsehead and Bertha brands continued to be the only high-grade spelter, strictly speaking, although the high-grade intermediate was commonly referred to as such. Lately the Mascot brand, produced from Tennessee ore, has been put in the high-grade class by refinement of methods of production.

The high-grade intermediate spelter is produced by the smelting of ore selected for its purity—especially its freedom from lead—or by the redistillation of common spelter. In either case the impurity that is particularly difficult to control is cadmium. Most of the spelters that analyze about 99.85% in zinc are equal to the high-grade specifications in the matters of lead and iron, but are a little too high in cadmium.

Now whether cadmium is a deleterious element in spelter, or not, is a moot point, even with regard to a considerable proportion of it. For many purposes—even military purposes—it is inconceivable that 0.05% Cd, plus or minus, can make any great difference. Readers of the *Journal* may recollect a discussion of the subject of cadmium in spelter in these pages about 10 years ago, when some manufacturing experiments made by a well-known brass maker were referred to and the deduction was drawn that for ordinary brass cadmium is not a deleterious element. Since then Mr. Rigg and his colleagues in the New Jersey Zinc Co. have indisputably shown that cadmium—even in small proportion—is highly objectionable in spelter that is to be used for making slush castings. It is pretty well established, moreover, that for making cartridge brass the spelter should be as pure as can be obtained, for otherwise the cartridge cases deteriorate in course of time. The quality of the brass

is not apparently so important in the case of cartridges that are to be used soon.

Let the influence of cadmium in spelter be what it may, there is no doubt that military specifications have called for spelter much more highly refined than is necessary in many cases. However, discussion of this is purely academic. Some users of spelter have cadmium on the brain and are willing to pay 5c. or so per lb. of spelter for the difference between 0.1% Cd and 0.05% Cd, and the rational thing for zinc producers to do is to give them what they want and take their money. There is no use in arguing with them that they ought not to want what they think they do.

Whether it be high-grade spelter or high-grade intermediate, the preposterous premium had the natural effect of stimulating the production of those kinds, and of course, the additional supply will sooner or later reduce the premium. Of late these sorts of spelter have not been so readily salable as they were a little while ago. Some of the producers, averse to recognizing any change in the conditions and hopeful that they will once more be able to sell their product at the price for tin, are holding it back. Such accumulation of unsold spelter as is now believed to be taking place is supposed to be chiefly of these kinds. One of the reasons for the sustained strength in the market for prime Western is the diversion of so large a proportion of it to the manufacture of refined. The advent of new producers of superior spelter will naturally hasten the correction of the disparity in prices that has existed for so many months.

⁂

Anti-Alien Laws Declared Unconstitutional

The Supreme Court of the United States decided last week that the Arizona Anti-Alien Labor Law is unconstitutional. This is the law passed recently in Arizona, which prohibits employers of labor from having among their employees more than 20% of persons not citizens of the United States. The Supreme Court decided that it is in contravention of the Fourteenth Amendment. How emphatic is the stand of the court is shown by the following from Justice Hughes' opinion:

> It requires no argument to show that the right to work for a living in the common occupations of the community is of the very essence of the personal freedom and opportunity that it was the purpose of the Fourteenth Amendment to secure. If this could be refused solely upon the ground of race or nationality the prohibition of the denial to any person of the equal protection of the laws would be a barren form of words.

If the Arizona Anti-Alien Law had been upheld, the effect upon the mining companies of that state would have been very serious. However, nobody was ever much worried about it, the intelligent opinion having been from the beginning that the law was unconstitutional and would be nullified by the Supreme Court.

⁂

The Department of Justice has appealed to the Supreme Court in the case of the United States Steel Corporation. It thinks that the Circuit Court was mistaken in the decision that the Steel Corporation is not a combination in restraint of trade; also in the decisions respecting other matters. In the meanwhile the Department of Justice is alleged to be looking with suspicious eyes upon the Bethlehem Steel Co., Pennsylvania Steel Co., Cambria Steel Co., etc., among which one or two combinations are supposed to be impending. These companies are believed to have become so big and prosperous that the public may have to be protected against them. This notion does not, however, harmonize with the idea still entertained regarding the Steel Corporation.

BY THE WAY

The *Wall Street Journal* recently commented on the alleged ability of the ground hog to foretell an early or late spring on his first emergence from winter retirement and opines that Wall Street is not without its ground hog. This sagacious animal, resident in Massachusetts, comes out of its burrow from time to time and looks over the financial sky, eventually making a noise which sounds like "coppers." When this noise is heard one may know that a bull market is nearly over. The animal's name is supposed to be thomaswlawson.

⁂

The sixth arrest in the alleged plot to dynamite ships leaving New York with munitions for the Allies was made on Nov. 1. The last prisoner is stated to be "Engelbert Bronkhurst, mining engineer and explosives expert." According to the reporters he is 52 years old, speaks seven languages, and is the most striking looking person in the alleged conspiracy. He was born in Hanover, Germany; won a degree in mining engineering; served in the army; worked in the South African diamond mines; came to this country and worked in the mines in the West and Southwest, and spent several years in South America.

⁂

In the good old days of 25 years ago, in order to attract money into an alleged gold mine it was only necessary to display a truck load of the quartz in some City shop window, according to the London *Financial News*. Gaping crowds gathered around, feasted their eyes upon the unwonted sight and then hurried off to apply for shares. In one case, the *News* continues, a truck load of quartz had been utilized in this way and there was an overwhelming subscription for the shares. The amateur board of directors wished to justify its existence and immediately after allotment cabled the manager to commence crushing. He replied, also by cable, that he could not commence crushing until the reef was sent back to him from London.

⁂

General Francisco Villa, according to the New York *Times* of Nov. 1, arrived at the international border, and announced that he intended to attack the Mexican town of Agua Prieta regardless of any action United States troops might take. "If necessary I will fight the United States army assembled along the border," he said. When he learned that General Carranza had been permitted to transport reinforcements over American territory he said: "This is the way the United States repays me for the treatment and protection I have given foreigners in Mexico. Hereafter I don't give a —— what happens to foreigners in Mexico or in my territory. I am through with the United States. I can fight my battles. Let them fight theirs. I can whip Carranza and his entire army, but it is asking a great deal to whip the United States also, but I suppose I can do that, too." Hully gee!

Accidents in Metallurgical Plants in 1913 and 1914

The first report of the United States Bureau of Mines on accidents at metallurgical works has just been issued by the bureau and includes the calendar years 1913 and 1914. The figures, compiled by Albert H. Fay, engineer, show that 119 men were killed during the two years, 2,285 seriously injured and 11,046 slightly injured at smelting plants and mills, representing fatality and injury rates of 1.55, 29.67 and 143.44 respectively per 1,000 men employed per year. The report includes the returns of 79 smelting plants in 1913 and 94 in 1914, including copper, lead and zinc, and quicksilver smelteries, as well as refineries. The iron blast-furnace figures are not included. The number of ore-dressing plants in 1913 was 311 and in 1914, 484. These represent concentrating plants of copper, lead and zinc ores, stamp mills, cyanide plants and iron-ore washers.

The total number of men employed in the metallurgical plants cited, both smelteries and ore-dressing plants, was 35,549 in 1913 and 41,461 in 1914.

In the ore-dressing plants machinery was responsible for 25.6% of all fatalities, 28.9% of the serious injuries and 16.5% of the slight injuries. Similar figures for smelting plants are much smaller, for the reason that there is more machinery in use in ore-dressing plants than in smelteries, and the men are usually in closer contact with the machinery; as, for example, at jigs, tables, stamps, rolls, and crushers. There are many revolving shafts, a large number of which have projecting keys, moving belts, wheels and cams within the reach of the operator. The machinery at smelting plants is usually confined to the power house, where the blowers, engines and dynamos are placed, and to overhead cranes, most all of which are entirely out of the reach of the regular employees.

The percentage of accidents caused by "falls of persons" and "flying and falling objects" is 15.4% apiece in ore-dressing plants, whereas at the smelteries the fatalities due to falls of persons represent 20% of the total and those due to flying or falling objects represent 5%.

Haulage systems claim 25% of the fatalities at smelting plants and about half this percentage at ore-dressing plants. The difference is due largely to the type of material handled and to the greater number of cars in operation around smeltery yards than at ore-dressing plants. In many ore-dressing plants the ore is brought to the bins in railroad cars or aërial trams, and often there is no other haulage system in connection with the plants, the tailings usually being disposed of by launders or flumes; whereas at smelting plants the molten slag is handled in slag cars and the bullion has to be handled on trucks.

At smelting plants burns from hot metal, slag, etc., claim the largest percentage of serious and slight injuries and 11.3% of the fatalities.

The tables presented will serve to call attention to the principal causes of accidents at these works and should serve as guides for the safety engineer to show where it will be possible for him to do his work most efficiently and to accomplish the best results. Little has been written on the subject of metallurgical accidents, other than for the iron and steel industry, and statistical information is far from being complete. Certainly the above figures can be bettered. One man injured in every seven employed each year is too high.

NEW PATENTS

United States patent specifications listed below may be obtained from "The Engineering and Mining Journal" at 25c. each. British patents are supplied at 40c. each.

LABORATORY TABLE. Emil W. Schmeling, Rockford, Ill. (U. S. No. 1,158,305; Oct. 26, 1915.)

LADLES—Improvements in Nozzles and Stoppers for Steel Ladles and the Like Appliances Connected Therewith. P. W. Fawcett and F. Batty, Sheffield, Eng. (Brit. No. 22,746 of 1914.)

LEAD—Machine for Casting Lead Pigs. John Forsyth Miller, Trail, B. C. (U. S. No. 1,157,794; Oct. 26, 1915.)

LEAD AND ZINC—Process for the Industrial Separation of Lead and Zinc Contained in the State of Sulphides in Ores. Guy de Bechi, London, England. (U. S. No. 1,157,153; Oct. 19, 1915.)

METAL COATING—Method of Melting and Spraying Fusible Substances. Franz Herkenrath, Zurich, Switzerland, assignor, by mesne assignments, to Metals Coating Co., of America, Boston, Mass. (U. S. No. 1,157,984; Oct. 26, 1915.)

METAL RECOVERY—Improved Process of Recovering Metals From Ores. New Metals Process Co., Chicago, Ill. (Brit. No. 17,324 of 1914.)

MINE-CAR BRAKE. Henry Dow Scott, Sheridan, Wyo. (U. S. No. 1,155,864; Oct. 5, 1915.)

MINE TAILINGS—Slime Thickener for Dewatering Mine Tailings. Wilton E. Darrow, Sutter Creek, Calif. (U. S. No. 1,156,276; Oct. 12, 1915.)

POTASH—Process of Recovering Potash. Arthur C. Spencer, Washington, D. C. (U. S. No. 1,157,437; Oct. 19, 1915.)

POWDERED FUEL—Engine for Utilizing Powdered Fuel. William G. Miner, Cincinnati, Ohio. (U. S. No. 1,156,702; Oct. 12, 1915.)

RADIUM—Process of Concentrating Radium Ores and Residues. Otto Paul Curt Bredt, New York, N. Y., assignor of three-fifths to Radium Therapy Corporation, New York, N. Y. (U. S. No. 1,154,231; Sept. 21, 1915.)

SEPARATION—An Improvement in the Magnetic Separation of Ores. G. B. Schwerin, Frankfurt a. Main, Germany. (Brit. No. 19,313 of 1914.)

SEPARATION—Improvements in Ore-Separating Machines. H. H. Thompson Aldridge, and A. E. Davies, Hockley Heath, Warwick, Eng. (Brit. No. 21,119 of 1914.)

SEPARATOR—Magnetic Ore Separator. August F. Jobke, Wilkinsburg, Penn., assignor of one-half to John G. Burns, Daniel Bingham, Katherine Crumay, Thomas Higgins, and H. P. Gazzam, Pittsburgh, Penn. (U. S. No. 1,157,543; Oct. 19, 1915.)

STEEL—Improvements in or Relating to the Treatment of Steel. A. Hethy, London, Eng. (Brit. No. 17,285 of 1914.)

STEEL—Manufacture of Steel. Jegor Israel Bronn, Rombach, Germany, assignor of one-half to the Firm of Rombacher Hüttenwerke, Rombach, Germany. (U. S. No. 1,156,051; Oct. 12, 1915.)

STEEL—Manufacture of Steel. William R. Walker, New York, N. Y. (U. S. No. 1,155,849; Oct. 5, 1915.)

SULPHURIC ACID—Method of Making Sulphuric Acid. Edwin Taylor, New York, and Frederick P. Bergh, Yonkers, N. Y. (U. S. No. 1,157,455; Oct. 19, 1915.)

TANKS—Lining for Tanks. Thomas E. Murray, New York, N. Y. (U. S. No. 1,156,425; Oct. 12, 1915.)

TIN—Detinning Tin Scrap. Karl Goldschmidt and Josef Weber, Essen-on-the-Ruhr, Germany, assignors, by mesne assignments, to Goldschmidt Detinning Co., Jersey City, N. J. (U. S. No. 1,158,128; Oct. 26, 1915.)

TIN—Electrolytic Refining of Tin. Robert L. Whitehead, Perth Amboy, N. J., assignor to American Smelting and Refining Co., Maurer, N. J. (U. S. No. 1,157,830; Oct. 26, 1915.)

TITANIUM—Composite Titanic-Oxide Pigment and Method of Producing Same. Louis E. Barton, Niagara Falls, N. Y., assignor to the Titanium Alloy Manufacturing Co., New York, N. Y. (U. S. No. 1,155,462; Oct. 5, 1915.)

TITANIUM—Process of Producing Titanium-Oxygen Compounds from Ilmenite or Titaniferous Iron Ores and Other Materials. Peder Farup, Trondhjem, Norway. (U. S. No. 1,156,220; Oct. 12, 1915.)

TUBE MILL. William Fennell, Southam, near Rugby, England. (U. S. Nos. 1,154,981 and 1,154,982; Sept. 28, 1915.)

TUNNELING—Method of and Apparatus for Tunnel Work. Edward G. Williams and Elmer H. Brown, Washington, D. C. (U. S. No. 1,156,830; Oct. 12, 1915.)

TUNNELING MACHINE. William E. Dean, Superior, Wis. (U. S. No. 1,156,277; Oct. 12, 1915.)

ZINC—Extraction, Purification, and Electrolytic Precipitation of Metallic Zinc from Smelter Fumes, Zinc Ores and the Like. Otto Best, San Francisco, Calif. (U. S. No. 1,151,601; Sept. 28, 1915.)

ZINC—Hydrometallurgy of Zinc. Otto Best, San Francisco, Calif. (U. S. No. 1,154,602; Sept. 28, 1915.)

ZINC—Improved Process for the Production in a Closed Cycle of Pure Carbonate of Zinc. E. Hunebelle, Paris, France. (Brit. No. 14,226 of 1914.)

ZINC—Process for the Manufacture of Spelter from Ferruginous and Admixed Zinc-Blende Ores. John James Fingland, Kaslo, B. C. (U. S. No. 1,157,375; Oct. 19, 1915.)

ZINC—Process of Smelting Zinc. Samuel Peacock, Philadelphia, Penn., assignor by mesne assignments to Agricultural Research Corporation, New York, N. Y. (U. S. No. 1,154,892; Sept. 28, 1915.)

PERSONALS

Thomas F. Cole, of Duluth, Minn., is in New York.

Walter G. Perkins, of London, is visiting New York.

Frank M. Murphy, of Prescott, Ariz., is visiting New York.

Thomas Robins is secretary of the Naval Consulting Board.

E. V. Newlands, of Toronto, Ont., has gone to British Guiana.

W. L. Saunders is second vice-chairman of the Naval Consulting Board.

Dr. L. D. Ricketts is to be the next president of the American Institute of Mining Engineers.

H. C. Hoover, who has been paying a brief visit to New York, returned to London this week.

Edmund Putnam, formerly operating at Parral, Chihuahua, Mexico, is at present in New York.

Robert Forbes, of Duluth, Minn., who is operating copper properties on Texada Island, B. C., is in New York.

F. W. Bosco has returned to Denver from a six-weeks' engagement at the Victory mine near Boise, Idaho.

Charles J. Curtin, of Brockville, Ont., is superintendent of the Kingdom lead mine at Galetta, near Arnprior.

E. Jacobs, of Victoria, B. C., is traveling through the Kootenay and Boundary districts of British Columbia.

E. B. Bronson has returned to New York from a trip to the Atlanta, Home and Calaveras properties in Nevada.

James Myers, superintendent of the Wanakah smeltery at Ouray, Colo., has resumed duties after a short illness at Golden.

Dr. T. L. Walker, of the University of Toronto, has been chosen chairman of Toronto Branch of the Canadian Mining Institute.

Robert L. Willis has been appointed steam and efficiency engineer of the Republic Steel and Iron Co., with office at Youngstown, Ohio.

Alvin R. Kenner, general superintendent of the Rio Plata Mining Co., has returned to El Paso, Texas, after spending two weeks in New York.

Mototaro Ogino, manager of the Osaka office of Furukawa & Co., of Tokyo, Japan, visited New York last week on his way from London to Japan.

Robert Marsh, Jr., of New York, has been appointed general superintendent of mines for the Nevada Consolidated Copper Co., at Ruth, Nevada.

E. J. Rogers, superintendent of the Omaha & Grant smeltery, Denver, until it was closed down, celebrated his golden wedding in Denver, Nov. 1. Shippers of ore to this once famous plant knew him well.

William D. Stevens, mining engineer and son of the late Horace J. Stevens, is reported lost in the swamp 10 miles south of Houghton, Mich. He was one of a party of seven, six of whom have found their way out.

William C. Russell, mining engineer, formerly of Denver, Colo., is now in Cardinal, Colo. He has taken the management of the Carriman Mining Co., operating the famous old Caribou property in Boulder County, Colorado.

W. R. Thurston has been appointed manager of the Mine and Smelter Supply Co.'s Salt Lake City branch. F. E. Marcy, former manager, will still be associated with the company and devote his efforts to selling and developing the Marcy ball mill.

OBITUARY

Peter Creek Fernie died recently in Victoria, B. C., aged 84 years. About 1880 he discovered outcrops of coal in the Crow's Nest Pass country, and some years later did further prospecting there, succeeding in forming a company to operate the mines. It was later absorbed by the Crow's Nest Pass Coal Co., of Toronto.

Donald E. K. Rickard, student in the College of Mining, University of California, was fatally injured in an automobile accident, dying on Oct. 23 at Berkeley, Calif. He was 21 years old, native of California, son of the late Thomas Rickard, former mayor of Berkeley, and cousin of T. A. Rickard, editor of the "Mining and Scientific Press."

Col. T. E. Vickers died recently in London, aged 82 years. He came from a family which had been in the steel trade for several generations; he was born in Sheffield and brought up to the trade. Succeeding his father in business, he gradually developed the great firm now known as Vickers, Sons & Maxim, the largest makers of war munitions in England. He was head of the company for a number of years.

Dr. James Caples died at Elk Grove, Sacramento County, Calif., Oct. 24, at the age of 92 years. He was born in Ohio and went to California across the plains in 1849. In 1849 he served as a member of the State Constitutional Convention. His first residence in California was at Hangtown (now Placerville) where he practiced medicine, ran a store and engaged in mining. His wife, to whom he was married 67 years ago, survives.

SOCIETIES

Pan-American Scientific Congress—The Second Congress will be held in Washington, Dec. 27-Jan. 8. The sessions will be held in the building of the Pan-American Union.

American Society of Mechanical Engineers—The annual meeting will be held in New York, Dec. 7-10. Headquarters will be at the Engineering Societies Building.

American Association of Engineers—The first national convention will be held at the Hotel La Salle, Chicago, Dec. 10-11. Arthur Kneisel is secretary, his address being No. 29 South La Salle St., Chicago.

INDUSTRIAL NEWS

A series of three industrial motion-picture films, illustrating the manufacture of "National" pipe, from ore to finished product, will be shown before the National Association of Stationary Engineers, No. 21, Lima, Ohio, Monday night, Nov. 15, 1915.

The exclusive manufacturing and selling rights of the Albrecht excavator and loader have been taken over by the T. L. Smith Co., 1119A 32nd St., Milwaukee, Wis. This machine is described as being halfway between the hand and steam shovel and capable of doing the work of either. Two men are required to operate it, one man in the pit to handle the scraper, and one to run the machine. A 12-hp. gas engine provides power to dig and load 20 cu.yd. per hour.

The Royal Manufacturing Co., of Rahway, N. J., extensive dealer in cotton and woolen waste, is making an attempt to standardize the trade. It has divided its wares into twelve branded grades, of which samples are furnished in a folder. The waste is bought by its branded name, and the packages are guaranteed to contain not over a certain amount of tare and to be of accurate weight, so that the payment for a lot of hoops and bagging at waste prices, or the padding of an order 30 to 50 per cent., is avoided.

Hamilton & Hansell, Whitehall Bldg., New York, report the recent sale of a 4-ton Rennerfelt electric-arc furnace to the Old Dominion Iron and Nail Works Co., Richmond, Va. This furnace will be used to make steel for rolling 2-in. billets. Of other Rennerfelt electric-arc furnaces—34 have been sold—15 are used for making steel for castings, 5 for tool steel, 4 for brass melting, 2 each for chemical purposes and iron castings, and 1 each for nickel, copper and ferromanganese melting. Some of these furnaces, however, are used for more than the one purpose listed.

More than 20 nations are represented by visitors to the United States who are now making their headquarters at the branch offices of the Bureau of Foreign and Domestic Commerce, Department of Commerce, and who are seeking new trade relations. Many of these men are members of foreign firms which are preparing to make purchases here. Others are representatives of big commercial houses and offer unusual facilities for our manufacturers to establish agencies abroad. Their earnest efforts to meet us half-way in producing a greater volume of trade with their respective countries are making easier the progress of American commerce in this year of opportunity. Because of the foreign visitors flocking here, the Bureau is dealing directly with buyers as well as sellers, and bringing both classes of business men together so effectively that there are results—purchases of American goods and the making of contracts for agencies in other countries.

Editorial Correspondence

SAN FRANCISCO—Nov. 3

California Metal Producers Association held its first annual meeting at San Francisco, Oct. 27. Reports from President Albert Burch and Secretary-Treasurer Robert I. Kerr showed that the membership has increased from 22 to 41 and now represents approximately 90% of the aggregate capital invested and 90% of the employment of labor in the metal mines of California. The association has taken an active interest in mining affairs for the betterment of the interests of investors and producers and incidentally to the advantage of employees. The accomplishments of the past year include the reduction of workmen's compensation insurance, which resulted in a saving of many thousands of dollars to all mine operators, and the prevention of legislation detrimental to mine operations. The association also took up the question of mine safety in joint meetings with the State Industrial Accident Commission, with the result that the rules finally adopted by the commission and which become operative under the compensation and insurance act are far more favorable to the satisfactory operation of the mines than would have resulted in the absence of concerted action on the part of owners and operators of metal mines. The association financed the field meets at the Panama-Pacific Exposition in September, and will work for the proposed revision of the national mining laws. The executive board consists of Albert Burch, president; George W. Metcalfe, first vice-president; E. C. Hutchinson, second vice-president and C. E. Knox, George W. Starr, Newton Cleaveland, S. W. Mudd. Finance committee: Louis Rosenfeld, Henry Malloch, William Hauge. Secretary-treasurer Robert I. Kerr, who in the last half of the year succeeded John Mocine, resigned. The association has permanent quarters at 631 Market St., San Francisco.

Ore Transportation from the Ubehebe District, in the northeastern part of Inyo County, will be undertaken with Yuba ball-tread tractors manufactured by Yuba Construction Co., at Marysville. The district lies on the edge of the county, 60 mi. east of Laws, a shipping station on the Southern Pacific and 51 mi. northwest of Bonnie Clare, Nev., a shipping station on the Tonopah & Tidewater R.R. The trial trips of the tractors hauling the ore wagons will be made to the Tonopah & Tidewater. Yuba Construction Co. has placed one of its tractors at the disposal of the mine operators and four ore wagons have been provided for the experiment. F. A. Campbell has undertaken the contract to haul the ore to be furnished by W. W. Waterson, Archie Farrington and others, who agree to furnish 500 tons for a beginning. The road has been examined and is rated fair, with no apparent obstruction to economic operation of the tractor. The Ubehebe district contains many and large veins of copper, lead and silver ores which may be developed and operated only with the aid of economic transportation to shipping points. The district is in the same commercial situation that many other mining districts and camps in California and Nevada occupy, and which must remain undeveloped if they depend upon animal transportation of ores. Motor trucks have been used economically in many districts or camps where the transportation requirements are not large. But in cases of large amounts of ore to be shipped daily, the motor truck is not an economic transport, as a separate truck is required for each load and the labor cost is increased by the necessity of employing a driver for each truck. Another disadvantage of the motor truck is, that unusual grades or pieces of bad road require unloading of part of the ore and making two trips with a load that can be carried on ordinary grades and good roads. The same condition of heavy grades and bad roads must inevitably be met by the tractors, but the necessity of unloading and reloading is avoided by the fact that the tractor hauls the loaded wagons, which may be taken over one at a time, but carries no load on its own wheels except its engine and essential machinery and driver. The Yuba tractors are of the caterpillar type, but are light and capable of being turned in narrow roads at sharper angles than the usual type of motor truck, which must of necessity carry its load above its driving machinery and running gear, making it top heavy and unsafe on narrow roads and difficult grades. However, there are conditions in the mining districts of California and Nevada which are ideal for the motor truck method of transportation, which render the caterpillar type of transport unsatisfactory for economic ore hauling. Both methods are available under conditions suited to their respective advantages and both are gradually displacing the animal hauling and making possible the economic transportation of ores from any district where horses or mules can travel with wagons.

DENVER—Nov. 4

Colorado Fuel and Iron Co. is investigating two deposits of iron ore in Wyoming—the Popo Agie tract, 12 miles from Lander, and the Welsh tract, 19 miles from the same railroad point. Should these deposits prove of proper grade and size, company may erect a blast furnace at some central point for treating the ore from these properties as well as from the mines at Sunrise, Guernsey and Hartville.

Radium-Bearing Lands in Colorado are again in the limelight. Thomas R. Henahan, formerly Colorado's commissioner of mines and now retained by the Standard Chemical Co., after a thorough personal investigation of the radium-bearing lands in western Colorado and eastern Utah, has written an open letter to Secretary of the Interior Franklin K. Lane, strenuously opposing the proposed withdrawal of such mineral lands from public entry and making caustic criticism of statements made by Bureau of Mines experts. He contradicts the statement that these fields will supply radium for a few years only and expresses the belief that none of the experts has been 10 miles away from an automobile road while making his investigations.

BUTTE—Nov. 4

Suits Resulting from Butte's Street Riots of last year are now being heard. On Nov. 1, Judge Lynch sustained the demurrer entered by the City of Butte to the complaint of the Butte Miners' Union, which has filed a suit against the city for $140,000 damages to Union property during last year's rioting. The demurrer set up that the complaint was not sufficiently definite to constitute cause of action. Attorney for old union was allowed 20 days in which to file amended complaint. Arguing in support of sufficiency of the complaint Attorney Breen for the union alleged that mob which blew up the union hall was not restrained by policemen who had been held in reserve and that therefore liability for destruction of property fell on city which did not use its police powers. The suit brought by Charles H. Moyer and trustees of Western Federation of Miners against the Butte Miners' Union will be heard in the Federal court, according to decision handed down Oct. 28 by Judge Bourquin. Court denied motion to dismiss action. Suit was brought to get possession of property of Butte Miners' Union.

SALT LAKE CITY—Nov. 5

In the Tintic District, several new roads have been built, or are to be built. The Chief Consolidated has completed its road from the Scotia mine in West Tintic to Jericho on the Salt Lake route, and ore hauling by traction engine and trailers will begin shortly. A new wagon road is to be built between Tintic Junction and Eureka; also one south from Silver City to connect with the Millard County road near Lynn Junction.

The Strike at the Silver King Coalition in Park City is still undecided. The miners have been addressed by Thomas Kearns, general manager, who stated the company's position. About 200 men met in Park City and voted to stay out indefinitely, or until some change is shown by the management in regard to the hospital question. A few men returned to work Nov. 4, and are employed about the mill in the installation of the flotation plant. Others who have been in favor of returning to work, were kept from doing so by fear. There are 34 deputy sheriffs at the mine under Sheriff Ryan, although no violence is expected. It is thought that both sides will refuse to yield and that ultimately the company will bring in outside men.

SEATTLE—Nov. 3

A Deposit of Chromic Iron has been found in Alaska at the head of a small bay on the peninsula between Seldovia and Dick's Bay. It is about eight miles from tidewater and a valley provides easy means of transportation for ores to the beach. The deposit has been known to miners for the last year but the extent of the orebodies was not determined until recently. It is now reported to be over one mile wide and

several miles long. The contact is very marked. Vegetation grows luxuriantly up to the change in formation where the surface then assumes a dull yellow. The peculiar color of the mountain is due to the leaching. Below the surface the ore is black. A little development work has been done on some of the Elizabeth group of islands lying off the main body in the bay. The discovery is hailed by mining operators in the north as one of the most important made in recent years as chromite is in great demand.

Wood in the Fairbanks Mining District is getting to be classed as jewelry. Twenty dollars a cord is the highest price so far, but it is still going up. In the Nenana coal field, about 100 mi. from Fairbanks, are vast beds of lignite coal, which will be available as soon as some method of transportation is provided. It is expected that a railroad to these coal fields from Fairbanks, even before the trunk line is completed, will greatly increase quartz mining activity in that district. With coal available for fuel, large areas of low-grade auriferons gravel, which cannot be worked with fuel ranging from $10 to $20 a cord, will become productive, and the placer gold output will be largely increased, if not doubled. Quartz mining and milling is an established industry in which only high-grade ores can be worked with a profit, owing to the high fuel charges. Congress, which is about to meet, will be asked to appropriate money to enable the Alaska Engineering Commission to carry on its work of constructing a railroad from Seward to Fairbanks. The Fairbanks people are behind a get-together movement to push this thing, in order to get coal into the Fairbanks district.

WALLACE, IDA.—Nov. 4

The Bunker Hill & Sullivan company has made no definite announcement regarding the situation the smelter it is preparing to build, but indications clearly point to Kellogg as the place. Easements which will secure the company against possible damages from smoke have been secured in most of the land that would possibly be affected, and Mr. LaBarthe, of the engineering firm which will design the plant, has been on the ground for several weeks working out the preliminary details. The talk of tronble with the American Smelting and Refining Co., which has a contract with the Bunker Hill & Sullivan company covering a period of 15 years, was silenced a few days ago when Stanly A. Easton, manager of the Bunker Hill & Sullivan company, stated that the A. S. & R. company could no more stop the Bunker Hill from smelting its own ore than it could prevent it from concentrating it. Mr. Easton also stated that the proposed plant would be in position to handle the ores of other lead mines, an announcement that has been received with much satisfaction here, as a local plant will certainly be highly beneficial to the mining industry. It was rumored during the week that representatives of other large smelter interests which are supposed to have an unwritten agreement with the A. S. & R., have been in the district recently prepared to offer concessions to the Bunker Hill in the hope of getting the company to abandon the smelter plan, but there is no evidence that these efforts if made have met with encouragement.

In Securing Control of the Ray-Jefferson the Day family is about to embark in zinc mining in addition to its extensive operations in lead. The Ray-Jefferson owns 32 claims, with mill site and water rights, on Beaver Creek, and extensive development has disclosed large bodies of zinc and considerable lead. The property joins the Interstate-Callahan on the west and is supposed to have the extension of zinc oreshoot from which property has paid nearly $2,000,000 in dividends during the past year. A few weeks ago when the announcement was made that the Ray-Jefferson had been financed to the extent of $200,000 which would insure its further development and the erection of a 250-ton mill in the spring, it was known that the financial support had come from the Days, who were already quite heavy stockholders in the company. A meeting of the directors of the Ray-Jefferson recently submitted a proposition to the stockholders to increase the capital stock of the company from 1,500,000 shares to 2,000,000, and the stockholders will meet on Nov. 6 in this city to take action. There is no doubt that the proposition will carry, and it is understood that the additional stock will go to the Days in return for the cash they have agreed to advance. This with their present holdings and other stock that is friendly to them will make them the controlling factor. In this connection the attitude of the Interstate-Callahan company is of more than passing interest. Several months ago this company made overtures for the purchase of the Ray-Jefferson, but without success. These were renewed recently and are now being pressed, the figure being offered individnal stockholders being on a basis of near $1,000,000 for the property. The anxiety of the Interstate-Callahan people to secure the Ray-Jefferson is not due wholly to the probability that its orebodies extend into the Ray-Jefferson gronnd. Another reason of even greater importance is believed to have been disclosed in the action of the Callahan-Boutin faction of the Interstate-Callahan about a month ago in applying to the district court here for the appointment of a receiver to take charge of the company's property, and the appointment of Eugene R. Day, manager of the Hercules mine, receiver. This action was blocked by the Percival-Robbers faction, which is in control of the property, which succeeded in having the application for a receiver transferred to the federal court, where it is now pending. It now appears that the Interstate-Callahan company, as represented by the Percival-Robbers element, has discovered in this action to throw the property into the hands of a receiver, and particularly in the appointment of Mr. Day, the first step in a scheme to dissolve or unconsolidate the Consolidated Interstate-Callahan Mining Co. with the ultimate purpose in view of consolidating the Callahan with the Ray-Jefferson and leaving the Interstate to hold the bag, so to speak, as it is known that the big end of the orebodies of the consolidated property is in the Callahan ground. With the Days in control of the Ray-Jefferson and the possibility of the Interstate-Callahan company being thrown into the hands of a receiver, the men who exercise control of the big zinc producer are evidently acting upon the belief that the acquisition of the Ray-Jefferson is as necessary for the security of their present holdings as it is for its additional ore reserves.

MORENCI, ARIZ.—Nov. 5

The Western Federation has tightened the censorship in the Clifton-Morenci-Metcalf strike district. One's comings and goings are investigated closely, and woe unto him whose passport is found wanting. It is said nobody can leave camp with a ticket that reads to Duncan, where the companies have established a tent colony to accommodate such apostates as have seen the error of their way and wish to return to the good graces of the company that has given them an opportunity to earn a goodly livelihood these 20 years. All persons arriving in the district are closely interrogated as to their business, length of sojourn, etc. About 2,000 men met the train at Clifton Nov. 1, and made a public bonfire of copies of the El Paso "Morning Times," which paper is barred from the district. Governor Hunt has headed a public subscription with $500 and asks all citizens to follow suit with a donation for strikers, and the federation has assessed every member in the state from $1 to $2 a month, according to his wage. Cyclone Davis, Congressman from Texas, offers his oratorical assistanee to Hunt in fighting the recall petition.

TORONTO—Nov. 6

An Engineer of the Provincial Hydro-Electric Commission, at the request of a nnmber of the mine managers in Cobalt and Porenpine, is making a survey of the power conditions in these two camps and in Sudbury. It is the belief of a number of those interested in mining in northern Ontario that the cost of electric power is much higher than is warranted by conditions. The conditions at Sudbury will not enter very largely into the matter as the plants there are owned largely by the operating companies, but it will give them a basis for comparison of costs with Cobalt and Porcupine. While it is very unlikely that the Hydro-Commission will build in northern Ontario, it may be able to help the mines to obtain lower rates.

VICTORIA, B. C.—Nov. 1

A Rich Strike of Placer Gold has been made on Rnde Creek, a tributary of the Klotosson River, and a stampede is now on for that district, according to Commissioner George Black, head of the government in the Yukon Territory who, on his way out, met as many as 150 men on their way in to the new field. The discovery of placer gold was made in September by Jens Rnde and his partner, two prospectors. The creek has been named Rude Creek. The sand and gravel of the creek has yielded $1.50 per sq.ft. to a depth of 6 ft. The prospectors brought out 50 oz. in gold at the time they staked their elaims. It has been the policy of the Yukon Government to assist the prospectors by furnishing them with free transportation when they have a grubstake sufficient to last them a year. Jens Rude and his partner were two of these prospectors who were thus assisted. They went over the waters of the Yukon, up the White River to the Klotosson River. The government is gratified to see that their efforts in assisting the prospector have met with such success. The point where the gold was discovered is 30 mi. from navigation on the Yukon. The government is cutting a trail in for the accommodation of the miners. Little work can be done this year owing to the lateness of the season when the discovery was made. The men are going in, however, to stake their claims and get ready for operations in the spring. The discoverers are allowed to stake 1,500 ft. along the stream and 1,000 ft. on each side. Those who come after are allowed to stake 500 ft. along the stream, by 2,000 ft. in width.

The Mining News

ALASKA

OUTPUT FOR THE CHISANA DISTRICT is estimated for the year at about $150,000. The mining season has closed there. Some good prospects were found just before the ground froze on Beaver Creek.

GRANITE (Port Wells)—Ore struck at 350-ft. level, through raise from lower adit.

ALASKA MEXICAN (Treadwell)—In September, mill crushed 18,690 tons, yielding $1.42 per ton; net profit, $2,342.

ALASKA TREADWELL (Treadwell)—In September, mills crushed 80,472 tons, yielding $148,842, or $1.87 per ton; operating profit, $60,590; net profit, $52,660.

ALASKA UNITED (Treadwell)—In September, Ready Bullion and 700-Ft. Claim mills crushed 20,104 and 22,890 tons respectively, yielding $1.91 and $1.35 per ton; net profits, $3,022 and $933.

EILDAGO-ALASKA COPPER (Valdez)—Supt. E. D. Reiter states that development will continue throughout the winter and more equipment will be installed next spring. Ore encountered in main raise.

WELSH (Knights Island)—H. C. Vance, who is developing a copper mine at Bay of Isles on Knights Island for Martin Welsh, of Spokane, reports that shaft has encountered ore carrying 10% copper. Plans for wharf for deep-water ships are ready and an adit will be started this winter.

ALASKA MINES EXPLORATION (Seward)—J. H. Sears, Jas. McCoy and Roy D. Fonda have filed articles of incorporation for above company at Juneau. Sears is president of Seward branch of Harriman Bank, and connected with that banking concern at its New York address. Purpose of new company to examine, develop and operate mines in Alaska.

GUGGENHEIM DREDGE (Ruby)—About 400 tons of machinery are being shipped by Guggenheim interests from Dawson to Ruby, where the new dredge will be assembled on ground recently acquired. Active operations on one of the largest dredging propositions ever started in the North will be undertaken next spring.

CLIFF LITIGATION (Valdez)—In the suit brought by Edmund Smith, George Treat and L. Archibald against H. E. Ellis for their claimed interest in the famous Cliff property, the decision in the district court gave Treat a one-tenth interest and the remaining claimants divide a tenth interest. Ellis is working the property and it promises to become a producer again.

ARIZONA

Greenlee County

ARIZONA COPPER (Clifton)—The concentrator at Clifton was burned on the night of Nov. 5. This is the No. 4 mill which was recently remodeled and enlarged to treat 500 tons daily.

Mohave County

UNITED EASTERN (Oatman)—Managing director George Long quoted as stating machinery ordered for 200-ton mill. Also installing extensive mining equipment.

CALIFORNIA

Amador County

LUDEKENS (Pine Grove)—Application made to California Débris Commission to operate by hydraulic process and impound tailings in Grass Valley Creek, draining into Mokelumne River, to be heard at San Francisco, Nov. 15.

ORIGINAL AMADOR (Amador City)—Shaft will be deepened and new levels run for development of orebody below present workings. Extraction of ore will be reduced, but 10 stamps will be kept dropping while sinking is in progress. T. S. O'Brien is manager.

Calaveras County

ASBESTOS DEPOSITS near Copperopolis reported to be in preparation for development and operation. Product will be used for manufacture of fireproof plaster. Fiber is not equal to demand for usual commercial asbestos. Ten men are now employed and number will be increased as work requires.

Eldorado County

DREDGING GROUND on south fork American River near Coloma is being prospected with No. 3 Keystone drill by J. H. Mulloch of San Francisco, who has bonded ground. This is neighborhood in which gold was discovered by Marshall causing first gold rush to California. Reported that W. R. Bell is also interested in bonding other ground in this vicinity, and that installation of California type dredges is probable.

GRIZZLY FLATS (Grizzly Flats)—Property embracing about 140 acres taken over by Los Angeles men. Tunnel is being repaired and timbers cut in preparation for extensive development. Installation of 10-stamp mill contemplated. Deposit contains cemented gravel.

Inyo County

BUNKER HILL (White Mountain District)—S. T. Paul and Tex Hall are investigating property with probable view of taking purchase option.

LUCKY JIM (Darwin)—Darwin Development Co. has option of purchase and is making examination under superintendency of S. T. Paul. Reported that 25-ton flotation plant and other essential concentration machinery will be installed if development warrants taking over property.

Madera County

ELECTRIC POWER for mines in Grub Gulch district will be provided by extensions made by San Joaquin Power Co. Enterprise and Gambetta mines are preparing for electrical installations. Lack of economic power has been largely responsible for slow development and operation of mines in Madera County since necessity for economic methods of treating low-grade ores is imperative.

Nevada County

GOLDEN CENTER (Grass Valley)—High-grade ore has been disclosed; 10 stamps are dropping on good ore and an increase of capacity of mill is contemplated.

COLUMBIA CONSOLIDATED (Washington)—Mine being placed in shape for production. Mill formerly operated at German mine has been purchased and will be put in commission immediately. Aërial tram from mine to mill is completed and underground work is progressing. Orebodies are large; ore is chiefly free-milling.

DINERO MINING CO. (Washington)—Incorporated with capitalization of $2,000,000 by A. T. Hathaway, W. J. Conners, S. Montague and others. Company will purchase Yuba group of 16 quartz claims at Maybert. Unwatering 960-ft. shaft will begin as soon as repairs are made; shaft will then be deepened to 1,000 ft. and drifting will follow. Mine is equipped with good pumping and hoisting plants and two mills of combined capacity of 30 stamps. Present plans contemplate year of development before milling of ore is undertaken.

Plumas County

GRANITE BASIN district development has brought about reëstablishment of old stage line from Oroville, which had been abandoned for several years. Distance is 50 mi., though Western Pacific Ry. passes within about 10 mi. to west of district. Quincy is nearest important town in Plumas County, situated about 40 mi. northeast.

Sierra County

RATTLESNAKE (Downieville)—Gravel yielding $4 per carload in gold is being worked by Deal & Dills, and breasting will continue during winter.

SPHOON AND LOUISE (Alleghany)—Durston Gold Mining Co. has 20 men grading for buildings, and developing quartz veins on both claims. C. O. Jackson, manager.

MINER'S HOME (Howland Flat)—Under bond to J. Nash. Much gravel worked during summer, with good results. Snowshed built, and work will be continued throughout winter.

ORIENTAL (Alleghany)—Rich ore being extracted at 600-ft. level. Grading for quartz mill under way. Under management of W. B. Pearson, for Croesus Gold Mining Co. of New York.

MOUNT ALTA (Sleighville House)—Gravel paying well. Main tunnel 300 ft. ahead of breasts, and with plentiful supply of water for washing; present crew of 10 will be doubled. Sutro and Chatfield of San Francisco are operating.

WILLOUGHBY (Sierra City)—New payshoot struck, yielding $50 per ton of ore gold in stamp mill, with rich sulphide tailings yet to be treated. An electric plant, air compressor and power drills will be installed later. Owners are Dr. R. L. Jump, of Fruitvale, and E. M. Farrell, of Downieville.

COLORADO

Lake County

DOWN TOWN MINES CO. (Leadville)—Contract let to the Providence Engineering Works for a station pump to be installed on the bottom level when unwatering is complete. This centrifugal pump will have a capacity of 2,000 gal. per min. against a head of 900 ft. and will be direct connected to a 650-hp. General Electric motor running at 1,800 r.p.m. Pumping proceeds with the sinking equipment. No attempt has been or will be made to reopen any of the old workings thus far drained until the unwatering project is finished. Weirs have been provided in the run-off ditch from the Penrose shaft and accurate flow measurements are made regularly.

Summit County

TONOPAH PLACER CO. (Breckenridge)—For quarter ended Aug. 31, net earnings were $114,000.

Teller County

CRIPPLE CREEK PRODUCTION FOR OCTOBER is estimated at 92,000 tons of ore averaging $13.80 per ton. Of this, fully 31,000 tons was waste and dump material averaging $2.60 per ton. The big Golden Cycle mill at Colorado City roasted and cyanided 1,400 tons per day—nearly one ton per minute—a record.

IDAHO

Shoshone County

GOLDEN WINNIE (Murray)—Bennett Bates, who has option on this old gold-tungsten property, is getting out tungsten ore for test run.

HAMBURG-AMERICAN (Little North Fork)—Crosscut at this property has been driven in lode 26 ft. without reaching wall. Assays of 4 to 6% copper are reported.

TERRIBLE EDITH (Little North Fork)—Charles Conn, lessee, received $5,200 from two cars of zinc ore shipped during September. Payment of $80,000 on option falls due Dec. 1.

HYPOTHEEK (Kellogg)—J. O. Tucker, who owns ranch below this mine, has filed suit against company involving water right. Asks damages of $5,000 for diverting water belonging to him and $5,000 for destroying agricultural value of land.

H. E. M. (Wallace)—New 100-ton capacity mill, situated about mile west of Wallace, made its trial run this week with satisfactory results. It is plan of company to connect mine and mill by ½-mi. electric tram, but for present ore will be delivered at mill by wagon.

SUCCESS (Wallace)—At meeting of directors at Wallace Oct. 30, it was stated that orebodies already developed were sufficient to run mill at capacity for about a year. New pump on 1,200 level will be in operation soon, and sinking to 1,400 will commence.

SILVER CABLE (Mullan)—Carload of 30% zinc ore shipped from this property few weeks ago did not yield satisfactory returns. Large body of zinc and some lead has been proven in intermediate tunnel which has recently been connected with lower tunnel by raise of 200 ft. Will continue development during winter with expectation of erecting mill in spring.

SNOWSTORM (Mullan)—No official announcement made but it is understood that Snowstorm has taken over Banner & Bangle mine near Troy, Mont. When Snowstorm was abandoned about year ago, company had $170,000 in treasury and management announced that this would be used to acquire other mining property; understood Troy property has been secured in pursuance of this purpose. Banner & Bangle has been under development for some years by Leo Greenough, manager of Snowstorm. It is silver-lead property.

ROANOKE (Kellogg)—Roanoke company this week gave lease on its property to John Grenfell, of Kellogg, for term of three years; company to receive royalty of 15% on net returns from all ore shipped; lessee agrees to keep at least two men working not less than 30 shifts per man per month. Property is on Elk Creek and is developed by tunnel 400 ft. on vein and shaft 300 ft. deep, from bottom of which vein is explored 100 ft. In both tunnel and shaft there is from 10 to 18 in. of lead ore, high in silver. Hoist is operated by electric power. Mine is 1½ mi. from railroad and is reached by good wagon road.

GEORGIA

FINDLEY RIDGE CO. (Dahlonega)—The Crown Mountain 50-stamp mill has been destroyed by fire. Owners had just completed a ½-mile mule tramway from the openpit mine to this mill and expected to add cyaniding equipment to treat tailings from the amalgamation department. A. H. Head, superintendent.

MICHIGAN

Copper

MICHIGAN (Houghton)—Operations continue at this property with 30 men employed. They are working in a field that has not been operated since the Civil War. Exploration work done to date has given fair indications.

MASS CONSOLIDATED (Rockland)—This property now working to mill capacity and handling highest grade tonnage that ever has been taken from the property, including an unusual amount of "mass and barrel stuff" that goes straight to smelting works.

LAKE (Houghton)—The one thing that is holding back work is the inability to secure drilling machines, the market for which is overtaxed. Calumet & Hecla is just getting the last consignment of one order for 500 machines. Mass expects to have more drills within two weeks, when more rock can be shipped to the mill.

Iron

FLORENCE (Florence)—Orders were given this week by Felix A. Vogel, of New York, to reopen the mine. It has been idle a long time.

BALTIC (Iron River)—About 50 men are employed opening mine. By middle of November about 150 will be at work. Mining will be pushed all winter.

LAKE ANGELINE (Ishpeming)—Cleveland-Cliffs Iron Co., the new owners, started two diamond drills Nov. 6. Some testpitting also being carried on.

FOGARTY (Iron River)—Shovel was started here this week. It is expected that mine will be opened again before long. All of other Pickands-Mather properties on range are operating actively.

CORRIGAN, McKINNEY & CO. (Crystal Falls)—All of ore in stock has been shipped from Kimball, Tobin & Dunn. Only Great Western pile remains. Company has refused to dispose of any more ore at current prices.

MORRIS (Ishpeming)—A motor-size drift was extended 422 ft. during October, breaking the Cleveland-Cliff Iron Co.'s record for rock drifting. Two machines were used and there were four muckers. The rock is hard to drill and break.

HANOUSEK (Wakefield)—Coates & Tweed are preparing to open this property situated short distance from new Wakefield mine of M. A. Hanna Co. Large orebody has been developed. Ore will be taken out with steam shovels. Northwestern road will run spur track from Mikado mine.

PENN IRON CO. (Vulcan)—The Bucyrus company is endeavoring to purchase the patents of the hydro-electric shovel invented by F. Armstrong of Penn company. It is likely that deal will be closed. One of shovels has been doing satisfactory work at Vulcan.

MINNESOTA

Cuyuna Range

HOPKINS (Ironton)—Cuyuna-Sultana Iron Company's shaft is now known as the Hopkins. Production continues at 150 tons daily. Concentrator will operate all winter.

Duluth

MINNESOTA STEEL (Duluth)—Cargo of 1,500 tons of ferromanganese was received this week from Conneaut, Ohio. It was mined in Cuba. Value of cargo was placed at $165,000. More shipments are expected to arrive in near future. Steel making to be started Nov. 10.

MINNESOTA IRON DEVELOPMENT CO. (Duluth)—Company recently organized to take over nearly 9,000 acres of undeveloped fee lands on Cuyuna, Mesabi and Vermilion ranges. E. J. W. Donahue and John Wahl, of Duluth, prominent Cuyuna Range promoters, are directors.

Mesabi Range

RUDDY (Biwabik)—Mine closed down temporarily to permit repairs to shaft.

ORDEAN (Virginia)—Stripping operations begun on this property Oct. 26. Controlled by Oliver Iron Mining Co.

HULL-RUST (Hibbing)—Is the leading 1915 shipper, with daily shipments of 700 carloads.

GREAT NORTHERN ORE—While not authoritatively announced, it is said that the newly organized Midvale Steel and Ordnance Co. has agreement or understanding whereby it controls 300,000,000 tons of iron ore owned by the Great Northern. This gives Midvale about one-third the ore reserve that the Steel Corporation has.

MACE (Nashwauk)—Big steam shovel being used by Butler Bros. in stripping here is attracting considerable attention from mining men. Results are entirely satisfactory. Boom is 90 ft. in length. First dippers used had capacity of 6 cu.yd. They wore out rapidly. Dippers holding 4 cu.yd. are giving better results.

Vermilion Range

SIBLEY (Ely)—Shaft sinking completed and erection of shaft house started. Old Sibley shaft, in which six men were buried about year ago, will be abandoned as soon as new shaft is ready.

MISSOURI—KANSAS—OKLAHOMA

DAY-COOTER MINING CO. (Commerce, Okla.)—Mill will be ready for operation soon. It is east of the Cornfield property.

BEAVER (Commerce, Okla.)—Plant completed on lease north of Commerce; ground thoroughly prospected and reported to be rich.

GARTUNG & CO. (Commerce, Okla.)—Has replaced Ripley tables by Wilfleys. Mill is only tailing mill in district where there are no cleaner jigs, ore being sent from roughers to series of tables.

BLUE GOOSE (Cardin, Okla.)—This new mill of Commerce Mining and Royalty has started producing ore. Beaver mill belonging to same company is rapidly nearing completion and will be running in next couple of weeks.

MURPHY LAND (Galena, Kan.)—Mines leased and operated by James Clifford and George Roland lost machinery and ore by cave-in and flood resulting from broken flume. A new shaft will be sunk in solid ground. The two new pumps installed by James Murphy, owner of the Murphy land, have about drained the ground and miners are returning to work.

EMPIRE MINE (Galena, Kan.)—Large compressor being installed to furnish power for drills, and large derrick is being erected at new shaft sunk recently into ore. A 900-ft. tramway will be built from shaft to mill. Empire is one of largest producers in district, 5½ tons of ore being made per shift; expect to make 10 or 12 per shift as soon as repairs are made and both shafts are in operation.

CHARLES TURNER (Joplin, Mo.)—Expects within next few weeks to commence building of new mill on his lease on Riseling land southwest of Joplin; already has 3,000 tons of dirt ready to hoist and mill. Has three shafts in ore ready to work down to 150-ft. level. Ore was struck at 60-ft. level in paying quantity, but best ore is from 110 ft. to 150 ft. Land was formerly operated by Live Oak Mining Co. of Joplin, Mo., but its mill burned about 7 years ago, and prices of ore did not justify rebuilding at that time, hence ground has been idle since then.

MONTANA

Lewis and Clark County

HELENA MINING BUREAU (Helena)—Members of bureau, incorporated some time ago to try out possibilities of promising mines and prospects in districts tributary to Helena, recently made inspection trip over new property taken over at head of Nelson Creek. Development on four gold claims consists of shaft, drifts and open cuts on surface along outcrop of vein which is 20 ft. wide. Work will be started at once. Mining activity stimulated by work on old Witlatch mine, where leasers have been steadily mining and milling at a profit.

Silver Bow County

BUTTE & BACORN (Butte)—In decree signed Oct. 28 by Judge Lynch, sale of property is ordered to satisfy claims of note holders.

BUTTE & LONDON (Butte)—Work of unwatering shaft completed Oct. 30; sinking begun Nov. 2 and will be kept up at the rate of about 100 ft. per month. Company expects to begin crosscutting early next spring. It is planned to keep three shifts of five men each at work.

BUTTE-ALEX SCOTT (Butte)—Since resuming operations, Oct. 9, 200 tons of ore per day has been shipped, 25% of which was first-class ore. All ore now taken from 2,000-ft. level. As soon as development work on 2,200-ft. level will permit hoisting ore, output will be increased to 400 tons of ore per day. Ore being smelted by East Butte company.

BUTTE & SUPERIOR (Butte)—Company broke all previous records during October, when more than 47,000 tons of ore were mined at Black Rock mine and over 14,000 tons of concentrates produced in mill. From this ore were recovered 15,500,000 lb. of zinc, equivalent to an extraction of 95%. Company's payrolls for month will exceed $180,000, based on $4-per day scale, price of copper having been above 17c. during October. Preparations are going forward for development work at Butte-New York property, which is controlled by Butte & Superior. Crosscut to Colonel Sellers vein has been run on 1,200-ft. level of Black Rock. Vein is from 7 to 8 ft. wide with 1 ft. of 17% zinc in center. Another crosscut will soon be run to Pollock vein.

NEVADA

Esmeralda County

GOLDFIELD CONSOLIDATED (Goldfield)—Production for October was 26,500 tons of ore. Gross yield, $256,000. Net realization, $101,000. September costs were $4.44 per ton and 2,204 ft. of development was done at $4.60 per ft.

Humboldt County

ST. ANTHONY (Toy)—Situated 21 mi., southwest of Lovelock but close to Southern Pacific tracks has practically completed 50-ton tungsten concentrating plant.

Mineral County

PAMLICO PLACER (Hawthorne)—This company has closed down, operations not having been so profitable as samples indicated.

Nye County

TONOPAH ORE PRODUCTION for week ended Oct. 30 amounted to 9,891 tons valued at $203,998 compared with 9,704 tons week previous. Producers were Tonopah Belmont, 2,899 tons; Tonopah Mining, 3,050; Tonopah Extension, 1,850; West End, 881; Jim Butler, 1,100; Halifax, 54; and miscellaneous leasers, 57 tons.

TONOPAH MINING (Tonopah)—For quarter ended Aug. 31, gross value of ore milled was $511,724; net realization of $166,388. Metal losses in milling and refining were $39,699.

CASH BOY (Tonopah)—Bins being erected to facilitate shipping. North drift on 1,450-ft. level shows 3 ft. of ore accompanied by 3 ft. of low-grade material. Air connections will be made with the Victor. Expect to conclude side-line agreement with Tonopah Extension.

HALIFAX-TONOPAH MINING CO. (Tonopah)—Encountered ore at a depth of 1,200 ft. and about midway between the end and side lines of their group of four claims. Drifts on vein being started, winze now down 25 ft. in ore and 54 tons shipped to West End mill are expected to yield between $35 and $50 per ton.

Storey County

ANDES (Virginia)—Cleaning out 175 level and working in old stope above level. Saved 39 cars of ore and fill.

SIERRA NEVADA (Virginia)—At 45 ft. point in west crosscut 2,500 level face in ore averaging $85 per ton. Saved 49 cars of ore averaging $32.34 per ton.

OPHIR (Virginia)—Sinking winze on vein below 2,500 level continued in low grade ore. Central tunnel extracted 355 cars of ore and milled 240 tons. North drift 250 level advanced two sets in milling ore. Jointly with Con. Virginia extended west crosscut on 2,700 level to open vein.

UNION CON. (Virginia)—Six feet of $50-ore exposed at south end of No. 3 stope 2,500 level. In No. 1 raise, best ore shifted to foot wall; ore assaying $21 per ton. Union No. 1 raise north drift face in ore averaging $19 per ton. Saved 142 cars of ore assaying $9.47 per ton and 91 cars averaging $19.73 per ton.

CROWN POINT-BELCHER (Gold Hill)—Water lowered to 70 ft. point below 1,600 level. Recovered No. 1 pump to be overhauled and put in commission 1,400 station. Milling ore saved from 1,300 and 1,400 levels and 779 tons of dump rock and 198 tons of mine rock received at Jacket mill. Bullion shipped.

SOUTH DAKOTA

Lawrence County

HOMESTAKE (Lead)—A crew of men has been put to work taking out tungsten ore from the Harrison claim and a shipment of wolframite is about ready for the market. The material occurs in the flat formation, lying above the quartzite

WASP NO. 2 (Flatiron)—Directors decided to erect a concentrator to handle low-grade tungsten ore. Capacity of plant will be about 25 tons daily. Regular shipments of high-grade tungsten ore are being made. Gold mill is operating on reduced capacity.

UTAH

Beaver County

MOSCOW (Milford)—First car of ore from new zinc strike on 200 level has been shipped.

HORN SILVER (Frisco)—Annual meeting was held Oct. 20, and report will be issued soon after first of coming year. Present directors were reelected.

UTAH LEASING (Newhouse)—Company's new mill, which is to work Cactus dump, is practically completed. Tailings carry about 14 lb. copper per ton.

MAJESTIC (Milford)—Shipments during October amounted to 20 cars of ore from large open cut at Hickory mine. Shaft at Hoosier Boy is being sunk to 600 level, where station will be cut and drifting for vein started. It is planned ultimately to sink shaft to 1,000 level.

Juab County

TINTIC ORE PRODUCTION for week ended Oct. 30 amounted to 132 carloads, estimated at 6,600 tons, valued at $165,000, compared with 121 carloads week previous.

Piute County

MINERAL PRODUCTS (Marysvale)—Initial carload of potash was shipped Oct. 22 by this company, and marks first shipment of potash from Utah fields.

Salt Lake County

UNITED STATES SMELTING (Midvale)—Recent additions having been completed, work was resumed Oct. 20 at concentrator.

UTAH METAL AND TUNNEL (Bingham)—Arrangements are being made to buy the Bingham-New Haven company's property, which adjoins the Utah Metal on the south and west.

ALBION (Alta)—Work was resumed Oct. 23 in neighborhood of caved ground. As soon as timbering is completed, raise can be started on ore. To date three cars of ore have been shipped by leasers.

ALTA RAILWAY TRANSPORTATION CO. (Salt Lake)—Men are at work clearing out right of way between Wasatch and Tanner's Flat, 3 mi. above. It is intended to put in track, 24-in. gage, and to deliver ore from Tanner's Flat to Salt Lake & Alta R.R. terminus at Wasatch for $1 a ton.

UTAH COPPER (Bingham)—The production for September amounted to 14,159,289 lb., as compared with 15,966,543 lb. in August. Company has purchased for $5,000 Ohio Copper ground, including right-of-way. Purchase was made some time ago, but only recorded Nov. 4.

SOUTH HECLA (Alta)—The lease on the Kate Hayes fissure is shipping 40 tons every other day, and 40 tons daily is being sent out by the company from the Wedge workings. The latter ore brings $30 to $40 net smelter returns. On the 250 level the large vein has been followed over 200 ft. and has been crosscut at several points. It varies from 20 ft. in width to 60 ft. at one point.

UTAH IRON AND STEEL (Midvale)—This company filed articles of incorporation Oct. 22; capitalization is $300,000, in shares of $100 each. Purpose of company as stated is to manufacture iron, steel, manganese, coke, copper, etc.; also to build bridges, machinery, and generally to engage in the manufacture of iron and steel structures. C. W. Whitley is president; N. Rosenblat, S. A. Whitney, S. Rosenblat, W. S. McCornick, L. Green, and M. Rosenblat are directors.

Summit County

DALY-JUDGE (Park City)—Development work on 1,100 level has opened full face of silver-lead ore of shipping grade. Most of ore from deeper levels has heretofore been of milling grade.

DALY WEST (Park City)—On account of the water-supply running a little low this fall, the mill has not been operating full time. Development and mining continue, however, and a considerable output of direct shipping ore is being made. Water shortage will be relieved by the first snows.

Weber County

PROMONTORY BAY MINING (Ogden)—Articles of incorporation have been filed by this company to develop zinc and lead property on Promontory Point, 30 mi. west of Ogden. Capitalization is $50,000, par value of stock being 10c. a share. D. J. Sheehan is president. Other companies recently incorporated in the district are: Lake View Mining, Little Valley Mining, Grand View, Indianola, Midlake, and Promontory Zinc.

WISCONSIN

Zinc-Lead District

OPTIMO (Linden)—Company has started construction of a new concentrating mill.

MINERAL POINT ZINC CO. (Mineral Point)—A big deposit of carbonate ore has been proved by churn drilling on the Kennedy land at Highland.

QUINCY (Platteville)—A. L. Utt and others have leased this tract, three miles southwest of Platteville; property is partly prospected by drill and shaft.

BELOIT-ELMO (Platteville)—J. M. Edwards, representing Michigan copper interests, has taken over this property, four miles south of Platteville, and has begun prospecting work.

CANADA

Ontario

TOUGH OAKES (Kirkland Lake)—An initial dividend of $2½7 has been declared.

BEAVER CONSOLIDATED (Cobalt)—This company has purchased group of 10 claims, comprising 360 acres, belonging to Kirkland Lake Gold Mines, Ltd.

SMITH-ARBINE (Sesekinika)—Representative of the United States Smelting, Refining and Mining Co. is sampling this property on which company has secured an option.

ORILLIA MOLYBDENITE CO. (Orillia)—An initial shipment of two tons of molybdenite concentrate has been made to the British War Office. Weekly shipments will be made.

CANADIAN COPPER CO. (Sudbury)—This company has taken over from Smith & Durkee, of Sudbury, the option on a copper location in Connaught Township, east of the West Shining Tree district.

HOLLINGER (Timmins)—For four weeks ended Oct. 7, gross profits were $158,342 from 27,029 tons of ore, average value of $9.66 per ton, the working costs being $3.19 per ton milled. The mill also treated 10,990 tons of ore from the Acme mine.

FOSTER & COFFIN (Sarnia Township)—This American firm has secured extensive leases of oil properties relinquished eight years ago by the Imperial Oil Co. It has cleaned out and shot two wells, now yielding total of 15 bbl. daily, and drilled one new well which started with a flow of 25 bbl. Contracts let for 10 more wells.

SOUTH AMERICA

Chile

BRADEN (Rancagua)—October production amounted to 1,863 tons of copper—a record output except for the extraordinary production of August, 1915.

ASIA

Chosen

ORIENTAL CONS. (Unsan District)—Tonnage milled during September aggregated 25,472 tons. Extraction obtained in Taracol cyanide plant was unusually high, 95.7%. Extraction obtained in the Maibong tube-mill plant was also high, 98.1%, but as extraction for August was low, average extraction for August and September in this plant is approximately 88%. Candlestick mill and cyanide plant ran 13 days 15 hr. during September and were then closed down. Cannot operate Candlestick mine at a profit owing to decrease in contents and width of orebody. Intends to lease mine to Korean tributors. Total bullion output for September as follows: Tabowie mill, $26,935; Taracol mill, $18,914; Maibong mill, $25,783; Candlestick mill, $3,341; Taracol cyanide plant, $50,627; Maibong tube mill, $5,317; Candlestick cyanide plant, $772; total, $131,693.

The Market Report

Metal Markets

NEW YORK—Nov. 10

All of the principal markets were strong and active during the last week, and in each case there was an advance in price.

Copper, Tin, Lead and Zinc

Copper—A rather large business was done during the week, about equally divided between domestic and foreign buyers. It is a noteworthy feature that domestic buyers now appear to be in the market right along instead of buying large quantities all together and then staying away for a long time, which seemed to be their policy a little while ago. On Nov. 6 there was a strike at the Nichols refinery and up to the time of our going to press the plant was still shut down entirely. The deprivation of the large output from this source combined with the well sold position of producers anyhow tended to create some apprehension respecting the supply of near-by copper, and metal for that delivery was readily sold at 18¼c., regular terms. Copper for December and January shipment was sold down to 18c., there being considerable competition among some sellers who were able to contract at relatively low prices for Chile bars and other raw material and sell electrolytic against it at a profit.

In the London market electrolytic copper was offered by American producers from £89 at the opening to £90½ toward the end of the week, but they had to meet the competition of Australian and other producers who took some desirable business at lower prices expressed in sterling, not being troubled either by the high exchange rate or the high freight rate that confront American producers. The freight, insurance and other costs in delivering copper from America to London at the present time amount to 0.75@1c. per pound.

Copper Sheets base price is now 23¼c. per lb. for hot rolled and 24¼c. for cold rolled.

Copper Exports week ended Oct. 23, as reported by Department of Commerce, were 15,229,219 lb.: the chief items being 5,341,186 lb. to France, 4,356,064 lb. to Italy, 3,198,949 lb. to England and 1,680,857 lb. to Russia. Copper imports were 1,652,307 lb. metal and 762,018 lb. in ore and matte; 2,414,325 lb. in all. The larger imports were from Canada, Cuba, Newfoundland and Japan.

Visible Stocks of Copper in Europe on Oct. 31 were: Great Britain, 18,410; France, 1,925; afloat from Chile, 1,050; afloat from Australia, 3,500; total, 24,885 long tons, being 1,068 tons more than Oct. 15, but 4,098 tons less than the Sept. 30 report.

Tin—A good business was done right through the week and the price rose further under the influence of the buying.

Visible Stocks of Tin Oct. 31, including tin afloat, were: London, 5,152; Holland, 315; United States, excluding Pacific ports, 7,687; total, 13,154 long tons, being 2,037 tons less than on Sept. 30, but 2,260 tons mor than on Oct. 31 last year.

Bolivian Exports of Tin concentrates and bars from West Coast ports, seven months ended July 31, were 20,001 tons, equal to 12,355 long tons fine tin. Adding cable reports for August and September mak s the total for the nine months ended Sept. 30 equal to 16,240 tons fine tin. The shipments to New York for the seven months were 499 tons, equal to 318 tons fine tin.

Lead—On Nov. 4 the American Smelting and Refining Co. raised its price to 5c., this following some large and satisfactory selling from that quarter which made it appear likely that the higher price could be obtained. This proved to be the case, a pretty good business on the 5c. basis being done by all of the principal producers. During the morning of Nov. 10 the American Smelting and Refining Co. made a further advance, this time to 5.15c. The St. Louis market held during the week at about 7½ to 10 points under the New York price. Sales of special brands of Missouri lead were made at as much as 10 points premium. The kind of lead that used to be known as "Chemical hard" is especially in demand, owing, no doubt, to the large requirement of it for building sulphuric-acid chambers.

Spelter—A further large business was done, and this week for the first time in many, domestic consumers figured in the market, certain prominent galvanizers being large buyers, both for delivery in this quarter and next. Some export business also was done. The natural consequence of the large buying was to advance the price further. The transactions covered a wide range of prices and deliveries. There was a good deal of business done for November-December shipment, and a good deal for shipment in the first quarter of 1916, while some sales running ahead to next June were made.

Zinc Sheets were advanced on Nov. 4, making the base price $16.50 per 100 lb. f.o.b. La Salle, Ill., less 8% discount. Nov. 9 the price was advanced to $17 per 100 lb., with usual discount.

DAILY PRICES OF METALS IN NEW YORK

Nov	Sterling Exchange	Silver, Cts. per Oz.	Copper: Electrolytic, Cts. per Lb.	Tin: Spot, Cts. per Lb.	Lead: New York, Cts. per Lb.	Lead: St. Louis, Cts. per Lb.	Zinc: St. Louis, Cts. per Lb.
4	4 6388	50	17.70 @17.90	36½	4 90 @5 00	4 80 @4 90	13 50 @15 00
5	4 6475	50	17 70 @17 90	36½	5.00	4.90 @4 92½	13 50 @15 00

10	4 6475	50	17 80 @18.05	36¾	5 15	5 07½	14.25 @15.75

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St. Louis is given as the basing point. St. Louis and New York are normally quoted 0.17c apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars. Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash. The difference between the price delivered and the New York cash equivalent is at present about 0.20c. on domestic business. The price of electrolytic cathodes is 0.05 to 0.10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands. Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St. Louis being the basing market. We quote the New York price at 17c per 100 lb. above the St Louis price.

Silver quotations are in cents per troy ounce of fine silver

Some current freight rates on metals per 100 lb. are: St. Louis-New York 17c.; St. Louis-Chicago, 6.3c.; St. Louis-Pittsburgh, 13.1c.

LONDON

Nov.	Silver	Copper Standard Spot	Copper Standard 3 Mos.	Copper Electrolytic £ per Ton	Copper Electrolytic Cts. per Lb.	Tin Spot	Tin 3 Mos	Lead £ per Ton	Lead Cts. per Lb.	Zinc £ per Ton	Zinc Cts per Lb.
4	24 7/16	74	74½	88½	18.26	163½	162¾	24 5/16	5 02	77	15 89
5	24¾	74	74⅜	89½	18 52	162	161¾	24¾	5 13	77	15.93
6	24 5/16	....	......	.	...	.					
8	24 7/16	73¼	73¾	90	18 62	162	161¾	24⅝	5.10	78½	16 24
9	24 7/16	74⅛	74⅝	90½	18 72	162¾	162¾	24¾	5 12	78½	16.23
10	24⅜	74⅞	75¼	90½	18 73	164¼	164	24¾	5 13	78½	16 24

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0 925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 3 per cent discount. For convenience in comparison of London prices, in pounds sterling per 2240 lb., with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4.80: £15 = 3.21c.; £20 = 4.29c.; £30 = 6.13c.; £40 = 8 57c.; £60 = 12 85c. Variations, £1 = 0 21⅜c.

Other Metals

Aluminum—Market conditions are unchanged. Spot metal is firmly held, 55@58c. being quoted for No. 1 ingots, New York. No quotations on futures.

The reported sale of the property of the Southern Aluminium Co. to the Aluminum Co. of America is confirmed. It is announced that the purchaser will go on and complete the plant, carrying out the original plans with only slight changes.

Antimony—The market is quieter and business has been on a moderate scale, with no material change in prices. Ordinary brands, chiefly Chinese, sold at 36½c. per lb.; while 45c. per lb. is asked for Cookson's.

A United States consular report from Japan says that the large advance in the price of antimony has acted as a great impetus to antimony mining in that country, and the mines at Ichinogawa, Fujinogawa, and Tatsugawa have all been considerably extended; yet their present output aggregates only about 50 tons a month. This quantity is only a fraction of the monthly consumption in Japan.

Nickel.—Quotations for ordinary forms are nominally 45@50c. per lb., according to size and terms of order. A premium of 3c. per lb. is charged for electrolytic nickel.

The International Nickel Co., under date of Nov. 1 announces a base price of 31c. per lb. for Monel metal hot rolled rods. Extras are charged for hexagons and other shapes, for small quantities, etc. Price is f.o.b. works, Bayonne, N. J. Scrap allowance 18c. per lb. delivered to works.

Quicksilver—The market is strong and prices have advanced, the stocks being very light. New York quotation is $100 per flask of 75 lb. for large lots; while $105 up to $110 has been paid for smaller orders. San Francisco reports by telegraph a market strong at $98 per flask, with light stocks. London price is £16 per flask, with same quotation from second hands.

Minor Metals—Current quotations for **Bismuth** are $3 per lb., New York.—**Cadmium** is quoted at 7s. per lb. in London; $1.75@1.90 per lb., New York.—**Chromium** metal, 75c. per lb., New York.—**Cobalt** metal, 97% pure, is sold at $1 per lb.—**Magnesium**, pure, has gone to a high price, $6 per lb. being asked.—**Selenium** varies from $2.50@3 per lb., New York, for large lots; $4.50@5 for retail quantities.—**Tellurium** is quoted at 80s. per lb. in London.

Gold, Silver and Platinum

NEW YORK—Nov. 10

Gold in the United States Nov. 1 as estimated by the Treasury Department: In Treasury against gold certificates outstanding, $1,375,392,789; in Treasury current balances, $216,809,613; in banks and circulation, $605,911,360; total, $2,198,113,762. This is an increase of $56,331,503 during October.

Gold Sales from United States Assay Office in New York in October were $3,452,764, being $432,045 more than in September. For the 10 months ended Oct. 31 the total sales were $55,751,523 in 1914, and $27,892,701 in 1915; a decrease of $27,858,822 this year.

One shipment of gold to Europe is on record this week, $500,000 having been sent to Amsterdam by a New York branch of a Dutch house.

Platinum—The market is quiet, sales being limited by the absence of supplies and the uncertainty of obtaining more. Prices are uncertain and subject generally to negotiation. Quotations are rather nominal at $52@56 per oz. for refined platinum; $56@60 per oz. for hard metal.

Our Russian correspondent writes under date of Oct. 11 that a new sharp advance of the prices is to be noted, due to the great demand for platinum for the internal market. The consumption of platinum has greatly increased, owing to the erection of new sulphuric acid works for war purposes. Many poods have been sold in Petrograd at high prices. The metal is quoted in Petrograd at 46,000@47,000 rubles per pood; at Ekoterinburg, 11@11.25 rubles per zolotnik, for crude metal, 83% platinum. These prices are equivalent to $45.57 and $41.83 per oz. average.

Silver—Our latest advices are to the effect that there has been some substantial buying for the East, and that the low rates of exchange on London have had a hardening effect on the silver market, so that the undertone seems good, with a reasonable probability that the present level may be maintained, subject of course to some fluctuations.

Coined silver in the United States Nov. 1 is estimated by the Treasury Department as follows: Standard dollars, $578,271,655; subsidiary coins, $186,730,386; total, $765,002,041. Of the silver dollars $486,851,787 are held in the Treasury against silver certificates outstanding.

Zinc and Lead Ore Markets

PLATTSVILLE, WIS.—Nov. 6

The base price paid this week for zinc ore was $80@85 per ton for 60% grades. The base price paid for 80% lead ore was $56 per ton.

SHIPMENTS, WEEK ENDED NOV. 6

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	4,717,300	144,200	347,,860
Year	174,033,350	6,028,540	23,072,590

Shipped during week to separating plants, 5,354,000 lb. zinc ore.

JOPLIN, MO.—Nov. 6

Blende, high price $102.50; base per ton 60% zinc, premium ore, $100; medium, $98@99; lower grades down to $85; calamine, base per ton of 40% zinc, $60@70; average selling price, all grades of zinc, $90.28 per ton. Lead, high price $61.10; base per ton 80% metal contents, $54@60; average selling price all grades of lead, $54.82 per ton.

SHIPMENTS WEEK ENDED NOV. 6

	Blende	Calamine	Lead	Values
Totals this week..	12,893,330	724,820	2,127,050	$673,020
Totals this year..	492,174,350	36,708,990	76,723,020	21,851,590

Blende value, the week, $591,840; 45 weeks, $18,980,250.
Calamine value, the week, $22,880; 45 weeks, $859,740.
Lead value, the week, $58,300; 45 weeks, $2,011,600.

No end of excitement was thrust into the market for both zinc and lead. Advances of $10 per ton were the order all along the line in zinc, and lead also was advanced $10 per ton by the Picher Lead Co. which has declined to compete with other buyers at a price over $50 base until this week. The heavy shipment of this week shows the strong buying tendency at the close of last week, and just how heavy this week-end buying will prove cannot be estimated from the various reports current.

Iron Trade Review

NEW YORK—Nov. 10

The year which opened lamely and uncertainly is drawing to its end with a rush. October production and November active furnace capacity are about double the production in January. Export and domestic business are crowding the mills and making postponement of deliveries the rule. Some premiums for early deliveries are reported.

Pig iron is active, with large buying of basic metal, and a rapidly improving demand for foundry iron. The long expected buying movement has set in.

Pig Iron Production again increased in October. The reports of the blast furnaces, as collected and published by the "Iron Age" show that on Nov. 1 there were 276 coke and anthracite furnaces in blast, with a total daily capacity of 101,800 tons, an increase of 4,865 tons over Oct. 1. Making allowances for the charcoal furnaces the total production of pig iron in the United States in October was 3,159,500 long tons; for the 10 months ended Oct. 31 it was 23,668,000 tons. Of this total 17,354,031 tons, or 73.3%, were made by the furnaces owned or operated by steel companies.

Exports and Imports of Iron and Steel—including machinery—in the United States eight months ended Aug. 31 are valued as below by the Department of Commerce:

	1914.	1915.	Changes.
Exports	$140,245,736	$212,697,467	I$72,451,731
Imports	20,745,326	13,451,040	D 7,294,286
Excess, exports...	$119,500,410	$199,246,427	I$79,746,017

The increase in exports has been all in the later months of the year. The August exports were $37,726,822 in 1915, against $10,428,817 last year.

PITTSBURGH—Nov. 9

Movements in the iron and steel market have passed beyond all the bounds indicated by precedent. There are no longer any guesses for the future. The demand for steel is simply overwhelming. There is very little contracting being done for finished steel products, the mills being offered more business, in the form of specific orders, than they can well handle. Conditions may, of course, be easier after the first of the year when many quarterly or half-yearly contracts will have expired, but as no steel seems to be going into stocks it is doubtful whether there will be any noticeable relief. The whole course of the steel market is changing in that specific orders are the rule rather than contracts.

The war demand has broadened. Several very large inquiries have appeared for sheets for war purposes, while the demand for shell steel is heavier than ever, and long term deliveries are asked. The domestic demand has increased sharply, and particularly in railroad quarters. Estimates are made

that as many as 100,000 freight cars may be ordered within the next few weeks.

Last Thursday bars, plates and shapes advanced from 1.50 to 1.60c., through the announcement made by the Carnegie Steel Co. on that day, and it is thought possible the next advance, in the near future, will be to 1.75c., although the market was steady 30 days ago at 1.40c. Sheets are advancing sharply, with many mills practically out of the market. The few first-quarter contracts accepted are at 2.25@2.35c. for black.

Pig Iron—Following the heavy sales of bessemer and basic iron reported a week ago the market has been widely excited. Furnaces advance their asking price sharply and do not care whether or not orders come. Yesterday a sale of 2,000 tons of bessemer pig iron was made for November-December delivery to a domestic consumer at $17.50, Valley, or $1 a ton above the market quotable a few days ago and $1.50 above the market a week ago. Basic iron, which advanced from $15 to $15.50 on the last day of last month, might not be had today at $16. Foundry iron has been rather quiet but will undoubtedly advance sharply on the appearance of any buying movement. The producers are quite indifferent. We quote the market at not under the following: Bessemer, $17.50; basic, $16@16.50; foundry and malleable, $15.50@16; forge, $15@15.50, f.o.b. Valley furnaces, 95c. higher delivered Pittsburgh.

Steel—The market is altogether dislocated by the heavy demand for war billets and for ordinary forging billets, a demand that has caused some sheet mills with attendant open-hearth steel furnaces to close their sheet mills or use purchased bessemer sheet bars in order to make forging billets. A mill that recently sold openhearth sheet bars for first-half delivery is now trying to buy to fill the order, and make high carbon billets. Prices are higher but are not closely quotable, being approximately as follows: Bessemer billets, $25.50@26.50; bessemer sheet bars, $26@27; openhearth billets, $26,50@27.50; openhearth sheet bars, $27@28; forging billets, $42@45, f.o.b. maker's mill, Pittsburgh or Youngstown.

Ferromanganese—Demand has increased for both foreign and domestic on contract, the former being $100 and the latter $110@115, at shipping point. Prompt lots command intermediate prices.

FERRO-ALLOYS

Ferromanganese is still quoted at $100 Baltimore for imported; $110@115 for domestic, early delivery.—**Ferrosilicon** is higher; bessemer 10% is quoted $21.50 at furnace for spot, $21.50 for first quarter and $22 for second quarter. For 15@16%, higher prices, up to $31 at furnace are charged. High grade ferrosilicon, 50%, is quoted $85@87.50 per ton at Pittsburgh.—**Spiegeleisen** is active, with sales at $28@30 per ton at furnace.—**Ferrotitanium** is $8@12.5c. per lb., according to size of order and delivery.—**Ferrovanadium** $2@2.25 per lb. of contained vanadium.

FOREIGN IRON

German steel production in August was 1,157,651 metric tons, being 19,041 tons more than in July. For the eight months ended Aug. 21 the total make was, in metric tons:

	Basic	Acid	Total
Converter	4,248,243	104,202	4,352,445
Open hearth	3,407,799	158,027	3,565,826
Direct castings	283,817	99,104	382,921
Crucible	.....	66,985	66,985
Electric	.....	74,607	74,607
Total	7,939,859	502,925	8,442,784
Total, 1914	11,094,639	469,623	11,564,262

At the close of August there were 221 steel furnaces in operation and reporting production.

The British Blast Furnace report shows that 287 stacks were active in the quarter ended Sept. 30, against 294 in the June quarter and 281 in the September quarter last year.

IRON ORE

Lake Superior iron ore shipments in October were 7,146,875 tons. For the season to Nov. 1 shipments by ports were, in long tons:

Port.	1914	1915	Changes
Escanaba	3,440,992	4,940,081	I. 1,499,089
Marquette	1,651,579	2,836,203	I. 1,184,624
Ashland	3,229,746	4,695,752	I. 1,466,006
Superior	10,320,469	7,348,916	D. 3,571,553
Duluth	6,197,043	14,108,571	I. 7,911,528
Two Harbors	5,511,976	7,886,916	I. 2,374,940
Total	30,951,805	41,816,439	I. 10,864,634

The total sales of iron ore reported for the season, with only a few mines estimated, were 46,667,796 tons. This would leave about 4,850,000 tons to be moved.

Imports and exports of iron ore in the United States eight months ended Aug. 31, long tons:

	1914	1915	Changes
Imports	985,796	797,845	D. 187,951
Exports	518,597	370,965	D. 147,632

The principal imports were 501,588 tons from Cuba, 147,694 tons from Sweden and 32,946 tons from Spain.

Imports of manganese ore for the eight months were 183,029 tons in 1914, and 145,003 in 1915; decrease, 38,026 tons.

OTHER ORES

Molybdenite, 90% MoS_2 is quoted in London at 120s.—$28.80—per unit. The Australian government takes all the ore produced in that country at 105s. per unit.—**Tungsten Ore** remains high, London quotations for wolframite, 65% WO_3, being 55s.—$13.20—per unit. Tungsten ore at New York is quoted at about $38 per unit for ore 60% or over in tungstic acid.

COKE

Coke production in the Connellsville region for the week is reported by the "Courier" at 432,519 short tons; shipments, 441,911 tons. Shipments of Greensburg and upper Connellsville districts, 41,700 tons.

Anthracite shipments in October were 6,505,892 long tons. For the 10 months ended Oct. 31 the shipments were 56,712,087 tons in 1914, and 53,885,003 in 1915; a decrease of 2,827,084 tons, or 5%, this year.

Foreign Fuel Trade of the United States eight months ended Aug 31, as reported by the Department of Commerce, in long tons:

	Exports		Imports	
	1914	1915	1914	1915
Anthracite	2,666,969	2,304,964	15,902	2,300
Bituminous	9,045,260	10,585,583	861,513	951,517
Coke	456,661	513,679	67,003	33,620
Bunker coal	5,038,576	5,027,027	.....	.....
Total	17,207,466	18,434,253	944,418	987,527

The bunker coal, or coal furnished to steamships in foreign trade, is practically all bituminous. The increase this year in bituminous exports was to Italy and to South American countries.

Chemicals

NEW YORK—Nov. 6

The general market has shown some activity and generally a stronger tendency.

Arsenic—Business has been fair, and the market is generally steady. Quotations are $3.75@4 per 100 lb., according to size of order.

Copper Sulphate—Business has been steady, with no material change. Current prices are $6.50 per 100 lb. for carload lots and $6.75 for smaller parcels.

Nitrate of Soda—Demand is improving, though imports have been large. Prices are firmer, quotations being $2.90 per 100 lb. for spot and $2.85 per 100 lb. for futures.

Pyrites—Imports at Baltimore for the week included 5,022 tons pyrites from Huelva, Spain.

Imports and Exports of Chemicals in the United States eight months ended Aug. 31, in pounds:

	Imports		Exports	
	1914	1915	1914	1915
Arsenic	2,861,891	2,422,514	700	8,825
Bleach	27,004,166	6,447,027	12,654	120,126
Acetate of lime	.....	.....	39,946,187	15,040,640
Calcium carbide	.....	.....	23,174,699	26,875,126
Potash salts	24,732,745	13,927,473	450,302	975,840
Sodium cyanide	218,392	3,640,488	...	1,760,387
Soda salts, value	$436,705	$320,952	$8,116	$22,375

Exports include reëxports of foreign material. This statement does not include nitrate of soda nor crude potash salts used chiefly as fertilizers.

PETROLEUM

The monthly statement of "Oil City Derrick" gives the number of new wells completed in October as follows: Pennsylvania grade, 417; Lima-Indiana, 36; Central Ohio, 75; Kentucky, 11; Illinois, 79; Mid-Continent, 576; Texas-Louisiana, 114. The total number of wells completed was 1,308, the total production being 146,291 bbl. There were 249 dry holes and 165 gas wells reported. At the close of the month 2,827 wells were under the drill.

Exports of mineral oils from the United States in September are reported by the Department of Commerce at 213,713,373 gal. For the nine months ended Sept. 30 the total exports were 1,695,583,269 gal. in 1914, and 1,733,628,143 gal. in 1915; an increase of 38,044,874 gal., or 2.2%, this year.

Stock Quotations

The week has been marked by persistent and apparently causeless selling of the "war stocks," accompanied by severe declines. So far it appears simply to be a sharp manipulative attack.

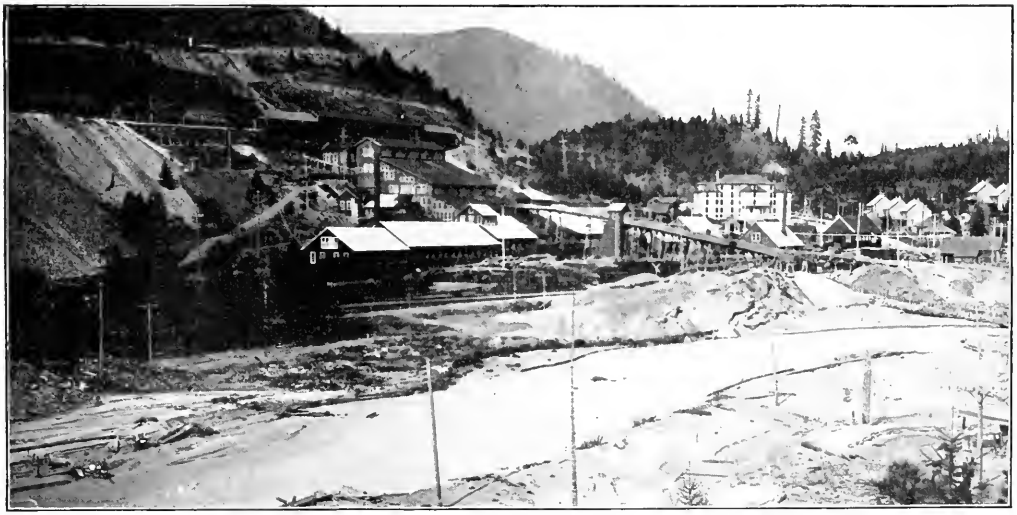
Metallurgy in the Coeur d'Alenes

By Herbert A. Megraw

SYNOPSIS—The ores of the Coeur d'Alene district are varied and complex and have been difficult to treat economically. Their fine structure and the presence of blende and siderite induce serious metallurgical problems. Flotation has been of great assistance in aiding metal recovery from finely ground pulp.

The metallurgical problems of the Cœur d'Alene district of Idaho are varied. The variation is in extent rather than character. Many of the mines produce ores that present only the simple problem of extracting the greatest quantity of commercial metals at the lowest cost, while others, producing ores of highly complex mineralogical character, involve not only the extraction problem, but that of separating the various minerals contained. Upon these problems all the metallurgical plants of the district are working intently and with a degree of success depending largely upon the character of ore to be handled.



THE MORNING MILL, AT MULLAN, WHICH CONTAINS A WIDE VARIETY OF CONCENTRATING MACHINERY

The Metallurgical Problem Not a New One

In considering the metallurgy of the Cœur d'Alenes it may be well to remember that the district is not a new one, but one in which the problems have been attacked over a period of a number of years. Metallurgical skill of a high grade has been employed, and all the successes obtained have been truly earned. With these facts in mind it is clear that any suggestion of improvement ought to be based on careful study of the facts at hand. It would be rash to make superficial observations regarding possible improvements.

The principal part of the Cœur d'Alene district is in Shoshone County, Idaho, in the narrow part of that state, between Washington and Montana. It is near the Montana border and in fact extends close to the state line. There are even one or two properties over the line in Montana. The productive part, however, is principally on the west slope of the Cœur d'Alene Mountains, a rather complex part of the North American Cordillera. The geology, topography and general features of the district are so well known that any review of them here would be entirely superfluous. It is sufficient to say that the structure of the region is complex and that the ores present a great many obstacles to successful metallurgy. This statement ought to be modified to the extent of saying that some of the mines produce ores that are fairly simple and in which one metal will so predominate that all energies are bent toward its recovery. But in other cases the ores are complex and great pains have to be taken, not only to recover the commercially

valuable metals, but to separate them after or during the recovery process.

According to the more careful studies already made, both by the United States Geological Survey and by the companies operating in the district, it has been shown that a large number of metals and minerals exist. Gold and silver have both been found in the native form, but the former is rare in that or any other state, and its recovery has not been found commercially profitable on a large scale. Where found, it is in quartz veins in which some free gold occurs together with auriferous pyrite, chalcopyrite, galena and sphalerite. Native silver was found in the upper levels of some of the mines, particularly in the oxidized ore of the Last Chance mine and in the Hercules. In the lower levels, however, silver is found in combination with lead and with zinc, but its quantity is such that the recovery of the other metals is an essential to the profitable operation of the properties. It is in view of this latter fact that highly developed metallurgy has become an important factor in the life of the district, since it is well known that lead and zinc must be separated if either is to be counted as an asset.

Among the minerals occurring in the Cœur d'Alene ores, galena should be mentioned first, since it is the most important mineral in the district, being a source of the large production of lead and the medium that carries a great part of the silver. It is probable that galena is the most widely distributed mineral in the district, with the possible exception of pyrite. The sulphide of antimony (stibnite) is not rare. It is common in the Wardner district. It forms in small needles or clusters in quartz or, more rarely, in siderite. Chalcocite is found occasionally, but like the antimony, is comparatively rare. Sphalerite, the well-known zinc mineral, is found rather widely distributed, but in quantity not so great as might be expected in view of the great quantity of galena. Sphalerite seems to be more abundant in the mines in Ninemile Cañon and in the neighborhood of Mullan, where it occurs in the Morning mine and considerably complicates the treatment at the mill. Pyrrhotite has been found in Cañon Creek and Ninemile Creek. There is a little of it also in some of the ores from the Morning mine. Both bornite and chalcopyrite occur, although neither of them in large quantities. Pyrite, as has been mentioned, is abundant and widely distributed. All the lead-silver deposits have it, and in the poorer ores it occurs without any valuable metal in combination with it. Pronstite occurs seldom. Tetrahedrite occurs sometimes and has been noted at the Gold Hunter and in small quantities at the Morning mine, near Mullan. It is said to contain antimony but little arsenic, and usually to be in combination with considerable silver.

Influence of Siderite on the Metallurgy

Among the oxides may be mentioned quartz, the most abundant in many of the mines and occurring in all the ore deposits. Magnetite occurs occasionally, as do also limonite and plattnerite, the latter a rare form of lead dioxide. Among the carbonates, calcite is not common, but occurs, as does also dolomite. Siderite, the carbonate of iron, is the most abundant characteristic gangue mineral of the Cœur d'Alene silver-lead deposits. Its presence as a replacement of quartzite constitutes a striking mineralogical feature of the ores. This siderite is one of the most important features of all the Cœur d'Alene ore constituents, and any system of metallurgy must be based upon a thorough cognizance of that fact. It is by no means equally abundant in all the mines, but is prominent in the ores of the Wardner and Mullan group. There are a large number of other minerals that occur in the various ores, all of which tend to complicate the metallurgy of the material. The principal ones have already been mentioned, but the other rarer minerals, which undoubtedly have an influence upon the methods of ore handling, are explained at length in Professional Paper No. 62 of the Geological Survey, to which those who desire further detailed information upon the subject are referred.

Siderite has an important influence upon the handling of the metallurgical problems presented and has been given careful attention and study by the operators of the district. In the paper already referred to, the typical Cœur d'Alene siderite is described as massive, a pale-brown fine-grained aggregate, being not always distinguishable at a casual glance from the quartzite that it has in part replaced. Near the orebodies all gradations exist between nearly pure siderite and a somewhat sericitic quartzite.

The character of the siderite of the Cœur d'Alene district is considered so important in connection with its metallurgical problems that it seems worth while to include the following paragraph by F. C. Calkins in the Geological Survey paper mentioned.

> Siderite occurs in individuals of varying size, but probably the majority of them are larger than the clastic grains of the rock, the mineral being in places crystallographically continuous for a diameter of several millimeters. The form of the individual varies much in regularity. The outlines of many of them, especially of the larger grains, appear ragged, but in such cases the boundaries are seen on close examination to be determined in large part by rhombohedral planes. In other individuals the rhombohedral form of the crystal is more marked, in some being perfect. It is an important fact that in any specimen the crystallographic boundaries can be seen cutting sharply across quartz grains, which proves that the siderite has been developed by molecular replacement of the quartz and not by filling in of cavities. The larger grains in the sandstone and quartzite frequently inclose grains of quartz and, much less commonly, scales of sericite. It is thus evident that the siderite replaces the sericitic fine-grained cementing material more readily than the larger grains of quartz.

A knowledge of the characteristics and formation methods of this mineral will be of great importance in considering the question of ore treatment.

Silver and Lead the Principal Products

In many of the mines there have been large productions of silver and lead from the oxidized galena, which has changed to cerussite. This has practically disappeared, however, at the present time, and the essential lead and silver production is from galena. This mineral occurs in many forms, varying from fine-grained to massive, but is always argentiferous, although the ratio between the lead and silver varies in the different parts of the district. In many of the mines some of the galena occurs so nearly pure that it can be shipped directly without milling, but of course the quantity thus obtained is of no consequence in comparison with the milling production of the district.

The ores are treated in a number of milling plants situated in different parts of the district. The mills now in operation do not include all of those that have

existed in the history of the camp, since some of them have disappeared. The National and the H.E.M. are new. The former is a modern all-slime table and flotation mill, designed and constructed to work the ores of the National mine, but is not yet in operation. The H.E.M. mill has just been completed.

It is a characteristic feature of the Cœur d'Alene district that the mines in different parts produce ores of widely different character. The Bunker Hill & Sullivan mill, at Kellogg, treats a lead-silver ore that is characteristically simple. It consists principally of galena and siderite, there being only minute portions of sphalerite and pyrite. The ore is treated in a series of rock crushers in a separate crushing house and is then delivered over an incline belt conveyor to the mill bins. It is separated by trommels and then concentrated in Harz jigs. Both rolls and Hardinge mills are used for regrinding and Bunker Hill screens for reclassifying.

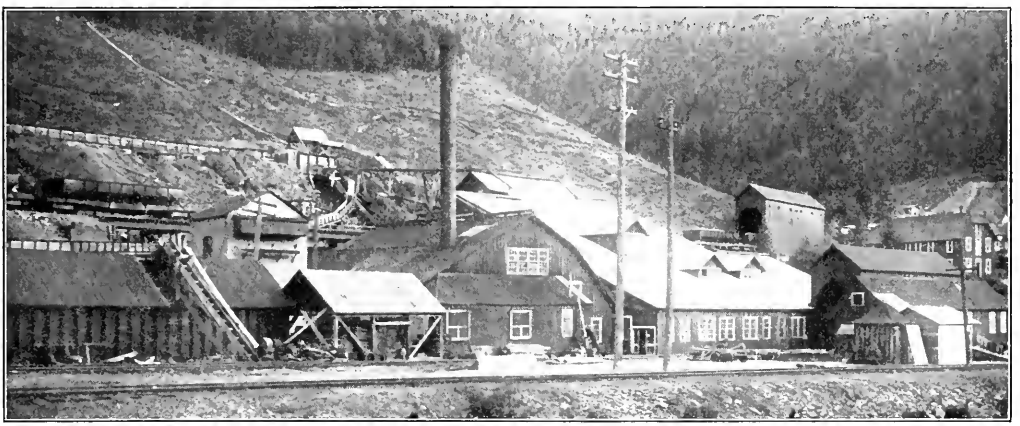
Card tables are used for concentration, and vanners handle the slimes. The slimes tailings are thickened in Dorr thickeners and then sent to the flotation department for further treatment. The whole object of milling treatment at the Bunker Hill is to produce only high-grade material in concentrates. The middlings are all reground and returned until a high-grade product is secured. This extends also to the flotation department, in which cleaning and recleaning are resorted to until a high-grade shipping product is secured.

Complex Ores at the Morning Mill

At the Morning mill, situated just below the town of Mullan, the conditions are noticeably different from those obtaining at the Bunker Hill. The ores are essentially complex, and their treatment is difficult. Galena, the principal ore in all the mines, is here associated with sphalerite, pyrite and pyrrhotite. Siderite, the principal gangue, is accompanied by barite and quartz.

The Morning mill, one of the reduction plants belonging to the Federal Mining and Smelting Co., is one in which all kinds of treatments have been tried in an effort to get the best possible recovery from the ore, and in consequence it contains a widely diverse assortment of machinery. The straight concentration treatment, of course, is patterned after the standard of the district in which rolls, jigs and concentrating tables are used. But there are interesting additional features. There is here one of the few installations of Macquisten tubes. These are designed to make a flotation separation, taking advantage of the tendency of the sulphides to float upon the surface of water when they are gently deposited upon it. The principle is well known, but the plants making use of it are few, there being only two, so far as is known, in the United States. At the Morning mill the process is considered an important step in mill treatment and operates satisfactorily. In addition, a system of froth flotation is also used.

At the Gold Hunter mill, above Mullan, conditions are somewhat similar in that the ore is quite complicated. Besides galena, it contains sphalerite, pyrite, tetrahedrite, stibnite and the gangue materials, siderite, calcite and quartz. The treatment is after the standard system, using rolls, trommels, jigs, tube mills and concentration on Wilfley tables. Flotation is used on the slime tailings, and the flotation concentrates are filtered in an Oliver filter. At the Hunter mill, flotation has been a very considerable aid in the metallurgy of the ore. The Callow flotation machines have improved the mill recovery from 50 to 60%, as obtained by ordinary concentration, to 80%, the concentrates containing only about 6% of silica.



HECLA MILL, NEAR GEM, IDAHO, TREATING ONE OF THE SIMPLER ORES OF THE DISTRICT

The Hercules mill, just below Wallace, has been treating an ore consisting principally of galena. At present the mill is not in operation, there having been some difficulty in making smelting arrangements. It is said that the company has acquired an interest in the Northport, Wash., smelting plant, which is being equipped with lead furnaces and will be used for treating Cœur d'Alene ores. The Hecla mill, near Gem, is another which has an ore of simple construction. The main mineral constituent is galena, and there are only small quantities of sphalerite and pyrite. The ore is treated by the usual combination of jigs and tables, followed, as is now common in the Cœur d'Alene district, by a flotation installation for handling the mineral in the slime tailings. The Hecla mill handles the ores with considerable success and accomplishes a material saving of the contained values.

The Green Hill-Cleveland and the Stewart mills, in Wallace, are both operating after the characteristic system of the district. At the Green Hill mill a large number of experiments in ore treatment have been tried and a large number of flotation tests have been put through. Flotation forms a part of the treatment system here, as in the other mills of the district. Both mills are the property of the Federal Mining and Smelting Co., but the Stewart is under lease to the Stewart Mining Co.

The Frisco mill treats ore that is complicated, since it contains galena, sphalerite, pyrite, chalcopyrite, pyrrhotite and some quartz. It is to be noted that the ores treated at the Frisco mill, as well as those at the Hecla, are noticeably deficient in siderite, a fact that contrasts the treatment with most of the other mills in the district. At the Hecla mill the treatment is simple and easy, but at the Frisco the ore itself is complicated and preparation is not so easy. The general treatment seen at the Frisco mill is that of the standard practice of the districts, which has already been described.

An extremely interesting mill now at work is the Interstate, in Ninemile Cañon, which is treating ores of the Interstate-Callahan Mining Co. This mill is a new one and was prepared for operations just about the time the rise in the price of zinc began. This company took advantage of the situation and, since its product is largely zinc, has made a great deal of money through the operation. The treatment system is the standard crushing, jigging and table concentration system followed in the district, with the addition of a flotation plant for the treatment of the slimes. Other mills working in the same cañon are the Success and the Tamarack.

The National mill, at National, has just been completed and is a modern all-slime table and flotation plant, designed to treat the copper ores of that section of the Cœur d'Alene district. The mill was started and operated successfully, but for some unknown reason has been shut down for some time. Another mill now operating, which has not been described, is the Sweeney mill, at Sweeney, the property of the Federal Mining and Smelting Co. The practice in use there is the same as at the principal mills of the district. The Success, Marsh and Tamarack & Custer are other mills now in operation.

Metallurgical Problems of the District

The principal problem in Cœur d'Alene metallurgy, in common with any metallurgy anywhere, is the separation of the minerals from the gangue. With the simpler ores of the district there has been no great difficulty with this problem, since all that is necessary is a moderate degree of crushing to enable the minerals to be isolated. The separation is accomplished by means of jigs and concentrating tables, usually giving good results. The problem occurring in former times was one principally of handling the slimes produced in the normal course of crushing. The character of the minerals (galena, siderite, etc.) tends perceptibly toward brittleness, and therefore much slimed material was produced in the crushing process. It was formerly handled by slimes tables or vanners when it was handled at all, but the recovery was not all that could be desired. The introduction of flotation has been of great assistance to this step in the metallurgy, making it possible to recover much more of the minerals contained in the slimes.

In the cases where the gangue is principally siderite, the separation of this material from the minerals desired is not so easy. Siderite is an iron mineral itself, and in the rough concentrating processes it is likely to remain largely with the lead and zinc minerals, since its specific gravity is nearly the same as that of blende. In such cases recrushing and stage concentration were necessary. The usual process is to concentrate first, giving a clean mineral, a clean tailing and a mixed middling. The last is then recrushed and reconcentrated, the process being repeated several times until the amount of middling is so small as to be negligible.

After the separation of minerals from gangue, the great problem is in the separation of the lead and zinc. The only way in which this can be accomplished is by repeated step concentrations and regrinding of middlings. Here the flotation process has been of immense assistance, since it enables the successful concentration of minerals ground to an extreme state of fineness—a material that would have been unmanageable under the conditions obtaining a few years ago.

Influence of Microstructure on Metallurgy

Among the complex minerals of the Cœur d'Alene district, there are some in which the ore structure is so complex that successful concentration results are not possible. In many cases the character of the ore is identical with that of ores of extremely high grade, and in many cases the assays show so much value that it might be supposed that a slight degree of concentration would produce concentrates of salable grades. A study of the structure of the ores, however, shows that they are no better than waste. The galena, pyrite, siderite and sometimes chalcopyrite are variable and sometimes extremely complex. The problem hinges entirely on the microstructure of the ores, since there are fine inclusions of ore minerals in gangue. Under the microscope the essential and characteristic feature is the distribution of multitudes of microscopic specks and threads of galena and siderite as inclusions in a mass of nonmetallic gangue. The galena is held in microscopic threads and specks as inclusions in the siderite gangue. This fine dissemination compels extremely fine crushing and complicates the metallurgy. In many cases the intermingling of the minerals is so finely grained as to be microscopic, making it altogether impossible to crush fine enough to allow a separation of the two minerals. It is possible, however, to improve the extraction with the finest of grinding, and it is upon this point that flotation has come to the aid of metallurgists and allowed successful handling of these materials ground to an extreme state of subdivision.

Japanese Sulphur Industry

The export of sulphur from Japan has for years been on the decline, some of the small mines having been compelled to stop working. But since the war broke out, the demand in the foreign market has improved and quotations have gradually risen. The export this year up to the end of August, according to the *Japan Advertiser,* was 27,948,607 lb., valued at $203,048, showing an increase of 4,638,451 lb., compared with the figures for the corresponding period of last year. The destinations have in the past been the United States and Australia in the

main, with Canada and India coming next, only an insignificant amount being shipped to Europe. Since the war, however, the European supply to Oriental countries has been stopped and the demand in Europe itself has increased.

Mineral Output of New York

The mineral production of New York in 1914 is given as follows in a report on the mining and quarry industry of the state, by David H. Newland, assistant state geologist: Cement, portland and natural, 5,899,804 bbl.; salt, 10,389,072 bbl.; natural gas, 8,744,681,000 cu.ft.; iron ore, 751,716 long tons; gypsum, 513,094 short tons; petroleum, 933,511 bbl.; mineral waters, 8,480,669 gal.; talc, 74,075 short tons; pyrite, 61,513 long tons; graphite, 2,483,339 lb.; garnet, 4,026 short tons; feldspar and quartz, 2,375; metallic paint, 7,321; crude clay, 7,109; emery, 763 short tons. Other mineral substances, including limestone, sand and gravel, sandstone, granite, marble, apatite, diatomaceous earth, etc., to the value of $8,164,810 were also produced.

The production of iron ore showed a marked decline from that of the preceding year, which was 1,217,899 long tons. Other changes were not large, except in the case of salt, which declined about 430,000 tons, and talc, which increased about 11,000 tons.

Advance in Chemical Prices Due to the War

The Boston *Transcript* has compiled a table showing the advance in chemical and drug prices caused by the war. From this table some of the chief inorganic items are reprinted here.

CHEMICAL PRICES

Material	June 1, 1915	Nov. 5, 1915
Acetate of lime, cwt.	$2.50	$14.50 @ $14.55
Acetic acid, U. S. P., lb.	$0.04½ @ .05	.07½ @ .08
Alum, potash, cwt.	3.50 @ 4.00	6.25 @ 7.00
Arsenic, red, lb.	.07¾	.19 @ .20
Bichromate of potash, lb.	.16	.24 @ .25
Bichromate of soda, lb.	.06	.17 @ .18
Bromine, lb.	.82	5.00 @ 5.50
Chrome alum, lb.	.08	.21 @ .23
Lead acetate, lb.	.10½	.13 @ .13½
Magnesium chloride, ton	$32.00 @ 36.00	75.00 @ 80.00
Muriate of potash, ton	155.00	300.00
Permanganate of potash, lb.	.65	1.25 @ 1.50
Prussiate of potash, red, lb.	.70	4.25 @ 4.75
Prussiate of potash, yellow, lb.	.53	.80 @ .85
Zinc dust, lb.	.16 @ .16½	.35 @ .40

Mining in India in 1914

The Chief Inspector of Mines in India has just issued his annual report for 1914. In addition to information regarding persons employed, accidents, health and sanitation, the following figures of output are given: Mica, 38,189 cwt.; manganese, 555,672 long tons; gems, 304,042 carats; gold, 19,813 oz.; copper, 4,400 long tons; wolfram, 31,526 cwt.; bauxite, 9,280 cwt. Iron, slate, fuller's earth, salt, chromite, magnesite and other minerals were produced, but the quantity is not stated.

It should be noted that this report does not give a complete review of mining in India, but confines itself to those mines and quarries coming under the scope of the Indian Mines Act of 1901, which excludes quarries under 20 ft. deep. The complete figures are given in the records of the Indian Geological Survey.

Mining Methods at Braden*

"El Mineral Teniente" property of the Braden Copper Co. at Rancagua, Chile, is situated on the rugged slopes of a part of the main Andean Range in latitude 34° south and longitude 71° 20′ west, at an altitude of about 8,000 ft. The mine is a very old one, dating its history, as stated by William Braden†, back to the Eighteenth century. The mine operations up to 1906 were on a very small scale and consisted of a gopher system of mining rich veins, concentrating by hand sorting, and transporting about 15 mi. by mule-back for direct smelting. At that period the operations of the American company commenced in earnest, and from that time on the mine has gradually been enlarged, until it has attained its present 3,000- to 3,500-ton daily output.

The deposit consists of a series of irregular lenses formed about the periphery of an old volcanic plug slightly tilted to one side. On one edge the surface has been eroded and has lost its mineral completely; for active mining operations about four-fifths of the circumference of the crater is left. The volcano itself would rank as a fairly large one, having a diameter of about ¾ mi. and a roughly circular outline about 2½ mi. long. The country about the mine consists of andesite flows through which the tuff plug now occupying the crater was forced.

Brecciation Favorable to Ore Deposition

The materials close to the volcanic center were so thoroughly shattered that they formed a brecciated deposit, making a most favorable point of deposition; and it is in the brecciated portions of the lenticular orebodies that the richest ore is found. The mineral sulphides, however, formed ore in the andesite at some distance from the crater. Generally speaking, the materials with which the mine is interested are the tuff composing the volcanic plug, the breccia, and the andesite composing the country rock. As a rule, the tuff is not mineralized except close to the breccia contact or at such points as fumarolic vents have been formed. The actual contact between the tuff and breccia is not always distinct, but the former includes rounded fragments of porphyry and the latter, angular fragments of andesite, which makes the difference easy to detect.

The contact between breccia and andesite is easy to note as a rule, but on the Teniente side the gradation from shattered andesite to andesite breccia is a most perplexing one. The breccia does not always appear as an intermediate material between the tuff and the andesite, but on the tuff-andesite contact the ore is not so rich nor the width so great. At various places in the mine old fumaroles are encountered in which oxidation has taken place at depth, and at times small chambers containing heads of wire copper coated with oxide are found in company with the usual black sulphides and oxides and yellowish iron stains of limonite.

The limit of ore on the crater side is generally the tuff, although sometimes false contacts—thin tongues inserted into the breccia—occur, on the inside of which there is good ore-bearing breccia. On the country-rock side the limit of ore has to be determined by assay, but is also detectable by the lessening of the fractures and the blockier appearance of the andesite.

*Excerpts from article by H. R. Graham in "Teniente Topics," Sewell, Rancagua, Chile.

†"Eng. and Min. Journ.," Sept. 4, 1915.

The copper ore occurs in both breccia and andesite, essentially as primary sulphides in the form principally of chalcopyrite, as bornite, as secondary chalcocite, a black sulphide between tetrahedrite and enargite and some of the carbonates, silicates, sulphates and oxides of copper. Zinc blende, iron pyrites, magnetite, galena and occasionally native copper are also found.

The topography of the region is steep and rugged, devoid of vegetation, frequently visited by strong winds, heavy snows and snow-slides. This topography aids mining, drainage and ventilation by allowing the mine to be opened by adits, but makes difficult its operation by the lack of safe room for buildings and storage of supplies and by the difficulty of access.

On the upper levels of the mine live between 500 and 800 people, who are housed either in large rooms cut in the rock or else in wood and *calamina* houses perched on the hillsides.

The Mine Development

The mine consists of three principal orebodies—the Fortuna, the Regimiento and the Teniente—with a total reserve of about 90,000,000 tons, developed and probable, with good prospects for largely increasing this tonnage by future development. The two smaller orebodies, of secondary importance but included in this tonnage, are the Centinela and the Bornite. The Teniente orebody is now being developed to an operating stage. The full extent of ore in this section has not as yet been determined.

The Fortuna orebody, from which all the ore at present is being won, is operated by the principal levels, where, with the exception of three, shrinkage stoping operations have been nearly completed and caving is now in progress.

Development consists of driving adits along the contact of the tuff and breccia or andesite. Once the ore is reached, crosscuts are put in about every 34 m., and in this way, blocking out every 100 ft., the plan area of the ore at that level is determined. The extent of ore was first determined in the Fortuna on the No. 2 level, then blocked out on the No. 3 level in the same manner, and the ore between them proved up by inclined raises running from the tuff to the limit of commercial ore and back, to ultimately connect to the level above. The tuff is on the hanging wall.

After a block of ore is outlined the crosscuts used in developing the body are utilized as starting points for the actual mining operations. In these crosscuts small raises, at from 7- to 8-m. centers, are driven up into the ore at 45 deg. until the face of the raise reaches the far side of the stope. In some cases this is 10 m. on the incline in the old system; in the present Teniente system it will be about 5 m. When this drive is completed, a timber chute with an arc gate is erected. A machine of the standard stoper type is put to work, and these various raises are connected, one to the other, by a belling-out process, which ultimately leaves a series of circular holes. These at last extend across the orebody.

In the meantime, in the pillar left between each two of these sets of openings an inclined raise has been driven, and at a point about 12 m. vertically above the level a horizontal working known as *cruzado* is driven from the raise to a stope formed by the joining of all the chute holes. The width of this stope, depending on the kind of rock, is generally 22 ft., and the length, dependent on the width of the orebody, varies from 60 to 350 ft.

Once the *cruzado* is connected, the chutes are allowed to fill up with broken ore, after which all communication between stope and level is by these *cruzados*. The stope is filled with broken ore to within 6 to 8 ft. of the back and then trimmed into shape by means of carefully placed holes put in by the hammer drills. Pipe lines are run up the inclined manway raises to supply air for the operation of the drills and to the rooms for ventilation. Once the stope is "lined up," machine drillers start work in the ratio of about one drill to every 40 ft. of stope length. An average drill shift consists of fifteen 5-ft. holes per machine, which should break, with 1½ sticks of ordinary 34% gelignite per hole, about 60 tons of average stope rock. On the principle that each cubic meter of rock in place occupies $1\frac{3}{4}$ cubic meters when broken, it is possible then to draw out 24 tons for each 60 tons broken and leave the same distance of 6 to 8 ft. between the unbroken back and the broken ore pile.

Stoping and Caving

No holes are drilled in the center of the stope, but each drill from the extreme wall drills one vertical hole and one slightly inclined hole toward the center of the stope. Then at a 5-ft. distance, the miner drills two more similar holes and continues thus until his shift is over. By alternating this process from one side day shift and the other side night shift, a great deal of rock in the center of the stope is robbed of its side supports and has to fall by itself, which tends to cheapness. All stope work is done on contract price per foot of hole. Additional men are employed to deliver steel to the stopes; mechanics repair machines and keep air lines in shape; and on the level below, trammers continually draw off the excess break to leave the working space necessary between the back and the ore pile.

This stoping operation goes on until the back reaches a point 30 ft. below the level above, at which point a final blast to fill the stope is fired and the work discontinued. The raises in the pillars are continued to connect to the level above for ventilation, and as one pillar raise is run in the hanging-wall end and in the next pillar in the foot-wall end, each stope always has at least two entrances and a continuous natural ventilating draft. The drillers load and shoot their own rounds; each shift at 15 min. before quitting time has all its holes ready to spit. When the raising is finished, the stopes are left filled until caving operations above have been completed.

The best arrangement of stopes as developed here, to suit the ground, is to have a 7-m. stope and a 5-m. pillar, which, in the case of bad ground, can be changed by narrowing up the stope and increasing the pillar without having to change in any way the level workings. Chutes are best spaced about 7-m. centers, and it has been found by experience that 50-m. differences in elevation between levels make stopes most easily worked. Each stope has its crosscuts immediately under it and running parallel to it, that is, across the width of the orebody.

In the beginning of operations no timber except chute sets and a slight amount of material for crossings and station sets is needed, but when stoping operations cease and caving begins, more timber is necessary to hold open the haulage drifts. As the whole success of caving depends on the superincumbent pressure that can be brought to bear on the unbroken pillars, it is necessary to secure weight as quickly and as evenly as possible, and that means heavy ground on the haulage ways. These ways then have to be timbered, relieved, caught up, angle-braced and kept in repair.

The process of caving consists of cutting off the pillar at the foot wall and hanging wall by means of small stopes, or by running raises in which large blasts are fired, either electrically or with fuse, and then by running a pillar drift along the bottom of the pillar immediately above the level and blasting a series of pits here, the pillar is completely cut off and has to fall. If by any chance it tends to arch, this arch is broken by a heavy blast. The material resulting from the chute blasting is pulled out and the pillar caves down.

The most important consideration is the securing of even weight and then an even pulling so that the extraction is not spoiled by waste admixture. Definite data are kept on each chute; its expectancy above the level is figured and its extraction calculated when waste definitely appears. Careful chute sampling is done on the caving level, and chutes running below commercial grade are abandoned unless it is known that the chute has ore above it. In case there is known ore above and the waste is merely a little fine material that has sifted through, the chute is run, the material sent to waste and samples taken until it runs ore again.

Nevada Consolidated Report

Nevada Consolidated Copper Co. reports for the third quarter of 1915 a production of 18,516,121 lb. of copper, divided as follows: July, 6,292,413 lb.; August, 6,201,858 lb.; September, 6,021,850 lb. During the quarter 837,374 dry tons of Nevada Consolidated ore, averaging 1.66% copper, was milled, a decrease of 11,781 tons from the previous quarter. Of the tonnage milled, 98% was supplied from the pits and 2% from the underground workings of the Ruth mine. In addition, 29,681 dry tons of Giroux Consolidated ore was milled. The cost of copper produced, including Steptoe depreciation and all charges except ore extinguishment and after crediting all miscellaneous earnings, was 8.01c. per lb., as compared with 8.93c. for the previous quarter. The earnings for the quarter are computed on the basis of 15.876c. per lb., and all unsold copper on hand and in transit is carried in inventory at 13½c. per lb. Gross earnings for the quarter were $1,590,621. Depreciation of plant and equipment was $143,879; ore extinguishment, $84,593; and $749,796 in dividends were paid, leaving a net credit to earned surplus of $612,352. At the pits 866,713 cu.yd. of overburden was stripped during the quarter. Work was also actively continued in preparing the Ruth mine for underground operations, with the result that at the end of the quarter the hoist and underground trolley were running smoothly, the living quarters were about finished, and it was expected that all of the surface work with the exception of the installation of a larger air compressor, already ordered, would be complete by the end of October.

Earth Tremors on the Rand

By A. Cooper Key*

Johannesburg has been experiencing earth tremors lately. No serious damage has been done to buildings, but in some cases cracks have developed and the question of insurance against damage is being discussed. The subject of causation and prevention of tremors is being investigated by a committee consisting of R. N. Kotze, government mining engineer; R. A. T. Innes, Union astronomer; and David Wilkinson, consulting engineer of S. Neumann & Co., mining financiers.

In the year ended June, 1911, there were 19 tremors; to June, 1912, 36; to June, 1913, 113; to June, 1914, 186; and to May, 1915, 466. The shock zone has a radius of about 3 mi. from the center of the town of Johannesburg.

H. E. Wood, chief assistant at the Union Observatory, Johannesburg, believes the shocks were due to mining operations, but does not think there is any danger to life and property on the surface by the tremors. Earthquakes, said Mr. Wood, always went over fairly large areas and involved the shifting of hundreds of millions of tons. In the case of the Rand, the amount of energy distributed could not be very large and local tremors were probably occasioned by relief of local strains only. A self-recording seismograph in use at the observatory enabled the separating, with no difficulty, of records of local tremors from those of more distant origin.

The record tended to show a rapid increase in the annual frequency of the tremors, but the numbers were affected by increased sensitiveness of the machine. The frequency and intensity of the tremors should increase from year to year, but there was no definite sign of any annual, weekly or diurnal period. The source of the disturbances was in the near vicinity of the Witwatersrand and confined to a small region at a comparatively shallow depth. If the source of disturbance were very deep, say several miles, the tremors would be felt simultaneously over a much larger area. But records of simultaneous shocks along reef towns are rare.

This led to the inevitable conclusion that the local tremors must be considered the result of mining operations. He did not think water pumping was a serious contributory cause, nor that air blasts or pressure bursts were directly connected with a local tremor. He considered the local tremors were the result of the natural tendencies of large subterranean cavities to close up under the influence of gravitation. This tendency is more marked as the horizontal dimensions of the cavities are greater than their vertical dimensions, which is the case on the Rand. The greater part of Johannesburg is built on strata below the reef, and the region will be subject to vibration effect, but not to any actual bodily displacement or subsidence. The possible danger has been recognized and methods of mining have been adopted to combat it.

Mr. Kotze, government mining engineer and chairman of the commission, said that in some instances where there had been underground subsidence, the surface of the mine had dropped 14 in., yet no shock had been recorded. On the other hand, it seemed that shocks had been simultaneously recorded with mine-working subsidences.

---

*P. O. Box 3621, Johannesburg, South Africa.

E. J. Moynihan, an official of the Union Mines Department, declared that the primary cause was that the mining companies had made a tunnel in the earth some 30 mi. long and a few feet high. They had been widening this for 20 years until, on the average, it was something like a mile wide. The tunnel was also inclined in the direction of its width. Well, the roof was falling in. That was all. Then there were secondary causes. There was the contraction of the wedge overlying the tunnel due to its falling temperature, as the air circulating through the tunnel had cut off the upper wedge from direct conduction of heat from the mass of the earth below. Temperature in the upper wedge had consequently been greatly changed and much lowered in course of time. The wedge as a whole contracted and its center of gravity moved downward, which accounted for the shearing of formation above the drive pillars on the southernmost of the reefs worked. It also tended to make the strata part on the lines of strike faults, thus allowing fault blocks to slip vertically. Pumping operations tended to produce effects similar to those caused by contraction. A possibility to be borne in mind was that the thrust against the granite boss, which had tilted and faulted the Rand beds, was not a "dead" thrust, but still "living" and in operation.

Sand filling or something better would have to be adopted systematically and generally. Even so, the increase in the severity of the tremors was likely to continue for many years. He suggested filling stopes with coarse rock, then filling with stuff the size of macadam and finally flushing in as much sand as possible into the remaining interstices. The total compression in such a mass would be very much less than in the mere mass of sand flushed down with water. He believed that, with a proper amount of compression, sand filling would stop the tremors in five or ten years.

J. H. Twiddy, deputy inspector of mines, attributed the tremors to mining operations. He thought the tremors were caused by slips along faults.

A. C. Sutherland, mining surveyor in the Mines Department, thought a connection had been clearly established in some instances between the shocks and underground happenings. He believed they could be lessened by the removal of the small pillars. The pillars to be left should be very big. Sand filling would lessen the tremors, as it would pick up a certain amount of weight, but it would not do away with the shocks altogether.

Business of Henry R. Merton & Co. Supervised by British

An inquiry to the president of the Board of Trade in London, regarding the supervision that was being exercised over Henry R. Merton & Co. and other companies in which alien enemies were interested, elicited the response, according to the *Financial Times* of Oct. 29, 1915, that an inspector of Henry R. Merton & Co. had been appointed on Oct. 3, 1914, and that subsequently a supervision of the business had been appointed under the provisions of Section 12 of the Trading With the Enemy Amendment Act of 1914.

Speaking generally, the president of the Board of Trade is quoted as saying that "it was not proposed that all companies controlled by alien enemies be stopped from continuing to do business, as some of these companies serve a useful purpose. The businesses are conducted under restrictions imposed by the Trading with the Enemy acts and I doubt whether it would be expedient in the public interests to prevent their being carried on."

Metal-Mine Accidents, 1914

According to figures compiled by Albert H. Fay, mining engineer, Bureau of Mines, the number of fatalities in the metal mines of the United States during 1914 was 559, as compared with 683 in 1913. The number of men employed, however, for 1914 was 158,115 as compared with 191,276 in 1913. There is a slight reduction in the fatality rate over the previous year, the rate being 3.54 per 1,000 employed in 1914, as against 3.57 in 1913. There were 5,073 serious injuries, which resulted in a loss of time of 20 days or more, as compared with 5,890 for the preceding year. The serious-injury rate for 1914 is 32.08 per 1,000, as compared with 30.79 for 1913. There were reported 25,143 slight injuries, which resulted in a loss of time of less than 20 days, as compared with 27,081 for the previous year, or 159.02 per 1,000, as compared with 141.58 for the preceding year.

The higher injury ratios, however, for 1914 are not necessarily due to the increased hazard of mining. The enactment of workman's compensation laws and the educational campaign that has been carried on for the last three or four years by the state inspectors, mine operators and the Bureau of Mines have resulted in the mining companies keeping better records than formerly. The figures reported for 1914 are therefore more nearly in accordance with the hazard of the industry than were those for previous years. The number of companies reporting accidents in 1914 was 4,805, of which number 585 represented copper mines; 3,536, gold and miscellaneous metal mines; 196, iron mines; 248, lead and zinc mines in the Mississippi Valley; and 240, miscellaneous mineral mines.

The metal-mine-accident report for 1914 contains also a study of mine accidents by mining methods, which is a departure from the previous reports and brings out some valuable information concerning stoping, caving and room-and-pillar systems of mining as related to mine accidents. This part of the report deals with 258 mining companies representing 75,453 employees actually engaged in underground or openpit mining, exclusive of those employed at surface shops and yards. The fatality rate for the various mining methods, classified, is as follows:

Overhand stoping in narrow orebodies	4.90 per 1,000
Overhand stoping in wide orebodies	5.23 per 1,000
Room and pillar	5.76 per 1,000
Caving systems	5.10 per 1,000
Openpit with steam shovel	2.50 per 1,000
Openpit without steam shovel	2.28 per 1,000

The average fatality rate for this group of mines, based on underground and openpit employees, is 4.78 per 1,000 men employed. The serious-injury rate for the same group of mines is 51.67 per 1,000, while the slight injuries show 270.46 per 1,000.

The states of Kansas, Minnesota, New Jersey, New Mexico, Oregon, South Dakota and Virginia, and the territory of Alaska show a reduction of more than 20% in the fatality rate as compared with the preceding year. Nevada and Montana are the only states that show a continuous reduction of fatal accidents during the four years covered by the bureau's reports.

Motor Travel in Desert Country

By Lewis H. Eddy*

SYNOPSIS—Record of 500 miles of automobile travel over mining districts in southern California desert country. An average of $25 per day, or 40c. per mi., for use of automobile and service of driver, carrying two or three passengers, is the usual rate. Even this high cost is more economical than horse stage or team transportation if saving of time and the opportunity to travel at will are important. Motor vehicles are coming to be the logical successors to horse stages and freight teams in desert transportation and in the development of opportunities for railroad advancement.

The automobile is crowding the burro off the desert and rapidly reducing the number of horse-stage stations. The motor truck is gradually displacing the freight wagon and lowering the cost of haulage. The railroad is advancing into the regions explored by the automobile and broadening the trail of the prospector. During three weeks of travel by rail and automobile we saw only six burros in action—five at Randsburg ready for the trail, and one under the saddle in Panamint Valley. We saw only two horse stages—one between Ballarat and Skidoo, the other between Ogilby and the American Girl and Tumco mines. But we saw probably 50 automobiles carrying passengers or loaded with parcel post, express and mail, and motor trucks hauling ore and supplies. Deserted stage stations were numerous—concrete railway stations increasing. The automobile and motor truck are on the desert to stay, and the manufacturer that studies desert transportation will find a large field for exploitation and opportunity for improvement in design and construction.

THREE METHODS OF TRANSPORTATION IN THE WESTERN DESERT COUNTRY
First the "desert rat" with his burro; then the classic stage coach, and now the automobile

Crossing the Desert to Reach the Hills

Desert travel and the geological and topographical situation of the mines and their relation to the desert regions in southern California are not generally understood. Metal mining on the flat floor of the desert is not common practice. Some of the mines are situated in low isolated hills immediately surrounded by broad plains more or less arid, but usually they are in the foothills that form the rim of the desert, or in the higher ranges that separate the regions. The gold placers are in the gulches and low hills. Saline deposits are in the lower flat regions or in natural depressions. However, it is necessary to cross desert country to reach most of the mines in the Mojave, Death Valley and Yuma regions, and the most economical mode of travel is by automobile to points where the railroads have not been extended. If you own your automobile you may, with assured economy, start from any point south of Tehachapi and cover the entire desert regions of southern California and southwestern Arizona without going a mile by rail. If you are dependent on hired automobiles and unacquainted with the country and the roads, you had better make some use of the railroads. In either case it is not wise to travel alone. My visit to mining districts in these regions was in company with H. M. Wolflin, mining engineer, of San Francisco, whose duty was the inspection of mines under the workmen's compensation law.

We started from Los Angeles, traveling by rail via San Bernardino to Kramer, a station on the main line of the Santa Fe, where we transferred to the Randsburg branch. This runs north through the main body of Mojave Desert and has its terminus at Johannesburg, 35 mi. north of Kramer. Johannesburg is situated at the eastern edge of Kern County in a small basin between Rand Mountains on the west and Red Mountain on the east. Randsburg is a mile and a half west, situated in a similar basin in the Rand Mountains. Both towns are geographically and topographically of the desert. But the midsummer visitor imagines he is on the desert, and imagination goes a long way toward establishing belief.

Mining Camp on the Edge of the Desert

Atolia, the tungsten camp, 5 mi. southeast of Johannesburg, on the western edge of San Bernardino County, is geographically within the Mojave Desert, though the elevation is only 300 ft. lower than at Johannesburg and Randsburg. The contour line of the United States Geological Survey places Atolia at 3,250 ft., and the bench marks give the elevation of Johannesburg at 3,536 and Randsburg at 3,523 ft. above sea level. Considering the altitude, you would say this is not much of a desert. It is a desert only by distant relation and by lack of greater development of water resources. Wait till you get to Panamint Valley and on the edge of Death Valley or down Yuma way. You will then recall Atolia as merely a warm spot on the railroad and Johannesburg and Randsburg as oases. We suffered as much discom-

*Associate editor, San Francisco, Calif.

fort from the heat of the sun in the garden regions of Sacramento and San Joaquin valleys as in the Randsburg region.

Some people imagine that Skidoo is a desert mining camp and a pretty close relation to Death Valley. It is 15 miles west of the center line of the valley and about 6,000 ft. higher. You must cross either Panamint Valley or Death Valley to reach Skidoo, but after you are there you forget all about deserts.

These statements should not be construed to mean that desert travel in the regions we traversed is an enjoyable outing. On the contrary, it is a man's job to cross Mojave Desert and Panamint Valley in any month between April and October, and the wise man keeps away from Death Valley during that period unless his wisdom is of the desert. During the two weeks spent in these regions we made headquarters at Johannesburg, visiting the mines in the Randsburg, Stringer and Atolia districts afoot and by automobile, and made two visits to Searles Lake and one to the Skidoo district. After completing work here, we traveled by automobile from Randsburg to Mojave, stopping on the way at Kaehn Springs and Cisco; thence by rail to Yuma and from that point by automobile to the American Girl and Tumco mines in Imperial Valley. In Randsburg region and the Searles Lake and Skidoo districts and to Mojave, we traveled in an Overland machine driven by Ed Neihaus, of Randsburg.

Cross-Country Motor Travel not Cheap

The usual charge for automobile service in the mining districts of southern California and southwestern Arizona is $25 a day for two or three passengers. This charge varies according to roads, distances, and other conditions that may not always be foreseen. A short day and an easy road may reduce the cost, and a long hard day over bad roads may increase it. For the first trip to Trona and return to Johannesburg we paid $25. The direct distance to Trona and return is 80 mi. The trip included an early morning visit to Atolia and a 10-mile drive over Searles Lake. Including the time spent at supper at Garden station the trip occupied 14 hr. For the journey to Skidoo and return to Johannesburg, including two nights and one day at the mines, we paid $100. We occupied one day each way on the road, including a short run off the road to the Cashier mine at Harrisburg and two stops at Trona and time consumed with motor and tire troubles. The total distance traveled was 220 mi.

One hundred dollars for two days' actual use of an automobile and three days' employment of the driver seemed quite liberal and 45c. per mile a rather high transportation rate. But there were compensations. We saved two days' time and traveled when we pleased and stopped where we liked. We could have stopped two or three days longer at the mines or anywhere on the road at an additional cost of $5 per day. We could have made the trip to Skidoo by stage and return for $34 each, a saving of $16 each in money, but we would have been obliged to travel to Ballarat both going and returning and to remain there two nights. The travel would have occupied two days by automobile and two days by horse stage, without opportunity to make the desired stops.

Prior to the completion of the Trona R.R. a motor stage between Johannesburg and Ballarat and a horse stage between Ballarat and Skidoo were operated by Rinaldo & Clark, of Johannesburg, and since the completion of the railroad the auto stage runs between Johannesburg and Trona, connecting with trains, and thence between Trona and Ballarat. The horse stage still operates from Ballarat to Skidoo, but arrangements can now be made for direct service between Skidoo and Trona. Ballarat is 20 mi. northeast of Trona and several miles off the direct road through Panamint Valley to the Skidoo district. The Trona R.R. connects with the Southern Pacific (Olanche branch) at Searles station, 12 mi. north of Randsburg. There is no stage connection between Randsburg and Searles, but special auto service can be provided.

Some Visits Made Conveniently Afoot

Much of the visiting at Randsburg and vicinity, including the Yellow Aster, the Consolidated, the King Solomon, the Butte and the Phœnix mines and the Phœnix and Red Dog mills, was done afoot, where an automobile would have been practically useless. It can be done with less effort and about the same speed by saddle horse, but if your legs are good you had better use them and not bother with a horse. The cost of automobile travel in Randsburg and Stringer districts was not enough to warrant the time and worry of finding and trying out a cheaper mode of transportation. One day we covered a large amount of ground by automobile and afoot at a cost of $7.50 each. On two half-days we accomplished a surprising amount of work by automobile at a total cost of $8.50. The journey from Randsburg to Mojave, a distance of 60 mi. over the worst sand road in these entire regions, cost us a total of $25. We started at 7 a.m., stopped five or six hours at the Consolidated Salt Co.'s works and at the California Gypsum and Hollow Tile Co.'s plant, and arrived at Mojave at 3:30 p.m. We used the Overland in actual service six days, traveling 430 mi., for which we paid $172—an average of 71.5 miles a day at an average rate of 40c. per mile. Including one day's layover at Skidoo and one day spent overhauling the machine, Neihaus was employed a total of eight days, making his average earnings $21.50 per day. The higher cost in the Mojave district and the Yuma region brought the average cost for the entire trip to 42.5c. per mi. This rate should be lowered on a second trip, but there is no certainty that it would be.

Immediately upon arriving at Mojave, we engaged a Buick and driver at the outrageous rate of $4 per hr. for a short visit to the Mojave Consolidated mine, four miles distant by fair road. The travel occupied about 30 min. and we were at the mine about an hour and a half. Wolflin made another visit to the Mojave on the following day and the next day visited the Tropico mine at Rosamond, 15 mi. south of Mojave, with the same automobile at a more reasonable rate. I was due at San Bernardino on the day following our arrival at Mojave and left on the Santa Fe at 2:45 a.m., arriving in time for breakfast; Wolflin joined me three days later.

We left San Bernardino by evening train on the Southern Pacific, arriving at Yuma about midnight. We immediately engaged a Reo machine and driver at a cost of $25 to carry us the next day to the American Girl and Tumco mines in Imperial County, Calif., 20 mi. northwest of Yuma. We could have made this trip by horse stage from Ogilby, a station about seven miles southwest of the mines on the Southern Pacific, but owing to lack of hotel accommodation it would have been necessary to go

to Yuma and then return next day by rail to meet the stage at Ogilby. This meant over night at the mines, where there is no hotel. While negotiating for automobile service we were informed that the mines were 39 mi. distant from Yuma. We knew from the Geological Survey Yuma quadrangle that the American Girl mine is 9 sectional miles north and 11 sectional miles west from Yuma and that the Tumco mine is just 2 sectional miles farther north and the same distance farther west. Anyway, the automobile hire would be $25.

When ready to start in the early morning, there was delay due to the assembling of a committee of citizens in two other automobiles, who were going along to view out a new and shorter road to the mines, and we were supposed to follow them and make the travel easier for ourselves. Of course we did not follow them. They followed us. That is why we waited for them. Our driver knew the way because he and his business partner had been traveling this new road and some parts they had pioneered. The fact is, that after crossing Colorado River we followed approximately the road delineated by the Geological Survey 10 years ago, though some shorter cuts had recently been made and others were being tried out. The road mentioned as being 39 mi. long is the road to Picacho mine, 20 mi. almost due north of Yuma, from which a branch road runs west and through the cañon to the American Girl. The distance to the Tumco by this road is about 30 mi., but by the road we traveled not more than 20 mi.

I returned to Yuma in the automobile that afternoon, making the run from the American Girl in about an hour and a half, and that was lively going considering the character of the road. I ventured to express surprise at the speed we were making after I had stood about as much jolting as I thought was due, and was informed that the buoy ferry quit running at 5 o'clock, and if we did not beat it we would have to walk across the railroad bridge. Loss of one minute caused us to walk the bridge. Yuma goes by the clock. Wolflin stayed over to complete his work and went out (at a cost of $2), by horse stage, which takes 2½ hr. from Tumco, and connects with the westbound Southern Pacific passenger train about noon at Ogilby.

The mines are situated each in a broad cañon at an elevation of 700 ft., surrounded by hills that rise to a maximum elevation of 2,225 ft. above sea level. There is a gradual slope from the mines to the north bank of Colorado River, where the Survey bench mark at Rio indicates an elevation of 156 ft. Yuma elevation is 137 ft. at the station and 297 ft. one mile south. This is sure enough desert country. Nobody denies it, but nobody responsible for Yuma complains about it. In the old burro and horse-stage days the people moved slower, but they lasted longer. Looking back over a period of 20 years, I recall that the Yuma people I knew in that day were as progressive, considering the means at hand, as they are today. But the automobile is broadening the trail in this, as in other desert regions. There are many roads in this region that only an experienced automobile driver can get over in any type of machine.

The Marketed Production of Silica in the United States in 1914, as reported by the United States Geological Survey, amounts to 181,731 tons. This includes the production of silica from vein quartz, pegmatite and quartzite, and the output of tripoli and diatomaceous earth.

The Juneau Gold Belt*

The Juneau gold belt comprises a mainland strip running from Windham Bay northwestward to Lynn Canal and Berners Bay. It contains some mines and prospects south of Juneau, those in the vicinity of Juneau, including Douglas Island, those in the Eagle River and Yankee Basin regions and those in the vicinity of Berners Bay. The geology and mineral resources of this region have been described in full by Spencer[1] and Knopf.[2]

The developments near Juneau, because of their magnitude, overshadow the operations in other parts of the gold belt, yet some of these are of importance. The active small-scale mining and milling operations that were conducted a few years ago in the Eagle River and Berners Bay districts have recently experienced a decided falling off, due in part to the failure of some of the properties to meet expectations and in part to consolidations preliminary to operations on a larger scale.

Gold lode mining in this field, already developed on a scale that ranks the Juneau district with the foremost in the industry, is rapidly assuming still greater proportions. The growth is a natural response to a fuller knowledge of the size and character of the orebodies and the economic possibilities of large-scale operations.

Climatic conditions are favorable to continuous operation. The large size of some of the orebodies, the physical character of the ores and a strong topographic relief favor the production of large quantities of ore with a minimum of labor and power. Water power, marine transportation and a local supply of timber and lumber reduce general expenses to a low point. The extraordinarily low costs of operation make available low-grade ores that under conditions only slightly different would be valueless. The milling operations in the vicinity of Juneau, in 1914, were equivalent to the constant operation of about 1,000 stamps. Mining and milling operations combined gave employment to an aggregate of about 2,250 men.

Chino Copper Quarterly Report

The Chino Copper Co., working at Santa Rita, N. M., reports for the third quarter of 1915 a gross production of copper in the concentrates of 18,545,638 lb., divided as follows: July, 6,650,429; August, 6,640,923; September, 5,254,286. The total tonnage of ore treated for the three months was 690,400 tons, an average of 7,504 tons per day. This is the highest average tonnage treated by the mill since the beginning of operations. The average copper content of the ore treated in this quarter was 1.98%, against 2.38% for the previous quarter. The average extraction for the third quarter was 67.82%, as against 65.34% in the previous quarter.

The cost per pound of net copper produced for the quarter, after allowing for smelting deductions and crediting all miscellaneous income, was 7.18c., as against 6.10c. for the second quarter and 6.38c. for the first quarter. The increase in cost per pound is due to the fact that the average grade of the ore was lower during the third quarter, with a resulting lower recovery in pounds per

*Excerpt from Bull. 622-C, U. S. Geological Survey, entitled "Mining in the Juneau Region, Alaska," by Henry M. Eakin, 1915.

[1]"The Juneau Gold Belt, Alaska," U. S. Geological Survey, Bull. 287, 1906.

[2]"Geology of the Berners Region, Alaska," U. S. Geological Survey, Bull. 446, 1911; "The Eagle River Region, Southeastern Alaska," U. S. Geological Survey Bull. 502, 1912.

ton of ore. These costs include all operation, administration and general charges, and the regular charge of 30c. per ton of ore treated, for the extinguishment of mine development and stripping expense.

The net profit from milling operations for the quarter was $1,503,846; miscellaneous income, $51,568; a total of $1,555,414, on which dividends were paid of $652,455, leaving a net surplus over dividend requirements of $902,959.

The earnings for the quarter were based on 16.003c. per lb. of copper, as against 17.54c. in the second quarter, and 14.37c. in the first quarter. All unsold copper on hand and in transit is inventoried at 14c. per lb. During this quarter there was moved a total of 1,222,097 cu.yd. of material in place, as against a total of 1,208,360 cu.yd. for the previous quarter. Of the total amount of material removed for this quarter, 841,055 cu.yd. was stripping, the remainder being equivalent to 724,723 tons of ore.

Utah Copper Co.'s Report

The Utah Copper Co. reports for the third quarter of 1915 a production of 44,766,841 lb. of copper, divided as follows: July, 14,641,009; August, 15,966,543; September, 14,159,289. The production in the second quarter was 40,799,825 lb. During the period in question a total of 2,498,400 tons of ore was treated, which was 283,241 tons more than the previous high record of the preceding quarter. The average grade of the ore was 1.4089% copper, as compared with 1.42% for the second quarter of the year, while the average extraction was 63.59%. The low extraction was said to be due partly to the presence in the ore of considerable copper in the form of carbonate, but principally to the unusually large tonnage treated.

The average cost per pound of net copper produced during the quarter, after allowing for smelting deductions and without crediting miscellaneous income, was 7.64c., as compared with 7.19c. for the second quarter of 1915. If the net miscellaneous earnings in Utah, including those from the Bingham & Garfield Ry. were credited to the cost of operations, the net cost would be 6.76c.

Earnings for the quarter were as follows: Net profits from milling operations, $3,663,708; other incomes, rent, etc., in Utah, $25,668; income from Nevada Consolidated Copper Co.'s dividends, $375,188; Bingham & Garfield Ry. Co.'s dividend, $350,000; total net profits, $4,414,564, from which dividends of $1,624,490 were paid, leaving $2,790,074 surplus. Earnings for the quarter are computed on the basis of 16.252c. per lb. for copper, as compared with an average price of 16.984c. for the preceding quarter. All unsold copper on hand and in transit is carried in inventory at 13½c. per lb.

The daily average of ore treated for the quarter was 27,157 tons. Of the total tonnage for the quarter the Magna plant milled about 60%, and the Arthur plant about 40%. During the period under review there was removed a total of 1,617,779 cu.yd. of capping, as compared with 1,548,432 cu.yd. removed during the second quarter of 1915. The Bingham & Garfield Ry. handled an average of 17,856 tons of ore per day from mine to mill, as compared with an average of 16,798 tons for the preceding quarter. An average of 4,269 tons of other freight was transported, as compared with 2,921 tons per day for the second quarter of 1915.

Tin Mining in Alaska*

The first discovery of stream tin in Alaska was made by the Geological Survey in 1900, on Buhner Creek in the York district, which occupies the western extremity of Seward Peninsula. In 1901-02 considerable prospecting for stream tin was carried on, the first commercial production of tin ore being made in 1902. From that time until 1911, when the first tin dredge was installed, the placers were worked on only a relatively small scale. Since 1911 the dredge on Buck Creek has operated successfully each season, and in 1914 two dredges were installed on Anikovik River, for the recovery of gold and tin together.

Lode tin was first discovered at Cape Mountain in July, 1902, and lode mining has been carried on to a greater or less extent ever since. Stream tin has also been found in different parts of Yukon Basin—on Cleary and other creeks of the Fairbanks district in 1904, in the Circle and Hot Springs districts probably in 1908, and in the Ruby district in 1912. There has been no com-

* Locality where tin has been mined ■ Locality where some tin has been found

MAP SHOWING ALASKA TIN DEPOSITS

mercial development in any of these fields except in the Hot Springs district.

Since the discovery of tin in Alaska, a total of 526 tons of metallic tin had been produced to Jan. 1, 1915, having a value of $380,006. Practically all the tin mined in Alaska has been shipped abroad for reduction. The earlier shipments went mainly to Swansea, Wales, but lately a large part of the production has been sent to Singapore, in the Far East.

Tin Mining in the York Region

Tin ore in both lode and placer form is broadly distributed in the western part of Seward Peninsula, but commercial development has taken place at only a few localities. Lode properties have been prospected at Ear Mountain, Buck Creek, Cape Mountain, Brooks Mountain, Lost River and a few other localities of minor import-

*Abstract from Bull. 622-B, United States Geological Survey, 1915.

ance, but the only productive lode mine at present is that of Lost River. Considerable underground work has been done on the Cape Mountain property, but the mine has been closed for several years. Placer tin has been produced in commercial quantities from Buck Creek and from Anikovik and Lost Rivers. Placer operations in 1914 were confined exclusively to Buck Creek and Anikovik River.

The mining activity of the region in 1914 included the operation of three dredges for all or a part of the season, the preparation of a tract of tin-placer ground for the installation of an additional dredge, and the operation of the Lost River lode mine and mill. About 40 men were engaged directly in mining operations—20 men on Buck Creek, 5 on Lost River and 15 on Anikovik River, where two dredges operated for both tin and gold. About 25 men were also employed temporarily in the construction of the new dredge on Anikovik River. The only winter mining done in the district was at the Lost River mine, where three men were employed.

Lost River is a small stream that heads in the York Mountains and flows southward into Bering Sea, about 10 mi. east of Cape York. Freight charges from Seattle, including lighterage at Lost River, on ordinary merchandise are $12.50 per ton. The return freight rate on ore shipments is $15 per ton.

The general country rock is limestone, and there are a considerable number of vertical quartz porphyry dikes piercing the limestone. A few of the quartz porphyry dikes are highly altered and contain more or less of tin and tungsten minerals. Two dikes of this character, known as the Cassiterite and Ida Bell lodes, are being explored and developed by the Jamme Syndicate as the Lost River mine.

Tin Placers on Buck Creek and Tributaries

Placer tin occurs on Buck Creek for its entire length, about 4 mi., and on Sutter Creek and Left Fork, its principal tributaries. Gravels of Grouse Creek are tin bearing for over ¼ mi. below the mouth of Buck Creek.

Cassiterite occurs in bedrock in three ways in the Buck Creek area: As an impregnation in quartz porphyry dikes; in quartz stringers cutting the slates; and intergrown with arsenopyrite in a gangue of radial actinolite. The chief source of the stream tin is the abundant quartz stringers of the Buck Creek areas, being supplemented somewhat by the other forms of bedrock deposit.

Commercial tin placers have been developed for about 3¾ mi. along Buck Creek, and for over ¼ mi. on Grouse Creek below the mouth of Buck Creek. The development work includes drill prospecting, opencut mining and dredging. About 1½ mi. of the placer had been mined out at the close of the 1914 season. The average depth to bedrock on upper Buck Creek is only 4 ft. Downstream the depth increases slightly, and at the mouth of Sutter Creek and below it is 5 to 6 ft. The width of the placer is 60 to 200 ft.

The concentrate derived from placer operations contains cassiterite, sundry heavy iron minerals and a little gold. The average metallic-tin content of the concentrate is reported to be about 60%. The gold content is worth only a few dollars a ton, and so far it has not affected the selling price of the product.

In 1914 the American Gold Dredging Co. put two dredges into operation on the lower Anikovik. One of the dredges, formerly on Peluk Creek near Nome, was moved along the coast of Bering Sea intact, and was made to ply its own way across the bar into the mouth of the river. The other dredge was new and was installed on an artificial pond ¼ mi. from the beach. These Anikovik River placers are shallow, ranging generally between 6 and 8 ft. in depth. The chief value is in their gold content, but sufficient tin is present in them to make a valuable byproduct.

Placer Tin in Hot Springs District

Placer tin, accompanying placer gold, was discovered on Sullivan Creek in the Hot Springs district, probably in 1908. Gold mining in the district developed rapidly, but in the earlier mine development no attempt was made to save the tin ore. During clean-ups more or less of tin concentrates were thrown aside and disregarded until 1911, when 1,200 lb. was collected and shipped. The ore was found to be of high quality, and the returns from the small shipment directed attention for the first time to the possible value of tin as a byproduct.

The freight rate on tin ore from Hot Springs to Seattle is not definitely known, but it probably does not exceed $55 per ton, which is the tariff on ordinary merchandise. The shipments from Seattle to Singapore in 1914 were charged approximately $15 per ton.

The known area of occurrence of cassiterite in the Hot Springs district coincides in general with that of the productive gold placers of the Sullivan Creek Basin. The general placer zone is about half a mile in maximum width and extends for about 6 mi. from Upper Cache Creek to Woodchopper Creek.

Prospecting for Lode Tin Deposits

The local derivation of the tin ore should be emphasized, on account of the belief current in some quarters that the material of the placers has come from the vicinity of Roughtop Mountain, a belief that has led to much apparently useless prospecting for lode deposits at that locality. The so-called prospects near Roughtop Mountain were examined and samples taken, which, being tested chemically for tin, gave no trace of the metal. The prospect pits were sunk on what appears to be the ordinary country rock in a more highly altered phase near its contact with the intrusive granite. Nothing resembling the tin ore of the placers was found, nor anything that suggested the presence of cassiterite in any other form. Prospecting for tin lodes should be done in the bedrock in the vicinity of the placers, especially of the placers that contain many angular, slightly worn ore fragments. It seems certain that the bedrock source of much of the tin is to be found between Sullivan Creek and the north margin of its drainage basin, west of Quartz Creek. Whether lodes of commercial value occur in this area can be determined only by an examination of the bedrock, a difficult and expensive matter except in the mine workings or along the ridge tops, because of the thick accumulation of alluvium and rock waste.

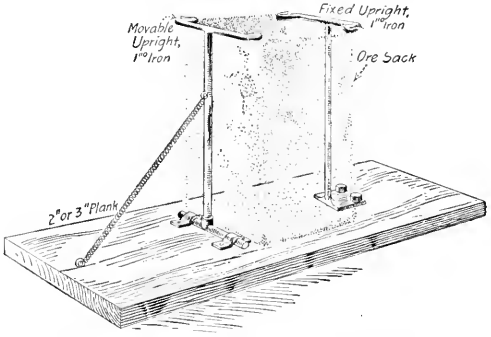
Iron-Zinc Alloys—F. Taboury (Comptes rend., 1914, 159, 241-243; abstr. "Journ. Soc. Chem. Ind.") states that crystalline deposits from galvanizing baths, separating somewhat above 422° C., were in all cases constituted of solid solutions containing 7.3% Fe. There was no evidence that these reacted with zinc at a lower temperature, even when slowly cooled, to form mixed crystals containing 0.7 Fe

Details of Practical Mining

Simple Holder for Ore Sacks

The time required for filling ore sacks is to a large degree dependent upon the rapidity with which a filled bag can be removed and an empty one put in place for the shoveler and by the effectiveness of the device used to hold the sack open and upright while it is being filled. The accompanying sketch shows a simple device (used at the United Verde mines at Jerome, Ariz.) that fully meets all the requirements of a good holder and can be easily and quickly made by any blacksmith from materials to be found at any mine, whether operations be on a large or a small scale.

The base for the bag holder is a 2- or 3-in. plank 12 in. wide and 5 or 6 ft. long, to which, as shown in the illustration, are attached two uprights of iron, each of which has a horizontal top piece curved to resemble a horn



DEVICE FOR HOLDING ORE SACKS OPEN DURING FILLING

and sharpened at the end to grip the material of the sack. One upright is secured rigidly to the base board, while the other is attached to the base by a spring, at such distance from the fixed upright that when both are in a vertical position a bag or ore sack will hang between them when the open end is supported by the horn-shaped pieces. A coil spring, one end of which is attached to the board and the other to the movable upright, stretches the opening in the sack and holds it for easy filling.

Cheap Distillate for Oil Engines

In the Piñon Range, Eureka County, Nev., during the sinking of a 900-ft. shaft a 60-hp. Fairbanks-Morse, horizontal, one-cylinder, 4-cycle, oil engine and hoist combined was used. This was belt-connected to an Ingersoll-Rand Imperial 2-stage air compressor, 12x7½x12-in., capacity 310 cu.ft. per min.

This "oil engine" in that district was an innovation. The fuel used (variously known as "slop distillate," "No. 2 Tops" and "stove oil") was purchased of the Union Oil Co. as "stove oil," gravity of 32° Bé. guaranteed. This oil was invoiced at 3c. per gal. and the total cost laid down at the shaft was 8c. per gal.

The use of this low-grade fuel for internal-combustion engines is desirable chiefly because of the saving in cost over distillate. It is very satisfactory for use in pulling a steady load such as the compressor. When handling variable loads, as in hoisting, it does not give the satisfaction hoped for. When picking up the loaded bucket from the bottom after running "light," the engine is apt to be "killed" or miss explosions. The engineer must then leave his hoisting levers, run around to the throttles and, after adjustment, run back again. Unless he be of a specially conscientious disposition he does not run, but walks leisurely, thus losing time and boosting costs.

Speeding Up the Plane Table

By R. T. Hancock*

The use of a plane table provided with a telescopic alidade fitted with stadia points and vertical arc enables detail mapping to be done with a speed, accuracy and economy scarcely obtainable by any other means, but the weight of the alidade, concentrated as it is near one end, makes it awkward to handle, and there is difficulty in keeping the alidade edge accurately aligned on the station dot. Moving the heavy end is liable to throw the table out of orientation, and repeated trials are often necessary before the dot and the edge are near enough together to enable a ray to be drawn by inclining the pencil more or less.

The following described device overcomes all this trouble and greatly increases the speed and accuracy of the work. The alidade is placed on the board, pointing in the required direction, with its edge an inch or so from the station dot. By a single sweep of the light end—the alidade naturally revolving about its center of gravity—the distant rod is sighted and read, and a celluloid set-square, about 12 in. long and cut to an angle of about 10° or so, is laid against the alidade edge with its butt away from the observer and slid along till its outer edge is in alignment with the station dot. This is easily seen, as refraction causes the dot to jump, directly the transparent celluloid covers it. The scale is then brought up against the celluloid with its zero corresponding to the station dot, the celluloid slipped out of the way, and the distance as read by the stadia pricked off, giving the location of the rod on the map.

Assuming that, with a telescopic alidade used without this modification, the collimation line of the telescope lies exactly above the alidade edge and parallel to it—a combination rarely to be found—all the lines on the map are accurately parallel to the corresponding lines on the ground when the table is correctly oriented. If the collimation line is not thus parallel to the alidade edge, but makes an angle with it, all the lines on the map will be

*Jemoa, Northern Nigeria.

inclined at this same angle to their originals on the ground when the table is correctly oriented, but no error or distortion is introduced into the work, as the orientation was done under the same conditions of eccentricity. The use of the supplementary celluloid demands, therefore, that the table should be oriented by its means.

Resecting and Locating

In resecting from three fixed points already marked on the map, the celluloid is laid against the magnetic meridian as drawn, in the same manner as it is laid against the alidade edge, the trough compass laid against its outer edge and the table swung till the needle points to zero. The alidade is then laid pointing to each station in turn, but with its edge an inch or so from the corresponding dot, the distant station sighted by a sweep of the alidade, the celluloid brought up into alignment with the dot as described, and the back ray drawn. Some little extra care may be taken here to keep the distance between alidade edge and station dot reasonably uniform in the three cases. The triangle of error, if any, is eliminated in the usual way. If preferred—but the surveyor who has once used the "celludade" will not prefer it—the table can be oriented in the usual way by the alidade alone, and when the resection point is accurately found, the celluloid and alidade are brought up together so that the outer edge of the former touches both resection point and the most distant station dot, and the table is swung until the distant station is sighted, leaving the table in correct orientation for subsequent work with the celluloid.

In locating the position of a set-up to which a forward ray has already been drawn, the celluloid and alidade together are brought up till the outer edge of the former aligns with the ray, and the table is swung till the back station is sighted. The alidade is then laid with its edge an inch or so from another station dot, the original of which is visible from the set-up; the telescope sighted on that station by a swing of the light end of the alidade; the celluloid slid up into alignment with the station dot; and the back ray drawn, fixing the position of the set-up on the map by its intersection with the first ray and leaving the table with the required orientation.

It will be noticed that in working with the celluloid it is never necessary to move the alidade bodily while observing or to trouble to keep its edge against a particular dot—a point which surveyors who have worked with a heavy alidade will appreciate.

The error introduced by the employment of the celluloid is extremely small and amounts to an actual error in the location of a fixed point on the ground equal to the difference between the distance of the dot from the real alidade edge used for that particular fix and the distance which may be regarded as the normal distance of the dot from the edge, which latter has been referred to throughout this article as an inch or so. It is similar to, but much less in amount than, the error introduced by not centering the station dot accurately over the station, a detail which is usually regarded as a needless refinement in plane-tabling.

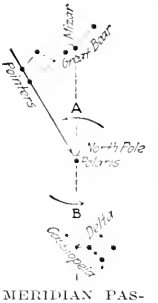
A specially cut set-square is not really necessary, but its cost is so trifling that it is well worth getting. An ordinary large 60° set-square can be used, but the consequent skew of the map as compared with the ground as it lies before the eyes of the surveyor is a little disconcerting at first.

Azimuth by Simple Method

The usual method of obtaining azimuth from Polaris is by making observations at elongation. The following method, not new but little known, will be found much simpler in application and fairly accurate. No instrument and no nautical alamanac or mathematical tables are needed.

This method is based on the fact that Polaris and two adjacent bright stars are in the same vertical plane only a few minutes before Polaris crosses the meridian. It can be used at only one moment in each 24 hr., and a fairly clear sky is required to enable the stars to be sighted behind a plumb-line. The two stars that can be used in this observation are Mizar, the middle star in the tail, or handle, of the Great Bear, or Dipper; and Delta, in the constellation Cassiopeia. The former can be used only when it is below the pole during the night; when it passes the meridian above the pole it is too near the zenith to be of service, in which case the latter star is observed. The accompanying diagram shows the principal stars of the constellation of Cassiopeia and the Great Bear, with Delta Cassiopeia, Mizar and Polaris on the meridian. The table shows the exact time at which these stars are in the same vertical plane on given dates. The time for other days can be secured by direct interpolation, the daily variation being 4 min. of time.

OBS. ON MIZAR		OBS. ON DELTA CASSIOPEIA	
Jan. 20	5:22 a.m.	July 20	5:30 a.m.
Feb. 20	3:20 a.m.	Aug. 20	3:28 a.m.
Mar. 20	1:30 a.m.	Sept. 20	1:26 a.m.
Apr. 20	11:24 p.m.	Oct. 20	11:24 p.m.
May 20	9:26 p.m.	Nov. 20	9:22 p.m.
June 20	7:24 p.m.	Dec. 20	7:24 p.m.



MERIDIAN PASSAGE OF POLARIS

When it has been determined by observation that Polaris is in the same vertical plane with one of these stars, it can be shown that it will pass the meridian 1.8 min. later during 1915. This interval is increasing from year to year at the rate of 0.33 min., so that in 1916 the interval will be about 8.14 min. The observation can be made either indoors or out by suspending an ordinary plumb-line and marking the direction of the meridian by setting a second point at the stated interval after the two stars are in the same vertical plane.

*J. A. Macdonald, Topographical Surveys Branch, Ottawa, Ont., Canada, in "Engineering News," Oct. 21, 1915.

Accident Prevention During Construction Work

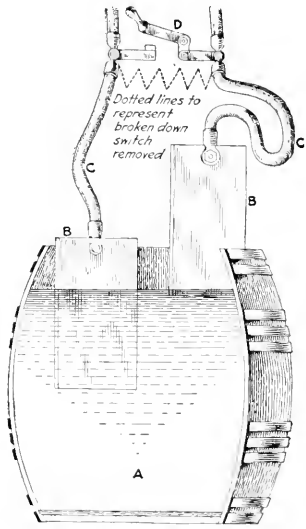
During the construction of industrial plants, one of the most productive sources of accidents is improperly built scaffolding. Scaffolds are frequently built of any sort of lumber that is quickly available for the purpose, whereas only first-class material, free from knots, should be used. Generally, anything from a single board up that will meet the need of the immediate moment is considered sufficient. Serious accidents are often caused by men, particularly iron workers, taking with them heavy tools and equipment, working on a single-plank staging that had been built for the use of one man with no heavy tools. When scaffolds are raised 10 ft. or more above

the ground, they should be provided with toe-boards to prevent the falling of tools and material. When light swinging scaffolds, such as employed by painters, are used, all tools and materials not immediately necessary to the work in hand should be removed from the scaffold.

Working floors should be kept as clean as possible, and all permanent openings should be closed in with planking that is kept in place. These floors should always be made as tight as possible, in order to prevent tools and material from falling through onto men below. All planks on stagings or working floors should be fastened so that a man stepping on one end will not tip the plank up. Accidents from this kind of trap are almost innumerable.

Improvised Motor Starter*

Some years ago, while in charge of a small repair shop, I was called upon to repair a breakdown. The starting switch of a 100-hp. continuous-current motor driving the coal washers at a colliery had burned out. The coils had



SUBSTITUTE FOR A MOTOR SWITCH

become covered with coal dust and had short-circuited, rendering the switch useless.

The voltage was only 110, so the amperes amounted to 680 on full load. There was no spare switch sufficiently large, and another could not be obtained from the makers for some days. It was necessary to get the plant in operation as quickly as possible, and all sorts of plans were discussed, but it was thought unlikely that it could be restarted within 48 hr.

Some method of doing this work quicker had to be devised and the illustration shows what it was.

A wooden cask *A* was obtained and filled with water acidulated by the addition of a little sulphuric acid. There was no time for calculations, so we erred well on the safe side by adding more than was absolutely necessary.

Two sheet-iron plates *B* about 1 ft. 6 in. by 2 ft. $\frac{1}{16}$ in. thick were cleaned, and holes drilled in the top. By means of pieces of cable *C* and terminals, these were attached to the cables leading to and from the burned-out switch, which was removed. An ordinary knife switch *D*, large enough to take the full current, was also connected with the terminals.

When all was ready the main knife switch was put in, the switch *D* being left open, as shown. One of the plates was placed at once in the water and the other dipped in slowly, bringing it also nearer the first plate until the motor started and got up speed, when finally the plates were brought up so as to touch each other and the knife switch *D* put in. The plates were then taken out of the cask until required again.

Safe Distance for Powder Houses

How far powder houses should be kept away from railways, roads and buildings is set forth in a table drawn up by Col. B. W. Dunn, of the Bureau for the Safe Transportation of Explosives and Other Dangerous

SAFETY DISTANCES FOR EXPLOSIVES STORAGE

Quantity — Blasting Caps, Number		Quantity — Other Explosives, Pounds		Safety Distances, Feet — From Nearest Building	From Nearest Railroad	From Nearest Highway
1,000 to	5,000			30	20	15
5,000 to	10,000			60	40	30
10,000 to	20,000			120	70	50

		50,000 to	60,000	2,920	1,750	1,170
		60,000 to	70,000	3,130	1,840	1,250
		70,000 to	80,000	3,310	1,990	1,330
		80,000 to	90,000	3,460	2,080	1,380
		90,000 to	100,000	3,580	2,150	1,430
		100,000 to	200,000	3,670	2,200	1,470
		200,000 to	300,000	4,190	2,510	1,680
		300,000 to	400,000	4,670	2,800	1,870
		400,000 to	500,000	5,110	3,070	2,040

Articles. The table is published by the Bureau of Mines in a bulletin[1] just issued.

The recommended distances vary with the quantity of explosive to be stored, up to a maximum of 2,000 to 5,100 ft. (from roads and from buildings respectively) for 200 to 250 tons of explosive.

An important auxiliary rule is given by the authors of the bulletin quoted: "No detonator shall be stored within 100 ft. of other explosives underground, or within 300 ft. of other explosives above ground. No detonator shall be taken into any magazine containing other explosives."

A Hydraulic Jack should be filled with alcohol 1 part, water 2 parts, with a tablespoonful of sperm oil added. It should never be filled with water, kerosene or wood alcohol. Water is liable to freeze or rust the jack; kerosene destroys the packing; wood alcohol destroys packing and corrodes the metal.

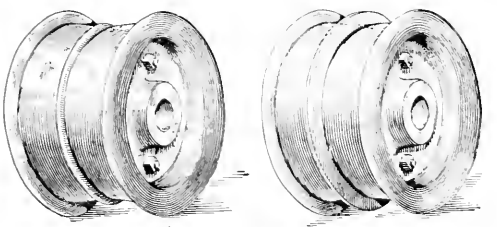
Details of Milling and Smelting

Old Car Wheels as Sheaves

By M. L. O'Neale*

Supplementary to Jesse Simmons' article in the *Journal* of Oct. 16, regarding the use of old car wheels for sheaves and carriers, I would like to give our experiences along this line.

We used these old wheels, that were worn out in the hubs, for sheaves and carriers and in some places for knuckle sheaves, where considerable weight was carried. In this latter case wear was rapid and threatened to use up our stock of discarded wheels. I therefore had our blacksmith make hoops of round iron ($\frac{3}{4}$-in. in our case) with inside diameter equal to the diameter of the worn



SHEAVES FROM OLD CAR WHEELS

wheels at the bottom of the grooves, and as soon as a sheave was cut nearly through, the two wheels were unbolted and this hoop inserted. This gave three wearing points instead of one, as shown in the accompanying sketch.

To accomplish the same result in another case, a circular plate of a diameter a little greater than the wheel was inserted between the wheels, the plate being punched to take the same bolts that held the wheels together.

Turbo-Blowers as Compressors of Furnace Air

The turbo-blower is gaining in favor for blast-furnace and converter work, according to Frederick Laist, who discussed advances in copper smelting before the recent International Engineering Congress at San Francisco.

The new plant at Mt. Morgan, Australia, consists of four turbo-blowers for blast-furnace air and three for converter air, all electrically driven. Each furnace blower is capable of compressing 18,000 to 20,000 cu.ft. of free air per minute to 64 oz. per sq.in. They are each driven by a 500-volt direct-current variable-speed motor. The three converter blowers have a capacity of 5,000 cu.ft. of free air per minute and compress to 12 lb. per sq.in. They are of the latest Parsons multiple-stage centrifugal type.

A new turbo-blower for converter air, having a capacity of 35,000 cu.ft. per min., compressing to 16 lb. per sq.in., has just been installed in the smeltery power house of the Washoe Reduction Works at Anaconda, Mont. It was built by the Ingersoll-Rand Co., and is driven by a Parsons turbine rated at 2,000 hp. when running at a maximum speed of 3,500 r.p.m.

Protecting Reverberatory Walls at Douglas, Ariz.

Forest Rutherford, superintendent of the Copper Queen smelting works, in reviewing[1] the metallurgy of this plant and the changes in equipment, comments on the installation of the reverberatory furnaces because of an increase in the amount of fine sulphides. The slags made are usually high in alumina—11 to 13%—and are rather viscous.

The method of protecting the side walls of the reverberatory furnaces differs from that found at most plants. Practically no barren siliceous material is used. At first, this was the case, but it was soon found that with the very basic slags made, it was too expensive to keep the furnace properly fettled with this material, and also that in dropping it through holes in the roof, along the side walls, there was a great tendency to blanket the bath and thereby reduce the smelting capacity of the furnace.

"A series of experiments was started," writes Superintendent Rutherford, "which ended in our using, for this purpose, ores running as high as 35% Fe, as low as 25% SiO_2, with sulphur from 15 to 18% and copper about 5%. It was, of course, impossible to use this class of material throughout the full length of the furnace, because if used too close to the skimming door, some of it was carried out in an unfused state, making the slags too high in copper. We therefore lined the front half of the furnace with magnesite brick and did not attempt to clay it at all. This method, under our condition, seems to work very satisfactorily. In any case, as far as the method is concerned it is essential that the ore used must contain enough sulphur to matte all the copper, or otherwise it will stay in the slag in the form of prill and be carried out; whereas, if in the form of matte it will go through the slag into the bath below and the slag will be clean."

Electrolytic Antimony Refining

In discussing the conditions for electrolytic antimony refining, Anson G. Betts recently stated to the American Electrochemical Society (San Francisco meeting) that the fluoride electrolyte is preferable to the chloride, as no salt is carried down with the metal in fluoride electrolytes. For easy anode action the solution should contain no sulphates or other oxyacids. For instance, with sulphuric acid there is a formation of antimony sulphate, which quickly forms an insulating coating of insoluble

[1] "Symposium on the Metallurgy of Copper," International Engineering Congress, 1915, San Francisco, Calif.

basic sulphate. In addition, the fluorine anion has a comparatively low velocity, and other anions should be excluded as completely as possible, in order to promote the formation of antimony fluoride. A high hydrofluoric acid content is beneficial. While copper, lead, bismuth and silver are eliminated by electrolysis of impure antimony in a fluoride electrolyte, arsenic is not, nor is gold, so that further experiment is demanded. Mr. Betts suggests that in his experiments traces of H_2SO_4 and H_2SiF_6 may have vitiated the results and also suggests that the effect of alkaline fluorides (including ammonium) should be studied.

Harrison Weir-Flow Recorder

A flow recorder to be used in connection with small V-notch weirs has been designed by the engineers of the Harrison Safety Boiler Works. This device seems to have many possibilities of use in cyanide and other wet metallurgical plants, in hydraulic operations, etc.

There is a float which moves with each change of head on the weir and in turn rotates a spiral cam (laid out according to the law of the weir, $CH^{\frac{5}{2}} = Q$) through a multiplying gear. The cam moves a pen carriage which records on a paper drum the quantities corresponding to each position of the float. Backlash has been eliminated by the use of a cable drum instead of a gear and pinion, while friction has been reduced as much as possible by mounting the spindle of the cam upon antifriction rollers. The pen carriage is provided with large rollers or wheels, which rest upon horizontal ways, so that the cam follower which is attached to the pen carriage moves diametrically to the cam disk. The pen is suspended from the pen carriage so that it rests lightly against the chart drum and can readily be removed for cleaning or renewing the chart.

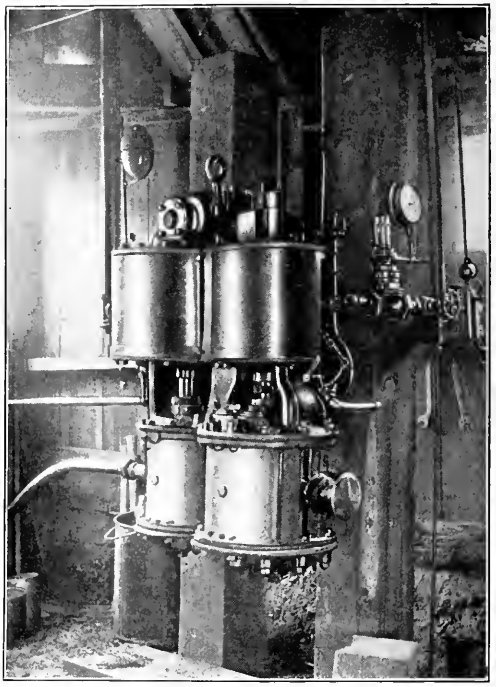
HARRISON WEIR-FLOW RECORDER

An integrating attachment consists of a counting train, likewise suspended from the pen carriage and driven by a small roller which rests upon an aluminum clock-driven disk. When the float and cam are at the position corresponding to the zero head, this roller is at the center of the disk, and hence receives no motion from the rotation of the latter. As the pen carriage is moved away from the zero position, the small roller is carried away the same distance from the center of the aluminum disk, and hence is propelled at a rate corresponding to the rate of flow over the weir. The total movement of the counting train will therefore correspond to the total flow. Further, a visible pointer moving along a large scale with open divisions has been added, making it possible to read the rate of flow from a distance.

All parts of the mechanism of this recorder are made to accurate dimensions by means of templates and limit gages. To be sure of the accuracy of the instrument it is only necessary to know that it is properly adjusted—that is, when the float is at zero position; in other words, when the level of water upon which it rests is at the zero level of the weir, the cam must be at zero position, the pen on the zero line of the chart and the integrator roller at the center of the aluminum disk.

Air Compressor for Prospecting

In prospecting work, when economy is the watchword, it is often possible to make profitable use of a locomotive-type air compressor. This is done at the Columbia mine, Keystone, S. D., where the installation shown in the photograph has been put up. It has a capacity of 151 cu.ft. of free air per minute, and is used for operating jackhamer drills. The machine weighs 1,850 lb. (2,125 when crated for shipment) and is erected on two 10x10-in. posts set 4 or 5 ft. into the ground.



A LOCOMOTIVE-TYPE AIR COMPRESSOR

Roasting Wisconsin Sulphides for Magnetic Separation

The improved Campbell kiln, now operating in the plant of the Linden Zinc Co., Linden, Wis., is making a record in magnetizing the coarse Wisconsin ores for magnetic separation. Recent tests show 10 tons roasted in 3 hr. and 50 min. Other tests show 15½ tons per hr. average run, using only one fuel-oil fire. An average of 8 lb. of flue and smoke-box dust is recovered per ton of ore treated.

The Cost of Doing Things

Cost of Sinking 900-Ft. Shaft

By H. A. Linke*

During the year 1913 an exploratory shaft was sunk 900 ft. in the Piñon Range, Eureka County, Nevada. The general arrangement of the surface equipment is shown in Fig. 1. It consisted of a 60-hp. Fairbanks-Morse horizontal one-cylinder 4-cycle oil engine and hoist combined, belted to an Ingersoll-Rand Imperial-type 2-stage air compressor, 12x7½ in.; capacity 310 cu.ft. per min. The receiver was 42 in. by 8 ft.

The substantial timber headframe had backstays 10x10 and front posts 8x8. The height from collar of shaft to center of head sheave was 50 ft. The hoisting rope was ¾-in. Hercules, "Red Strand." A sinking bucket of ½-ton capacity was used and drilling was done with two Ingersoll-Rand jackhamers.

Two 8-hr. shifts were run, the day shift consisting of 2 miners at $4, 1 topman at $3, 1 engineer at $4.50, 1 timberman at $4 and 1 teamster at $3; and, in the night shift were 2 miners, 1 topman and 1 engineer; making a daily complement of 10 men.

The size of the shaft inside timbers was 3 ft. 6 in. by 7 ft. 8 in., divided into 3 ft. 6 in. by 3 ft. 6 in. hoisting compartment and 3 ft. 6 in. by 3 ft. 8 in. manway and pipe compartment. The shaft was timbered with 6x6 ring sets, 6x6 divider and 6x6 posts; the sets were 6-ft. centers in upper portion of shaft, but lengthened out as ground became firmer with depth; the guides were 4x4. Lumber procured from northern Washington was excellent red fir costing $32 per M laid down.

The cost of sinking this shaft, the excavation for which measured approximately 5x9 ft., is given on page 847.

*Newhouse Hotel, Salt Lake City, Utah.

It will be noted that the work is divided into two separate sections; that is, from surface to 515 ft. and from 515 ft. to 900 ft. When the shaft had reached a depth of 515 ft. the engine house was lost by fire. When sinking was resumed after reconstruction, the footage cost was considerably higher than that immediately preceding the fire, owing to breaking in a new crew of men and the delays incidental to readjustments and repairs to machinery.

The costs given cover only labor, material and supplies used; no overhead charges are included.

The engine cost, laid down at the site, including 5 cooling-water tanks, 1 water-circulating pump, 50 ft. 8-ply rubber belt, tank pump, tools and incidentals was $4,371.05; material in foundation, laid down, $318.52; labor—foundation and installation of engine—$567.18; making the total cost of the hoisting engine complete in place, $5,256.

The engine house was originally a box-type battened building with matched floor and roof covered with roofing paper. This building was easily heated in winter. After the destruction of this building the new shelter was of much cheaper construction—boxed and roofed with red corrugated iron and the floor filled in with fine stuff from the dump. Although the metal-covered house was nearly fireproof, it was very difficult to keep warm in winter and the general unsightliness of a dirt floor did not tend to promote tidiness on the part of the engineers.

The jackhamers used in sinking the shaft were also an innovation in the district. They gave excellent service at a minimum cost for upkeep and repairs. Drilling was performed with two machines, but three were in commission, one being kept clean and in readiness for use as a spare.

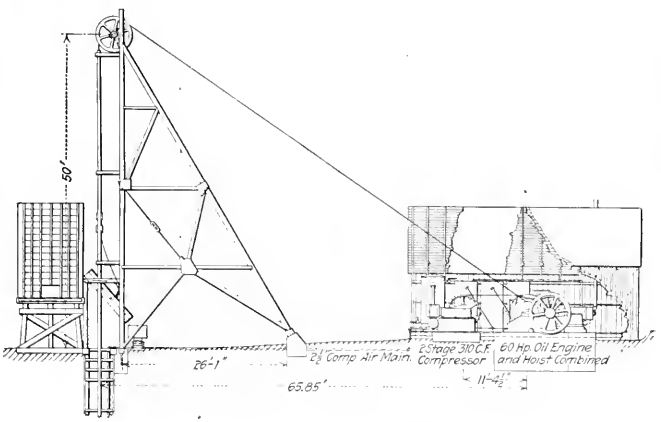


FIG. 1 HEADFRAME AND SURFACE PLANT FOR SMALL EXPLORATORY SHAFT

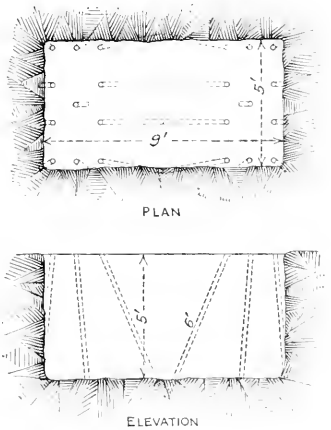

FIG. 2. LAYOUT OF HOLES FOR SHAFT ROUND

The shaft round consisted of from 18 to 22 holes. An average round was drilled approximately as per sketch (Fig. 2).

Electric exploders were tried at first, but those purchased were so unsatisfactory that their use was discontinued and the old-time reliable fire fuse was then used with satisfactory results. The ground was dry and broke very poorly. Being much shattered and faulted, it broke "short" and often to horizontal slips part way the depth

74 feet of drifting, giving average cost per ft. of $10.95.

of the round. The endeavor was to pull a 5-ft. round; the cut holes drilled 6 ft. and the balance of round 5 ft.

Powder of various strengths was used—60%, 40% and 35%. The best all-round results were obtained by loading with 35% throughout. There was 8.4 lb. of powder used per foot of shaft, which is equivalent to 1.45 lb. of powder per ton of rock removed; there being approximately 5.8 tons rock per foot of shaft.

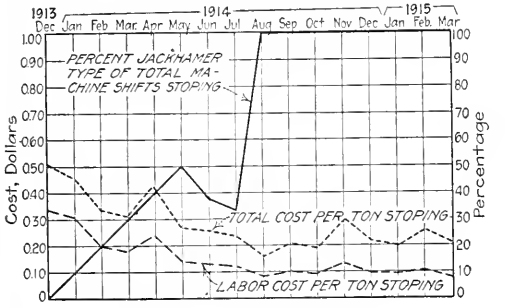
Sinking progressed from Dec. 1, 1912, to July 17, 1913, and from Oct. 18, 1913, to Feb. 21, 1914, or 354 days, at the rate of 7614 ft. per 30-day month. This includes all delays due to repairs and temporary shutdowns due to labor shortage. The first 60 ft. was handwork, using the windlass for hoisting.

The use of candles for illumination when drilling the shaft round was out of the question. The dust raised in drilling and cleaning holes was very thick, and the exhaust from two machines extinguished candles as soon as relighted.

Two Wolf No. 1 carbide lamps were used and gave general satisfaction. As they furnished a very brilliant light, they could be hung high up in links of the chain ladder, beyond reach of the drill exhaust.

Stoping Costs at Iron Mines, Mineville, N. Y.

At one of the large iron mines, Mineville, N. Y., charges to stoping cover the expense of breaking the ore after it has been developed by drifts and raises. The principal labor items so charged are for machine runners and helpers, blasters, roofmen, drill sharpeners and drill-



STOPING COSTS AT MINEVILLE

machine repairs. The principal supply charges are for explosives and compressed air. Therefore the cost per ton for stoping, more particularly the labor cost, is a direct measure of the efficiency of the drilling. There are, however, some fluctuations in the cost curve due to varying tonnage hoisted each month, it being impossible to get the number of tons broken each month from which to derive stoping costs per ton.

The accompanying curves cover a number of months during the period from when we started to use Jackhamer-type machines for stoping up to the present. They give for each month the labor cost per ton for stoping, the total cost per ton for stoping and the percentage of total machine drifts charged to stoping which were Jackhamer-type machines. They show that while the percentage of the Jackhamer type rose from zero to 100% the total stoping cost per ton fell from 51c. to 20c. and the labor cost per ton stoping fell from 31c. to 8c.

Milling Costs in Alaska

The following figures on milling costs were taken from the annual reports of the Alaska Treadwell Gold Mining Co., Alaska United Gold Mining Co. and the Alaska Mexican Gold Mining Co., Douglas Island, Alaska, for year 1914:

	Alaska Treadwell 240-Stamp Mill	300-Stamp Mill	Alaska Ready Bullion Mill	United 700-Ft. Claim Mill	Alaska Mexican Mill
	COST PER TON MILLED				
Crushing	$0.038	$0.037	$0.016	$0.021	$0.022
Tramming	.016	.016	.016	.015	.016
Stamping	.172	.138	.165	.166	.159
Concentrating	.054	.050	.067	.052	.048
Total	$0.280	$0.241	$0.264	$0.264	$0.245
These costs consisted of:					
Labor	$0.110	$0.079	$0.112	$0.099	$0.098
Supplies	.053	.063	.046	.062	.043
Subsidiary accts.	.117	.099	.106	.103	.104
Tons ore crushed	382,652	527,633	233,100	225,214	233,457

There were 33,774 tons of concentrates produced from the ore treated by these mills. This product was treated by cyaniding at a cost of $2.756 for operating, not including general expenses, train service, etc. This cost per ton consists of the following charges only: Grinding, 49.6c.; dissolving, 97.7c.; filtering, 32.6c.; precipitation, 42.6c.; and refining, 53.1c. These charges were made up of $1.271 for labor, 93.1c. for direct supplies and 55.4c. for subsidiary accounts.

Cost of an Electric Iron-Smelting Plant

The electric iron-smelting furnaces at Hagfors, Sweden, are 4.7 m. across the widest portion of the crucible, 14.7 m. from ground to feed floor and 11.4 m. from the bottom of the crucible to the feed floor. Each furnace is fed by three 1,000-kw. transformers. The cost of this installation of three furnaces is given by *Le Genie Civil*, Aug. 28, 1915, as follows:

Foundations	$59,000
Furnaces	61,500
Transformers and accessories	71,000
Crushing apparatus	9,500
Ore and fuel bins	28,000
Pumps and piping	3,350
Grading and industrial railways	9,650
Accessories	1,360
Cost of research and experiment	9,200
Total	$252,560

Cost of Road Building

While carrying on an extensive campaign of churn drilling at Sacramento Hill, Bisbee, Ariz., by the Copper Queen, it was found necessary to do much road building to facilitate moving the drills from hole to hole. Drilling was continued for a period of 22 months.

The cost[1] of the road building for the period was as follows: Labor and supplies, $22,065.77; footage of road, $15,092; cost per foot, $1.02.

The Cost of Unloading Brick at a Salt Lake Valley smeltery was as follows: With labor at $1.75 per 9-hr. day the average cost of unloading brick from gondola and box cars, inclusive of wheeling an average distance of 100 ft. and stacking, was $0.50 per 1000 brick, labor cost only.

[1]From "Churn-Drilling Costs, Sacramento Hill," presented at San Francisco meeting, A. I. M. E., September, 1915.

Correspondence and Discussion

Anaconda's Campaign for Safety First

The editorial on "Anaconda's Campaign for Safety First" in the *Journal* of Oct. 30, 1915, contains some criticisms of matters of "pure statistical practice," which charge us, at least by inference, with certain errors of which we are not guilty.

In taking these matters up in detail, I wish first to call attention to the *Journal's* objection to our practice of determining the accident rate by dividing the number of accidents by 10,000 shifts. The objection is supported by the statement that both the divisor and classification are odd, and that the results obtained cannot, therefore, be compared with figures given by other companies. You also contend that the correct basis is, of course, the number of accidents per 300,000 man-days, basing your contention upon the fact that the United States Bureau of Mines is trying to introduce this system. Subsequently, you discuss "What is a serious accident?" and say that in the statistics we have given we have left you quite in the dark by lumping fatal and serious accidents.

In reply I may say that the data published in the *Anode* are published primarily for the information of the Anaconda Copper Mining Co.'s employees for the purpose of enlisting their interest in our safety-first campaign. It is therefore necessary to present the data that we publish in such form as will be most readily understood by them. Everybody in Butte knows what a "shift" means, and has therefore some comprehension of what is implied by the number of accidents per 10,000 shifts. Should we publish information concerning the number of accidents per 300,000 man-days, I believe there would be many who would not so readily understand what was meant.

In view of the fact that there is no universally accepted standard method of reporting accident data, I do not see how we can report ours so that they will be universally comparable.

In regard to the discussion "What is a serious accident?" there will be found at the head of each monthly tabulation published in the *Anode,* a statement that the accidents considered are those that caused at least a certain number of days' lost time. During the months of January, February and March we classified as serious all accidents that caused the loss of more than 12 days' time, and on Mar. 1 we raised this limit to 14 days' lost time. No correction was necessary to make the accident rates for the months of January, February and March comparable with those of the succeeding months. There is also at the bottom of each tabulation a note giving the number of fatal accidents included in the tabulation and the names of the mines at which they occurred.

In the September number of the *Anode* we published a tabulation showing the accident rates for the first six months of the present year and the decrease in these rates. In this tabulation no separation was made between fatal and serious accidents. Possibly this should have been done, but as I have mentioned, this information was published solely as a news item of interest to employees.

In another paragraph the *Journal* takes our figures giving the number of accidents per 10,000 shifts and by a mathematical process deduces the number of accidents per thousand men employed per year, assuming that each man works 25 days per month and 12 months per year. Then you say, "However, this figure is not comparable with anything else that we know of." May I call attention to the fact that the figure complained of is the result of your own deductions and that we have not used it? As a matter of fact, it is identical with the accident rate per 300,000 man-days, the use of which the Bureau of Mines is advocating, and which the *Journal* previously assured us was the correct basis that all should use.

In conclusion, I may say that the Bureau of Safety of the Anaconda Copper Mining Co. is most anxious to cooperate with all those engaged in this work of preventing industrial accidents. Any information it may have will be freely given to those desiring it, and if the publication of statistical data in any particular or standard forms will assist the work, it will be only too glad to use those forms.

A. S. RICHARDSON.

Butte, Mont., Nov. 5, 1915.

Technical Journalism and Mining Brokers

I have read Arthur Prill's article in the *Journal* of Oct. 16, anent the desirability of mining engineers, as a profession, making serious efforts to better the standard of the mining industry, particularly in relation to promotions. As to the merits of the remedy suggested—a sort of Dun and Bradstreet applied to mining reports, etc.—although most laudable, I am afraid it is lacking the most direct principles for coping with the situation.

In this, as with any other phase of commercial or professional morality, we are confronted with a condition that Tolstoy recognized when he postulated that the evolution of society is based on the evolution of the individual units constituting society. And although it may seem a hard assertion to make, yet the fact remains that the standard of morality existing in regard to mining promotions is a direct reflex product of the standard of morality existing among mining engineers themselves. The one is a corollary of the other. For that matter, in this particular we are confronted with a fundamental of the psychology of morals; for example, that the principles of an aggregate are but the sum of the individual contributions.

Some months ago I received a circular letter inviting me to attend a meeting for the purpose of forming a local chapter of the American Mining Congress. At that particular time there was an effort being made by sundry people, who probably designate themselves as "mining men," to "boom" a particular mining district not a thousand miles from Salt Lake City, the "messiah" of the

movement being a gentleman who has known what it is to be a guest of the authorities at a certain institution of detention. In reply to this invitation I wrote, asking for particulars as to specific directions in which it would be aimed to advance the mining industry and, *inter alia,* what would be the attitude of the organization in the case of some plan being incubated for fleecing the public; whether it would be the taking of a "club" and beating the gentry involved into insensibility, or the attitude of unctuously prostituting the "am I my brother's keeper" query, and sitting back waiting to join in that old, old refrain, "Dilly, dilly, come and be killed," as the old lady plaintively sang to the duck that was marked for the next day's dinner. My letter remained unanswered.

It doesn't take much moral "guts" to speak the truth when the truth fits the situation better than lying, and there is scant credit in being honest and in meeting one's just obligations when the bank account is in a healthy condition. But to tell the truth when it hurts, and to "play the game" when it means practically almost financial suicide, is quite another matter. It is comparatively an easy matter to grow orchids in a hothouse, and there is no great tax on moral effort to restrain from evil under the hypnotic influence of music in a revival meeting. As a matter of fact, however, there is no greater asset that a professional man can have than the justly earned reputation of being straight. True ability is not such a very scarce commodity in these days of intensive technical application, but we have only to follow some lawsuit to be driven to forceful conclusions as to the other phase of the question, for expert services are by no means always "retained"—"bought" would be a more fitting expression.

Some years ago a certain doctor found the plodding life of practicing in a small country town rather hard hoeing. His first choice was for the honorable life, but the financial results were hurting. And so he conceived of a plan to make some easy money, which consisted in floating a company to advertise the curative properties of applying various so-called secretions of certain animal functions to corresponding physical ailments. In about a couple of years this man became wealthy and then withdrew from his publicity campaign and once more entered the professional fold, specializing as a high-class practitioner in a fashionable part of New York. He placated his conscience by the "auto-suggestion" that he diverted from professional morality only once. The burglar or murderer could utilize the same mental palliative with equal justice.

As to the profession of mining engineering, there is a remedy, and although I dislike the rôle of being dogmatic, I believe such remedy leaves no alternative: The formation of a society wherein every member shall place his professional record and moral entrails before a council before admission thereto, and then subscribe to a severe standard of ethics, any deviation from which—which action would be open to the formation of definite charges by brother members—to be erasure from the rolls. And in addition to general ethics, for the members of this society to be governed by a standardization of technique as to reports or the utilization of the name in relation thereto, etc. A society which, by the rigidity of the moral qualifications and deportment imposed would mean something—both to the member utilizing its insignia and to the public. Not necessarily that the fact that a man is such a member would by any means imply guarantee of any technical opinion expressed, for there is too much to learn to hope for any such degree of definiteness; but at any rate we could insure absolute professional honesty.

When, as a profession, we have purified ourselves, we can with good grace take the proper steps to prevent the shyster promoter from prostituting our profession.

Any society, to be worthy of its object, should make its standard of requirements one which a member could utilize with assurance in proffering them to a surety company if applying to such company for indemnity bonds. Such societies would require applicants to place their whole life's record upon the table.

The remedy is simple enough. There is only one question involved: Do we want to "take the medicine?"

Salt Lake City, Oct. 24, 1915. JOSEPH RALPH.

Society Employment Bureau

It is possible the Western Society of Engineers, 1745 Monadnock Block, Chicago, Ill., may attempt seriously the establishment of an employment bureau for the benefit of technical men and employers of technical men.

Active coöperation is desired. We wish to receive from officers and past officers of societies that have made similar attempts the reasons for failure, if failure was met, and what degree of success was encountered. We should like to hear from every man that has any ideas on the subject and we shall not be appalled if the mails are filled with letters of advice or information. We know the task, if properly attempted, is a big one, hence the desire to receive the benefit of experience and information that is certainly available.

The bureau will be run—if it is started—as an adjunct to the society, and there will be no fees to pay. It will be free in every way and designed to take the men out of the hands of employment agencies, which bleed unfortunate technical men that have no other means for securing positions. ERNEST MCCULLOUGH,

First Vice-President, Western Society of Engineers.

Chicago, Ill., Oct. 27, 1915.

Fettling Reverberatories

Referring to the correspondence printed in the *Journal* of Jan. 23 and Oct. 16, 1915, with regard to the first roof-fettling of large reverberatory furnaces, I find that the Charles who was at Cananea is not the Charles who took out the patent, but is a cousin of his and is a brick mason. The name, Harry Charles, was given me under a misapprehension, my informant thinking that I wished to know the name of the patentee, and not of his cousin, who worked for us at Cananea. L. D. RICKETTS.

Warren, Ariz., Oct. 29, 1915.

Fineness of Ore Crushing for Assaying

Remembering that "it is a condition and not a theory that confronts us," I would be very glad to have E. J. Hall give the practical data to show that the decomposition $2NaHCO_3=Na_2CO_3+H_2CO_3$ "is to all intents and purposes complete before any fusion takes place"[1] in an ore-assay fusion. FREDERIC P. DEWEY.

Washington, D. C., Oct. 25, 1915.

THE WORLD'S SUPPLY OF POTASH. 6¼x9¾, pp. 47, paper; 1s. The Imperial Institute, London, S. W. An account of all the more important sources of potash in the world, including the Stassfurt deposits in Germany, which before the war had an almost complete monopoly of the world's supply.

ESTUDIO DE LA FUERZA HIDRAULICA DE LOS RIOS COLORADO, BLANCO Y RIO DE CHIUTA CON ANTEPROYECTOS PARA LA INSTALACION DE CENTRALES HIDRO-ELECTRICAS. By Victor Sintich. 8½x11½, pp. 34, illus., 16 plates. Sociedad Imprenta y Litografia Universo, Valparaiso, Chile.

THE SAMPLING AND CHEMICAL ANALYSIS OF IRON AND STEEL. By O. Bauer and E. Deiss, translation from the German by William T. Hall and Robert S. Williams. 5½x8, pp. 373, illus.; $3. McGraw-Hill Book Co., New York.

This book was originally a compilation of the methods which have been found reliable after several years' use at the Royal Testing Bureau, Gross-Lichterfelde, Germany, but has been amplified by methods tested by the U. S. Bureau of Standards and in the laboratories of the Massachusetts Institute of Technology.

HENDRICKS' COMMERCIAL REGISTER OF THE UNITED STATES FOR BUYERS AND SELLERS. 7¾x11½ in., pp. 1503, leather; $10. S. E. Hendricks Co., Inc., New York.

The present volume is the twenty-fourth edition of this work, which is published annually. It has been thoroughly revised, entirely reset and much new matter added, which will increase its usefulness. The binding has been changed from cloth to Du Pont "Fabrikoid," making a more handsome book, and we also note an improvement in the quality of paper used.

THE RARE EARTH INDUSTRY. Including the Manufacture of Incandescent Mantles, Pyrophoric Alloys and Electrical Glow Lamps. By Sydney J. Johnstone. Also a chapter on The Industry of Radioactive Substances. By Alexander S. Russell. 6x9¾, pp. 136, illus. D. Appleton & Co., New York.

This is the second of a series of manuals of chemical technology, and is essentially of a practical nature, treating especially of the industrial applications of the rare earths. The pure chemistry of these substances is dealt with only in so far as is necessary for properly understanding the nature and properties of the materials dealt with. The chapters are: Thorium and cerium, titanium, zirconium, tantalum and niobium, tungsten, the incandescent electric glow-lamp industry, uranium, vanadium and the industry of radioactive substances.

DETERMINATIVE MINERALOGY, With tables for the determination of minerals by means of their chemical and physical characters. By J. Volney Lewis. Second edition revised. 5¼x8, pp. 155, illus.; $1.50. John Wiley & Sons, New York, N. Y.

This book has been designed for the use of students in determinative mineralogy and also to meet the needs of the geologist and the mining engineer. The tables give the physical and chemical properties of 380 minerals (which the author says is 100 to 150 more than the current textbooks), while the arrangement is such that unknown minerals may be determined quickly and easily. In the system of determination, the general plan of the Brush-Penfield tables has been followed in the main, but there is much condensation and simplification of procedure.

THE MINERAL INDUSTRY DURING 1914. Volume XXIII. Edited by G. A. Roush. 6x9, pp. 998, illus; $10. McGraw-Hill Book Co., New York.

The twenty-third volume of "The Mineral Industry" is the same in appearance and general plan as its predecessors have been. Indeed, it is remarkable, and a tribute to the foresight of the originators of this publication, that during 23 years there has been so little change of plan. The twenty-third volume brings forward some new contributors, which add freshness to the volume, but in general they stick to the same lines that the writers on the same subject in the past have followed.

The new volume is rather marred by some carelessness in editing. Some of the bibliographies are sadly incomplete, which excites the suspicion that this failing may be general throughout the book. Also, the references to original sources of information in the footnotes are not well done. Many important references are omitted, while minor ones are included, and citations are made to some sources which are not good authorities. The index to the volume is poor, being only a scant 7½ pages.

These criticisms are not offered in any captious way. The defects that we have remarked are trifling in comparison with the great value of "The Mineral Industry" as a book of reference. For a concise summary of progress in the metallurgic arts, for statistics of production and commerce throughout the world, everybody has acquired the habit of turning to this book and usually is able to find what he wants.

THE THEORY AND PRACTICE OF ORE DRESSING. Edward S. Wiard. 6x9, pp. 426, illus.; $4. McGraw-Hill Book Co., New York.

There have been published a good many books on ore dressing, but nothing previously that is just like this one. The treatises in English, heretofore, have been of the descriptive character. The classic of Prof. Richards was much more than that, being encyclopædic. Wiard's new book differs from its predecessors in not being descriptive to any great extent, but rather advisory. That is to say, it tells mill men how they ought to do things, and gives adequate descriptions of the means how and the reasons why, without wasting any time or space upon machines and methods that have been discarded. In other words, this is a treatise by an experienced mill man, who has written a book just as if he were instructing his own assistants or advising a client. It is about the same thing in the art of ore dressing that Peters' first book was in the art of copper smelting.

Now, this book is by no means perfect. There are many things in it with which other mill men will disagree. There are many things that ought to have been treated, which are omitted or else are mentioned but scantily. When we first turned over the pages we were rather shocked to discover how slight was the attention given to the flotation process, but upon referring to the preface we learned that this omission was intentional. The author said, "It was hoped, also, to present some plans and flow sheets of flotation mills, and a large amount of material was collected; but owing to the litigation on flotation processes this information has been furnished confidentially. For this reason the flotation process has not received the mention that its importance warrants."

Here we have once more the bane of that long-drawn vexatious litigation that casts a shade over technical literature like that of the deadly upas tree.

With our eyes open to these shortcomings, however, we think that most mill men will recognize that Mr. Wiard's book is an important contribution to the literature of ore dressing, and is not only refreshing on account of its novelty, but also is of promise with respect to its practical usefulness both to students and the men who are engaged in the actual practice of the art.

RULES AND REGULATIONS FOR METAL MINES. By W. R. Ingalls, James Douglas, J. R. Finlay, J. Parke Channing and John Hays Hammond. Pp. 296. Bull. 75, United States Bureau of Mines, Washington.

It would be difficult to find in this country five men more thoroughly qualified by knowledge, experience and judgment than the members of this committee for the work of which this bulletin is the result. Originally appointed in 1906 as a committee of the American Mining Congress, they spent in preliminary studies, inquiries, tentative reports and publications the following five years, during which they received valuable suggestions from their professional brethren and were appointed a committee of the American Institute of Mining Engineers and of the Mining and Metallurgical Society of America—of each of which organizations they were already members. A fourth instrument of publicity was the "Engineering and Mining Journal," which threw open its columns to the various reports and discussions furnished or called for by the committee. This noteworthy wide and enthusiastic coöperation in such an inquiry is of course highly creditable to the organizations concerned. But it is also a striking testimony to the committee that inspired it. These were competent judges, free from self-interest or professional prejudice, able to comprehend and weigh both criticism and controversy and not ashamed to yield to reasonable opposition. It was worth while to give facts and views to a committee that treated its witnesses as friendly advisers, neither imposing oaths upon them nor flinging curses after them; and the result of its labors, as compared with those of other so-called investigating commissions planned, manned and steered by politicians, is an object lesson in sociology. The first chapter of the volume before me, in which Mr. Ingalls recounts simply and without comment the history of the committee and its investigations, is full of significance to one who can read between the lines.

It was to a work thus auspiciously inaugurated and superintended that the United States Bureau of Mines lent its grateful approval and powerful assistance in 1911 by appointing the individual members of this committee its consulting engineers, facilitating their further labors and finally publishing and circulating their report as Bulletin 75 of the bureau. Its late distinguished director, Dr. Joseph A. Holmes, wrote me, not long before his death, repeating an assurance often given before, that it was his earnest purpose to conduct the Bureau of Mines so as not to oppress individual enterprise by governmental inquisition, interference or control, and especially to keep the bureau out of politics. This report conspicuously illustrates that declaration.

Chapter II constitutes the general report of the committee and Chapter III is the committee's draft of a proposed law. The latter would naturally be regarded as the more important, but I am inclined to give that rank to the former, which contains the committee's opinion of its own work. The following passages indicate this opinion:

> We consider our work to be especially of educational character rather than anything else. It will be useful in three main ways, we think, as follows: (1) As a basis for state legislation. (2) As a basis for private systems of inspection. (3) As a collection of simple rules for the guidance of everybody engaged in mining. . . .
>
> We consider, however, that the chief usefulness of the code of rules that we have formulated will be to small operators, who frequently engage in unsafe practices without knowing that they are unsafe or without thinking about the matter at all. There is a reasonable hope that our report will be of educational value to all mining operators.

Concerning the first two uses of this code mentioned, the committee can already adduce gratifying instances in the codes of states and the systems adopted by large mining companies. In view of the comprehensiveness, technical thoroughness and wide circulation of the committee's code, it is highly probable, not that any legislature or board of directors will adopt it in full, but that no system will be hereafter adopted without a consideration of this one, and that good reason will have to be shown for any omission, addition or departure exhibited by a new system proposed. Legislators and directors cannot hereafter blunder through lack of warning.

The third, the educational, value of this report is greatly enhanced by the comments interspersed through Chapter III and contained in Chapter V—"Discussions of Certain Matters of Practice." Here the conditions to be met are clearly stated and the reasons are given that influenced the committee's adoption or omission of certain rules. This explanation of omissions is specially useful; for an omission might be simply an oversight; and when a drastic or unwise rule is proposed, it is well to know that such a tribunal has considered and condemned it. Moreover, many things are recommended in these chapters as good, though not codified as obligatory.

In short, the code and comments, taken together, constitute an elementary, practical guidebook that ought to be in the hands of every mine operator. If put into his hands, it will certainly open his eyes and thus get into his head, to the great advantage of his brain! It will teach him to value as well as to frame suitable rules; to welcome gladly suitable laws, to oppose bad ones intelligently. For the book is not dry, but fascinating; not abtruse, but practical; not dogmatic, but suggestive and stimulating.

Indeed, the admirable code of this committee is, to my thinking, far more instructive educationally than efficient administratively. Its weakest part is Section 52, "Penalties," which provides that every violation of this law shall be a misdemeanor, punishable, after conviction in a circuit court, by fine not exceeding $500, or imprisonment in the county jail for not more than six months, or both. The same section makes the owner or operator liable for the damage caused by his own act or neglect, or the act or neglect of any superintendent, foreman or hoisting engineer of any mine. Nothing is said about the legal responsibility of employees for anything whatever, and no penalty is provided for any violation of rules by an employee, except that of an indictment and trial by jury in the county court.

The committee frankly confesses this deficiency in the following paragraph (p. 81):

> The committee has endeavored to place the responsibility for certain conditions and the observance of certain requirements upon those who should clearly be responsible—the operator in some instances, and in others the superintendent or the mine foreman. It is recognized that many accidents are due to the miners themselves, owing to carelessness or recklessness, or willful disregard of safety rules; but it is not practicable to penalize the miners for all of such acts. Of course the miner, as well as the operator or superintendent, is personally liable for the doing of an act expressly made unlawful and the doing of which constitutes a misdemeanor. If a miner persistently violates safety requirements, the operator can terminate his employment, if nothing more; or he may, if desired, report the violation of law to the local prosecuting officer or to the mine inspector. Although the men may not be reached in some instances, it is certainly true that a miner injured by the doing of some prohibited thing—that is, in violating the law—would have no recourse against the operator, which is in itself a penalty of a more or less drastic character.

Bearing in mind that the best code is of no use unless strictly enforced and that such an enforcement means the proper punishment of those violations which do not, as well as those which do, result in injury, we must say that the committee's explanation as to penalties shows the weakness of its code in this particular, beyond the need of argument.

For instance, a miner violates Section 51 by giving an electric shock to a comrade "for fun" or by making connection with an electric current so as to get a spark to light his pipe. No harm actually follows, but just such careless acts should be punished without reference to their results. Yet all that the superintendent can do under this code is to tell the district attorney and the grand jury, and get the miner indicted and tried by jury. True, if he "persistently" does the unlawful thing, the operator may discharge him. And finally, if he gets hurt through his own violation of the law, he certainly cannot get damages from his employer.

I am not so sure of the last two propositions as the committee seems to be. I have known superintendents that did not dare to discharge men under such circumstances for fear of a general strike; I have known many a strike that originated in such a discharge; and I have known boards of directors that rebuked their superintendents for "getting into trouble" by trying to enforce discipline. Finally, as to the "certainty" that a violator of the law cannot recover damages for the direct consequence of his own act, a good many people still remember, as I do, the case of an employee that undertook to destroy a mine building with a dynamite bomb, lost an arm through the premature explosion of the bomb, and got from a terrorized jury a verdict for some $17,000 against the company, for "injuries suffered while in its employ." This verdict was, indeed, afterward set aside as contrary to the evidence, but it served to show the value of a jury trial in such a case, place and time.

Admitting, however, all that the committee says under this head, I must still regard its code as highly deficient in penalties. Yet I can hardly characterize this feature as a fault. The most important work of the committee was to point out dangers and remedies; and the highest function of its report will be to convince even employees that the dangers are real and the remedies wise. After that has been accomplished, both the creation and the enforcement of codes will be easy.

R. W. RAYMOND

Hoover Back to Belgium

Among the passengers sailing for Rotterdam on the Holland-American liner "Nieuw Amsterdam," Nov. 10, says the New York *Times,* was Herbert C. Hoover, chairman of the Commission for Relief in Belgium, who has been in New York for two weeks consulting with his American colleagues on the work to be done during the coming winter. He was accompanied by his wife and his two sons. In an interview just before the steamer sailed, Mr. Hoover said:

We have had to prepare for a year ahead. Belgium has been under occupation and blockade for fifteen months, and there have been no imports and almost complete industrial paralysis and un-mployment among the working classes.

The industrial trades in Belgium were hit the hardest. The agriculturists did not suffer so badly. In Brussels from 30 to 40% of the population is on the bread line. In Liege fully half the population is being supported by the relief commission.

We are faced with the task of obtaining for these people a supply of clothing to tide them over the winter. We want about $5,000,000 worth of clothing or clothing material.

The gratitude of the Belgian people to the United States is pathetic. That is the one country in Europe today where America is popular. The people left in Louvain have renamed a public square the Place des Etats Unis, and several streets in Belgium have been named after President Wilson.

Revision of Mining Laws

The convention of mining men that is to be held in Washington on Dec. 16, 1915, at the invitation of, and under the auspices of, the Mining and Metallurgical Society of America, is exciting a good deal of interest, especially in the West, whence numerous delegations have signified their intention to attend.

The headquarters of the society for this meeting will be in the building of the United States Bureau of Mines, where F. F. Sharpless, secretary of the society, will be present on Dec. 15. A book for the registry of persons attending the convention will be open at that time. The society requests that all visitors will register on that day or the following day.

Report of Ray Consolidated

The report of the Ray Consolidated Copper Co., operating at Ray, Ariz., for the third quarter of the year shows a copper production in concentrates of 14,931,388 lb., divided as follows: July, 4,352,571 lb.; August, 5,581,-731 lb.; September, 4,997,083 lb. In addition to the copper derived from concentrating ores there was a total of 450,966 lb. of copper contained in ores shipped direct to the smelter. The total amount of ore milled for the quarter was 716,241 dry tons averaging 1.659% of copper, as compared with 679,004 dry tons averaging 1.677% for the previous quarter. The milling costs for the quarter were 56.54c. per ton, as compared with 44.53c. for the previous quarter. The average mining and coarse crushing cost of ores milled for the quarter was 70.835c. per ton, of which 4.279c. was the cost of coarse crushing, leaving the net mining cost 66.556c. per ton. The underground development for the quarter was 12,205 ft.

The average cost per pound of copper produced from milling ores for the quarter, after allowing for smelting losses and applying dividends of the Ray & Gila Valley R.R. and revenues from gold and silver produced, but no other miscellaneous income, was 10.264c. The combined cost per pound of net copper produced from milling and direct shipping ore for the quarter was 10.294c. These costs include all operating and general charges, as well as 12½c. per ton of ore milled, which is applied to the retirement of mine-development costs. This latter charge is equal to 0.621c. per lb. of copper produced from concentrating ores for the period.

The financial results for the quarter were as follows: Net operating income, $802,775; miscellaneous income, $14,171; less bond interest, $35,675, and dividends, $547,-802, leaving a net surplus over bond interest and dividend requirements of $233,470.

Costs and earnings were adversely affected during the quarter by labor disturbances. These difficulties were fully and satisfactorily overcome by the middle of July, but the organization did not regain its former efficiency for some time thereafter.

Largest Electric Locomotive in the World

BUTTE CORRESPONDENCE

The first of the electric locomotives for use on the division of the Chicago, Milwaukee & St. Paul lines between Deer Lodge and Three Forks, Mont., arrived in Butte Oct. 25 and was viewed by hundreds of interested spectators. The locomotive is the largest electric railroad engine in the world. It was built by the General Electric Co. and is to be taken to the Coast and exhibited at the principal stations along the route.

The locomotives are 112 ft. long, weigh 284 tons each and are designed to use as high as 3,000-volt direct current. Passenger locomotives are geared to haul 800 tons at 60 mi. per hr., and freight locomotives will haul 2,500 tons trailing, on a 1% grade at a speed of 16 mi. per hr. Each locomotive is driven by 8 motors rated at 375 continuous horsepower each. On down grades the train is controlled by reversing the controller, which changes the motors into generators and sends back to the line about 50% of the energy used in pulling a train up grade. This makes the use of air brakes necessary only in case of emergency. The electrification of the 440 mi. from Harlowtown, Mont., to Avery, Ida., has cost $13,000,-000. The first unit completed and to be put in operation will be from Three Forks to Deer Lodge, running through Butte. On Oct. 25, a dozen officials of the Milwaukee and of the Butte, Anaconda & Pacific, with a few guests, made a very successful trial run from Butte to Anaconda and back over the B. A. & P. line. Tests will soon be made with the new locomotives over the line between Deer Lodge and Three Forks, and trains will be running over that division under electrical power by Jan. 1, 1916.

Japanese Mineral Production in August, 1915

Japanese mineral production during August, 1915, according to the Department of Agriculture and Commerce in Tokyo was as follows: Gold, 742,858 kg.; silver, 11,974,036 kg.; copper, 5,667,780 metric tons; iron, 4,986,645 metric tons; coal, 1,290,722 metric tons; crude oil, 43,226,640 liters; sulphur, 6,648,963 metric tons.

Coal and sulphur show a decrease compared with 1914; all others show increases.

Editorials

The Metal Markets

The middle of November sees all of the metal markets in a blaze of glory. In each case there is a large production, probably a phenomenal production, but the demand is so large that the output is readily absorbed on a scale upward. Verily, this is a bull market in the metals.

In copper the strike at the Nichols refinery, reducing the American production of electrolytic copper by about a million pounds a day, gave the market the fillip it needed. Buyers began to think that no matter how plentiful copper might be next year, when Chuquicamata and Inspiration are expected to be going real good, for a while copper might be scarce, especially in view of the facts that producers were well sold ahead and had no great accumulation of stocks. Their thoughts of this nature prompted them to action, and they bought freely.

Some characteristics of the existing copper market are deserving of comment. Buyers appear to have abandoned the policy of coming into the market together, contracting for huge blocks, and then remaining away for a long time. During the last month there has been good business from day to day, each buyer playing his own hand and contracting for copper as he thought it wise to do. On the other hand, producers have displayed no tendency to dangle copper over the buyers' heads, but have supplied it liberally on a scale upward. Not yet has copper been put to an extravagant price.

Within a month the price for lead has risen from 4½c. to 5¼c., the successive advances following large and satisfactory selling at each previous price. The demand for lead, both for domestic consumption and for export, continues large, but in this metal, as in copper, the producers have followed the policy of making hay while the sun is shining and have deemed it wise to convert lead into money as fast as they could.

The demand for spelter appears to be insatiable, for in spite of the rapidly increasing production prices have risen again. The great mystery is how so much of it is being used, for the domestic galvanizing business for peaceful purposes continues all but paralyzed.

Great Britain's Backwardness in Metallurgy

The handicap under which Great Britain and her colonies labor, owing to their small participation in the metallurgical industries of the world—iron and steel excepted—continues to exercise the British press. In the *Journal* of Nov. 13 were reproduced excerpts from a recent article in the *Statist*, which is more rational and better informed than most of its contemporaries. The complaint particularly expressed in this article is against the sending of raw copper from Great Britain to the United States for refining.

This movement, which is no new thing, has not deprived Great Britain of any needed supplies in her time of war, nor has it advanced the price to her. The copper refining business is highly competitive—American, Japanese, Australian, and other refiners meeting in a free field. All that Great Britain loses is the profits that would accrue to her from doing more of this work at home. The reason that she does not do it at home is that her metallurgists are backward, while the blight of labor inefficiency is over everything. In a previous article on this subject, the *Journal* suggested as a fruitful subject for inquiry the reason why Great Britain has been able to maintain her prestige in iron and steel while falling so far behind in copper, lead and zinc.

Opportunities for Unemployed Mining Engineers

Owing to numerous untoward conditions that have obtained in the mining industry for the last few years, there has been a growing number of competent mining engineers who have been finding great difficulty in obtaining employment. This has been adverted to several times in these columns and has aroused considerable discussion. Although the conditions of unemployment have been ameliorated to a certain extent by the present boom in mining, no permanent solution of the problem has been found, and recurrence of these periods of unemployment for mining engineers is a probability.

The field for the independent consulting mining engineer, which was such an attractive one a few years ago, has narrowed almost to the vanishing point. All of the larger mining concerns, which can afford to pay consulting engineers' fees commensurate with the talent required, maintain their own staffs who are constantly employed with the almost innumerable propositions being put to them every year. There is also in these large companies a growing tendency toward promotion and elevation of their own engineers, so that it is increasingly difficult for an outsider to break into these attractive organizations.

Therefore many competent mining engineers are confronted with the question of where to look or what to do. A striking and interesting illustration of the solution of this problem, in one instance, is at hand and should furnish food for thought for others.

About one year ago ten Colorado mining engineers, who had plenty of idle time, organized themselves into a leasing and mining company, believing that if the advice of a competent experienced engineer is sufficient basis for the expenditure of large sums by experienced eastern mining investors, it ought to be sufficient basis for the investment of the engineer's own money. After much consideration of many offerings, a good lease, which each agreed was one he would recommend to a client, was selected near Denver and work was commenced on a comparatively small scale, financed by the engineers themselves, who of course provided the engineering talent for the proposition. Within a very short time they had

found what they went after, and further developments made a paying proposition of the venture. The work is still going on with good results.

If such a scheme were to be as widely adopted as it should be, there would be a dearth instead of a surplus of unemployed mining engineers. There are plenty of promising opportunities, both in new prospects and in old mines whose ores, formerly too low-grade or too complex to be successfully treated, are now profitable. These opportunities cannot be safely judged except by the trained engineer, and this very fact more often brings them to the notice of the engineer earlier than to the promoter or investor. That the engineers have not taken up this independent work and made themselves producers is partly owing to the fact that, when confronted with unemployment, which from previous experience the engineer may know is likely to be quite long, he hesitates about making the venture. However, in one small district, for example, there are more than forty leasers who are making more than $300 a month each, on average veins of ore, with no capital investment. And there are plenty of localities and prospects where a few thousand dollars judiciously expended would at least give a fair run for the money.

The engineers' lease on the Florence, in Goldfield seven or eight years ago, is another instance where engineers took hold of an abandoned lease with the greatest success, although of course in this case it was enlarged by the fact that they were after and found the rather exceptional picture rock which was common to that section of Goldfield in the early days.

Let the engineers grub-stake themselves by association or secure a grub-stake from an outsider and become producers instead of stragglers or farmers.

There is another field for the mining engineer that has sufficient capital to keep himself going for a little while, say 12 to 18 months. If he is not already acquainted with several mining propositions that are being run very unprofitably, a short trip, which would be within his means, would doubtless reveal to him one or more small mining propositions that were producing, say, in the neighborhood of $100,000 a year, whose operations were being sadly bungled. There are hundreds of mining operations being carried on under the direct supervision of men that are not engineers and that have little executive ability and that are not only not producing results but have very little likelihood of ever being able to do so, although the opportunity is there if the right talent be applied. The unemployed engineer could well afford to make a proposition to undertake the handling of such an operation on a contingent basis—not to receive any salary during the period, but to receive a compensation commensurate with the savings or increased profits which he feels his ability will enable him to make over the present poor methods employed. As a consulting engineer he would be staking his reputation, at least so far as his then clients were concerned, on the advice that he would give them as to the methods for changing or improving their mining and milling methods. He would not be doing more or less than this if he assumed this responsibility himself on a contingent basis.

A working arrangement of this kind would be not only mutually advantageous, but also would be as welcome to one party as to the other. A mine that is producing $100,000 a year and that at a loss, will almost never have an engineering staff, nor will it have a head who will feel justified in incurring the expense of employing a consulting engineer to point out where the flaws are that result in unprofitable operations. A mining proposition cannot go on losing money forever, and the limit is much more quickly reached in a mining operation of the size that we have assumed. Therefore the consulting engineer who would attach himself to the company on a contingent-fee basis would be not only a very welcome acquisition from the standpoint of the controlling interests, but under the conditions would be stimulated to put forth his best and most energetic efforts; and there is no doubt that hundreds of mining operations throughout the country which under present conditions are foredoomed to disaster could thus be turned into profitable money-making properties, to the gratification of both parties to the contract.

If these two methods of turning unemployment into employment were to be adopted by any considerable percentage of the mining engineers looking for openings, there would be another great advantage along broad general lines, but in a distinctly different direction. One or two small mines in a district employing, or having in this manner associated with it, a mining engineer would stimulate the other properties that were on a similar basis, both as to size and quality of operations, to make some such arrangement. The eventual result would be that those mining operations, in general, that are conducted on a moderately small scale would be toned up and we should see far fewer monuments to poor engineering and blasted hopes than are now so common in almost every mining district.

Respirators vs. Water Sprays

The danger from the inhalation of rock dust by miners is becoming more and more recognized. The drawing of fine particles of dust into the lungs is not good for the lungs, no matter what be the kind of dust, although certain kinds are less injurious than others. The worst kind is, without any doubt, that which arises when flint or chert is pulverized, as in drilling upwardly pointed holes. The sharp angular fragments, infinitesimal though they be, produce an affection known as silicosis, the sufferer from which is especially subject to tuberculosis. The men working in the zinc mines of the Joplin district of Missouri and in the gold-quartz mines of California seem to be especially subject to this danger.

There are two principal means for the amelioration of bad conditions resulting from the operation of such mines: One is for the miners to wear respirators, in order to filter the dust from the air they breathe. The other is to lay the dust by directing a water spray upon the mouth of the hole being drilled or to use the hollow steel water-drill.

The compulsory use of respirators has been tried by some enlightened operators in the Joplin district, but without success, for the reason that the miners would not wear them except when the shift boss was looking on. At all other times the free and independent miner preferred to be at liberty to converse with his partner, whistle, chew tobacco and expectorate, or do whatever he pleased, rather than protect himself against a danger whereof the consequences were not, anyhow, immediate, so far as he could see. The same aversion used to be observed in

dry-crushing mills, wherein the dust-laden atmosphere was much worse than it is in any mine. No matter how many respirators might be provided, the men would not use them. Sometimes they would tie a wet sponge over the mouth, but generally they dispensed with all protection and tried to lead a merry life, if a short one.

The California mine operators, on the other hand, appear to be having better success in inducing the men to wear respirators than in persuading them to use water in connection with the drilling. The men claim that the use of water in steeply inclined or vertical raises makes some of them very dangerous by rendering the timber slippery and the ground unsafe. Also, they allege that the men who use water in such raises become wet to the skin in a short time and are troubled by rheumatism. The average California miner dreads rheumatism even more than tuberculosis, and as to the latter he does not realize that breathing rock dust may cause it.

This is one of the evils of the mining occupation that cannot be cured effectually by rules and regulations, no matter how many policemen may be appointed to enforce them. The real remedy is education, making the miners themselves see the dangers so clearly that they will want to protect themselves.

BY THE WAY

Recent news dispatches affirm that after a lapse of about two years the service of Pullman cars from Laredo to Mexico City has been resumed. Well and good. But peace and prosperity will seem more assured when the service of man-pushed ore cars is resumed throughout the Sierra Madre.

⁂

The Ford process for producing castings direct "at one heat," concerning which some extraordinary statements appeared in the daily papers, consists chiefly in the delivery of molten pig iron from the blast furnace to the electric furnace through a mixer in the same way as molten iron is delivered to the openhearth steel furnace.

⁂

"The hottest summer known in Alaska, melting the snow on mountain tops for first time since purchase of the territory from Russia, together with the action of a receding glacier, uncovered and exposed near Valdez within 11 mi. of tidewater what is said to be greatest low-grade copper-ore deposit in Alaska." says the Boston *News Bureau*. "Ore zone is 1,000 ft. wide and 3 mi. long. Traversing it are eight strata of schist and quartzite from 24 to 200 ft. in width, freely impregnated with chalcopyrite, carrying values of from 2% to 9% copper. Also in same belt is found great quantity of malachite ore carrying copper value of $10 a ton." There is a long, cold, hard winter coming, however.

⁂

That all the smelter chemists are not rich is merely because they do not know anything to speak of, which is shown by the following quotation from the Salt Lake *Herald-Republican:* "In the smelter fumes are scores of rare materials which as yet the smelter chemists know nothing about. It is probable that in the smelter fumes there are greater profits than in the metals that are being smelted. Take as an example the Tennessee Copper ores—and there are thousands of tons of ore almost identical in Utah—or at least are treated in the Utah smelters. In making its copper the Tennessee Copper saves sulphuric acid, nitric acid, picric acid, tri-nitro-toluol, and other products which will sell under contract during the year for $11,000,000, on which it is declared there is a profit of at least 50%. Using this as a basis for figuring, Utah could produce at its present rate of making copper, $165,000,000 gross. Then there are all the byproducts from the lead-silver stacks which have not yet been taken into consideration. Figuring profits at 50%, the return would be $82,500,000." Let's all start for Utah and get rich.

⁂

The camp of Eureka, Nev., at the height of its activity had a population close to five figures. Austin at this time was compelled to take a back seat; and Pioche crawled into her shell; for twenty years Eureka was the whole show and rejoiced in her prominence. Everything was as rosy as a Flemish sunset; and though Eureka could not hope to rival Pioche in the matter of "men for breakfast," she had enough to maintain a respectable average. Prosperity filled the cup between 1870 and 1890; but after that adversity took to mixing the drinks for the camp—each one a little bit worse than the one which preceded it, writes Charles E. Van Loan in the *Saturday Evening Post*. For the benefit of those who take their narrative sprinkled with names and dates and vital statistics, Mr. Van Loan gives the following thumbnail history of Nevada's lead camp: In 1864 five prospectors set out from Austin, following the Pony Express route eastward to the mountains. On the western slope of the range they found ore that puzzled them; and as they could learn nothing of it by examination they put fragments of it into their camp fire. The result was an immediate flow of whitish metal. The prospectors argued long over it; those who claimed it was silver were told that it was too soft, and those who thought it was lead were told that it was too hard. Both sides were correct—it was a combination of both metals. The news of the strike created little or no excitement. Nevada, with one eye on the tremendous output of the Comstock Lode, could not be bothered with anything so commonplace as a lead mine with silver trimmings. For several years after discovery the district languished while unsuccessful attempts were made to smelt the silver-lead ore; but in 1869 draft and blast furnaces solved the problem, and the camp of Eureka bounced out on the map of the state as the metropolis of eastern Nevada, greatly to the disgust of Pioche, which was just beginning to sit up and howl, a day's journey to the southeast. Foreign capital became interested in the new district. Two mines on Ruby Hill were sold to the Eureka Consolidated Mining Co., of San Francisco, and an English concern, the Richmond Mining Co., bought adjoining property and, with characteristic British thoroughness, set about developing it. The Eureka Consolidated erected its furnaces at the lower end of Main St., and the Richmond works went up at the other. In 1875 the "Slim Princess" came puffing into town from Palisade, linking Eureka to the outside world, and prosperity came in with a whoop and a yell, bringing the nine graveyards with it. . . . As in Virginia City and elsewhere, nobody doubted the future—good times, they thought, would last forever; but it seems to be true that the more you take out of the ground the less you leave in.

PERSONALS

S. A. Worcester is at Ouray, Colorado.

J. Power Hutchins has been in the Altai region in Siberia.

George A. Denny, recently in Mexico, has gone to the Transvaal.

H. C. Enos has just returned from Central America and will spend several weeks in Utah.

Frank H. Probert left San Francisco Nov. 13 to visit the new gold camp at Oatman, Arizona.

Harold B. Gleeson is manager of the Mawchi mines in Burma, succeeding George Macfarlane.

W. M. Archibald has succeeded J. M. Turnbull as manager of the Consolidated Mining and Smelting Co. at Trail, in British Columbia.

J. D. Galloway, assistant provincial mineralogist, has been examining mining properties in the Big Bend and Slocan districts of British Columbia.

W. Hunnewell, of Wellesley, Mass., and C. W. Hanford, of New York, both connected with the Calumet & Hecla interests, visited the Michigan copper mines this week.

Taylor Allderdice, vice-president of the National Tube Co., Pittsburgh, has been appointed a member of the state board of education of Pennsylvania by Gov. Martin G. Brumbaugh.

Dr. Henry M. Payne was in Petrograd on Oct. 16, and expected to leave there early in November for London, by way of Sweden and Norway. He will sail for America in December.

H. F. Fay, president of the Mayflower and Old Colony properties near Houghton, Mich., accompanied by W. L. Frost, of Brookline, Mass., is in Michigan from Boston, visiting the properties.

R. T. McKeever, former manager of the Copper Range railway, but later connected with the firm of Logan & Bryan in Chicago, is now associated with Hornblower & Weeks in their Chicago office.

George B. Holderer, who recently returned from South America, has been made general manager of the Furlough Development Co., which is developing a copper property near Wickenburg, Arizona.

D. G. Kerr and McGilvary Shiras, of Pittsburgh, Penn., have been in the Lake Superior district for 10 days, looking over the mines of the Oliver Iron Mining Co., in company with the officials of that company.

R. L. Agassiz, president of the Calumet & Hecla and various subsidiaries, has returned to Boston, after an extended visit at the mines in Michigan. He was accompanied by Shaw McKane, of the eastern management.

Albert Sauveur, professor of metallurgy and metallography of Harvard University, presented an illustrated lecture on "The Industrial Importance of Metallography" at the Exchange Club, Boston, Nov. 10, before the NewEngland Foundrymen's Association.

John Saam, who, for the past 12 years has been assistant clerk at the Mohawk mine, resigned last week to become clerk and purchasing agent for the White Pine Extension, one of the Stanton properties recently operating in Ontonagon county, Michigan.

E. W. Maynard, who has been in charge of the Atlas Powder Co.'s plant at Senter, near Houghton, Mich., ever since its erection in 1910, has been promoted to the superintendency of the company's plant near San Francisco. He is succeeded by E. C. Eddy of New Jersey.

Frank M. Leland, manager of the Balaklala, after attending the mining congress and other engineering conventions at San Francisco and visiting the Panama-Pacific Exposition, is devoting some time to the affairs of the Balaklala at Coram, Calif. The mine is shipping ore to the Mammoth smeltery, and keeping up the demand for 250 to 300 tons a day.

John MacGinniss of Butte, George S. Deeks of New York, and Al Frank of the Ohio Copper Co., Bingham, Utah, have just visited their Delaware property at Vernon, Nev., in company with General Manager H. H Hunter of Lovelock. The result of the trip of inspection will be the institution of immediate development work to explore the Delaware veins at depth.

W. C. Ralston is preparing for a return trip to New York, where he has established an office at 25 Broad St. The purpose of the New York office is to attract Eastern men to the advantages of mining investments in California, Nevada and Alaska. Mr. Ralston has learned the futility of attracting California men to the possibilities of their home state in the industry of mining, and realizes that the development of the large mining properties has been the work of Eastern and European men.

OBITUARY

Thomas E. Frakes died at Sutter Creek, Calif., in October, at the age of 82 years. He crossed the plains shortly after the Marshall gold discovery at Coloma, and settled in Amador County, where he engaged in mining. In later years he gave up the mining business and carried on an extensive dairy ranch.

William H. Davis died at Alameda, Calif., on Nov. 7. He was born in Boston in 1831 and crossed the plains to California, settling in Eldorado County in 1852, where he engaged in mining. In 1859 he established the Union Lumber Co. in San Francisco. He was the last surviving charter member of Excelsior Lodge of Masons in San Francisco.

Professor Vivian B. Lewes died Oct. 16, at Mold, England, aed 64 years. He was for many years professor of chemistry at the Royal Naval College and was engaged in many important investigations, such as the chemistry of coal and its combustion, spontaneous combustion, oils, boiler corrosion, etc. He was also for a number of years chief gas examiner for the city of London. He was the author of several books on chemistry and combustion.

Henry Benjamin Smith died at Joliet, Ill., Nov. 7, aged 53 years. He had been in the Joliet Steel Works since he was a boy, entering the service of the old Joliet Steel Co.—later merged in the Illinois Steel Co.—in 1878 and gradually attaining a responsible position. He was one of the first to take up questions of safety work in the plants of the company and in 1893 was appointed supervisor of safety and labor, which position he had held ever since doing notable work in the cause of accident prevention.

Nicholas Treweek, of Salt Lake City, Utah, died in New York Nov. 8, as the result of an operation for throat trouble. He was born in Cornwall, England, and came to the United States when 20 years old. After a few years spent in Pennsylvania he settled in Utah and engaged in mining operations. He was identified with the opening and operation of many mines, notable among them being the Wabash at Park City, several properties in the Big Cottonwood district in Utah, the Lucky Boy in Idaho and several British Columbia mines. He was well known throughout Utah and was prominent as a Mason and a member of other orders. He leaves a widow, two sons and two daughters, all residents of Salt Lake.

Sir Andrew Noble died at Ardkinglas, Scotland, Oct. 22, aged 84 years. He was born in Greenock, was educated at Edinburgh and at Woolwich. He served for 15 years in the Royal Artillery and became an expert in ordnance and ammunition. After leaving the army, he became connected with the Elswick works at Newcastle, with which he continued for over 40 years, being for some time head of the great firm of Armstrong, Whitworth & Co. He was concerned in a number of important investigations, especially one on the products of combustion of powder, which he conducted with the late Sir Frederick Abel. He was a member of many learned societies and had received medals and other honors from a number of them.

INDUSTRIAL NEWS

The Anaconda Copper Mining Co. has ordered three additional 10-ft. by 48-in. Hardinge mills.

Nineteen parcels of land (an entire city block) have just been acquired by The Cleveland Galvanizing Works Co., Cleveland, Ohio, adjacent to its present location which is in the heart of the city.

The American Cyanamid Co. now has its general offices at No. 200 Fifth Avenue, New York. The Nashville and Buffalo offices were discontinued on Oct. 1. A southern office is maintained at 601 Walton Building, Atlanta, Ga.

The Salt Lake office of the Mine and Smelter Supply Co. has received orders for No. 64½ Marcy mills for the following companies: Silver King Coalition Mines Co., Park City, Utah, 2; Duquesne Mining Co., Duquesne, Ariz., 1; Red Banks Mining Co., H. C. Callahan, Bagby, Calif., 1.

This bulletin contains useful information about Byers pipe, such as its resistance to corrosion, fabricating and welding qualities, etc. Complete tables showing dimensions, areas and hydrostatic tests are given.

NEW PATENTS

United States patent specifications listed below may be obtained from "The Engineering and Mining Journal" at 25c each. British patents are supplied at 40c. each.

ANNEALING FURNACE. John E. White, Tarentum, Penn., assignor to West Penn Steel Co., Brackenridge, Penn. (U. S. No. 1,158,760; Nov. 2, 1915.)

CARS—Safety Device for Mining Cars. William Kowalski, Chicago, Ill. (U. S. No. 1,159,050; Nov. 2, 1915.)

CHARGING CAR. Frank D. Carney and Richard V. McKay, Steelton, Penn. (U. S. No. 1,158,982; Nov. 2, 1915.)

CONCENTRATOR HEAD MOTION. William H. Reagan, Jr., and John R. McMurray, Miami, Ariz. (U. S. No. 1,159,272; Nov. 2, 1915.)

CONVEYING, SORTING AND SCREENING SYSTEM. Gilbert Tollefson, Bagley, Minn. (U. S. No. 1,159,134; Nov. 2, 1915.)

CYANIDING—Treatment of Ores by the Cyanide Process. Hugh M. Leslie, Glasgow, Scotland. (U. S. No. 1,158,513; Nov. 2, 1915.)

DRILL—Rock-Drill Attachment. Harry H. Hughes, Poultney, Vt. (U. S. No. 1,159,034; Nov. 2, 1915.)

DRILL-SHARPENING APPARATUS. Arthur H. Skaer, Denver, Colo., assignor to The Denver Rock Drill Manufacturing Co., Denver, Colo. (U. S. No. 1,159,722; Nov. 9, 1915.)

DRILLS—Improvements in Power-Driven Rock Drills. M. Kellow, Penrhyndeudraeth, N. Wales. (Brit. No. 13,067 of 1914.)

ELECTRIC FURNACE. Percy A. Boeck, Worcester, Mass., assignor to Norton Co., Worcester, Mass. (U. S. No. 1,158,971; and 1,158,972; Nov. 2, 1915.)

FLOTATION—Separation of Minerals by Flotation. Lewis G. Rowand, Brooklyn, N. Y., assignor to New Jersey Zinc Co., New York, N. Y. (U. S. No. 1,159,718; Nov. 9, 1915.)

FULLER'S EARTH—Earth-Treating Process and Product. Michael J. Welsh, Philadelphia, Penn., assignor to The Atlantic Refining Co., Philadelphia, Penn. (U. S. No. 1,159,450; Nov. 9, 1915.)

FURNACE and Allied Structure. Utley Wedge, Ardmore, Penn. (U. S. No. 1,159,141; Nov. 2, 1915.)

FURNACE-DOOR LINING—Edward S. Cline and Edward C. Meier, Phoenixville, Penn. (U. S. No. 1,159,898; Nov. 9, 1915.)

FURNACE LINING. Albert P. Meyer, Aspinwall, Penn., assignor to Allen S. Davison Company, Pittsburgh, Penn. (U. S. No. 1,160,085; Nov. 9, 1915.)

JIG. Walter S. Tower and Peter D. Camphuis, Wallace, Idaho. (U. S. No. 1,159,295; Nov. 2, 1915.)

LEAD ALLOYS Containing a Plurality of the Metals of the Alkaline Earths. Francis C. Frary, Minneapolis, and Sterling N. Temple, St. Paul, Minn.; said Temple assignor of one-sixth of the whole right to said Frary. (U. S. No. 1,158,672; Nov. 2, 1915.)

METAL-MELTING FURNACE. Oro J. Warman, Cincinnati, Ohio, assignor, by mesne assignments, to Buckeye Products Co., Cincinnati, Ohio. (U. S. No. 1,158,873; Nov. 2, 1915.)

MINE-CAR LUBRICATOR. Charles Goyn, Gorham, Colo. (U. S. No. 1,160,067; Nov. 9, 1915.)

NITROGEN COMPOUNDS—Process of Producing Nitrogen Compounds of Aluminum and Alkali or Alkaline-Earth Metals. Dmitry Alexandrowitch Peniakoff, Brussels, Belgium. (U. S. No. 1,159,989; Nov. 9, 1915.)

POTASH—Process of Recovering Potash from Potassium-Iron Silicates. Harry P. Bassett, Catonsville, Md., assignor to The Spar Chemical Co., Baltimore, Md. (U. S. No. 1,159,464; Nov. 9, 1915.)

REFRACTORY MATERIAL — Highly Refractory Material and Process for Making It. August Pfaff, Freiberg, Germany. (U. S. No. 1,159,264; Nov. 2, 1915.)

SCREEN—Shaking Screen. Paul M. Kuehn, Baltimore, Md., assignor to Bartlett Hayward Co., Baltimore, Md. (U. S. No. 1,159,317; Nov. 2, 1915.)

SCREENING APPARATUS. Paul M. Kuehn, Baltimore, Md., assignor to Bartlett Hayward Co., Baltimore, Md. (U. S. No. 1,159,318; Nov. 2, 1915.)

SEPARATION—An Improvement in the Magnetic Separation of Ores. Graf Botho Schwerin, Frankfort-on-the-Main, Germany. (Brit. No. 19,313 of 1914.)

SULPHATING—Method of Sulphating Materials. Henry B. Hovland, Duluth, and George B. Frankforter, Minneapolis, Minn.; said Frankforter assignor to said Hovland. (U. S. No. 1,159,032 and 33; Nov. 2, 1915.)

SULPHIDE ORES—Imported Method for the Recovery of Cuprous Sulphide from Ores and the Like. Metals Research Co., New York City. (Brit. No. 143 of 1915.)

SULPHIDIZING—Method of Sulphidizing Metals. Henry B. Hovland, Duluth, Minn. (U. S. No. 1,159,942; Nov. 9, 1915.)

TRANSIT. Adolph Lietz, San Rafael, Calif. (U. S. No. 1,159,510; Nov. 9, 1915.)

ZINC—Device for Removing Residue from Retorts. Nicholas L. Heinz, La Salle, Ill. (U. S. No. 1,160,077; Nov. 9, 1915.)

ZINC—Method for the Treatment of Zinc Ore or Zinc-Bearing Material. Sewall Truax, Canon City, Colo., assignor to Granadena Mining Co. (U. S. No. 1,155,625; Oct. 5, 1915.)

ZIRCONIUM OXIDE—Method of Producing White Zirconium Oxide Free of Iron. Paul Askenasy, Karlsruhe, Germany, assignor to Chemisch Metallurgische Industrie-gesellschaft mit beschränkter Haftung, Berlin, Germany. (U. S. No. 1,158,769; Nov. 2, 1915.)

Editorial Correspondence

SAN FRANCISCO—Nov. 10

California Metal Producers' Association—At the recent annual meeting at San Francisco the following officers were elected: President, Albert Burch; vice-presidents, G. W. Metcalfe, E. C. Hutchinson; secretary-treasurer, R. I. Kerr; executive committee, G. W. Starr, C. E. Knox, N. Cleaveland, S. W. Mudd.

The Comstock Mines are shaking off the ghostly raiment with which a recent magazine story invested the town of Virginia City. In the last half of October and the first quarter of November, Union Consolidated and Sierra Nevada explored high-grade orebodies on the 2,500 level. The ore in the Comstock north-side mines has been running at from $8 to $12 per ton, with an occasional shoot of higher grade. Recent disclosures have increased the value to a probable average of $40 per ton. As early as the week ended Oct. 16, Union Consolidated saved 83 cars average $49 per ton and 35 cars which averaged $63 per ton. In the same week Sierra Nevada ran into ore worth $11 per ton and in the week ended Oct. 23 the face of the north drift of the 2,500-ft. level showed ore running as high as $130 per ton; with an encouraging outlook for a large high-grade orebody in this neighborhood. In the same week the north end of No. 1 stope of the Union 2,500 level was in ore averaging $79 per ton. At another point samples showed $89 per ton. The ore saved from this stope averaged $26.90 per ton. Six feet of $50 ore was found in No. 3 stope of the Union in the week ended Oct. 30, and in the same week Sierra Nevada extended the north drift 10 ft. into ore averaging $32.34 per ton, while the face was in $85 rock. In the first week in November, Sierra Nevada saved ore averaging $33 per ton and Union Consolidated found various grades running $13.72, $24.60 and $45.16. Herman Zadig, of San Francisco, one of the directors, returning from Virginia City after a visit to the north-end mines, stated that the recent development in the Sierra Nevada proved the contention of himself and other directors that the Comstock was not dead. He considered this disclosure of high-grade ore of great importance, because it was in the Sierra Nevada in 1878 that the bonanza people thought they had found another orebody similar to the one that was then being worked in Consolidated Virginia. Mr. Zadig and Mr. Slosson and Mr. Ralston have been sanguine that large orebodies would be found in the 2,500 and 2,700 levels. In their opinion the work now being done on 2,500 level proves to a certainty that there is a chance of extensive orebodies at this point. It seems reasonable that if the early-day management had believed in 1878 that ore persisted in large bodies to the 2,700 level, they would have mined it because silver was then worth $1.29. However; without assuming to disagree with these opinions it may be taken as indisputable that Fair and Flood and Mackay did, and left undone, many things which were incomprehensible to mining men of that day. The past performances of the past-masters of Comstock mining are not of such great interest to the present-day management as the fact that the Comstock ghost has begun to walk again.

DENVER—Nov. 11

The Phenomenal Demand for Tungsten has created conditions in Boulder County that, for a brief time, threatened the organization of a miners' union. The idea, it is believed, was thwarted at its inception by prompt action of the leading mine operators in establishing a new and uniform wage scale for miners at 45c. per hour. The regular wage has been $3 for eight hours. The "boom" continues unabated at Nederland.

The American Metals Producing Co., controlled by E. S. Moulton and G. Whitney Adams, is attracting attention by its activities at Black Hawk. Mr. Moulton has, for years, owned the Rocky Mountain concentrator, a fair-sized crushing and jigging plant formerly operating on custom ores. This mill occupies the exact site of the first smeltery in the state—the Hill furnace, materials for the construction of which were hauled by ox-teams from St. Joseph, Mo. While this mill has lain idle for several years, these men have been experimenting along hydro-metallurgical lines and they believe they possess a wet process for recovering the precious and the several base metals in Gilpin county ores. The secret process is known to include roasting and lixiviation followed by selective precipitation. Two carloads of machinery have been delivered to be erected on foundations now being laid in the remodeled building.

BUTTE—Nov. 10

In the Districts Tributary to Helena, former Senator W. A. Clark has bought Monte Cristo mine, situated 2 mi. north of Rimini, and work will be begun immediately. Purchase price said to be $100,000. Syndicate which recently acquired "Head" mine on Scratch Gravel has been formally incorporated as Scratch Gravel Gold Mining Co. for $1,000,000. W. E. Cullen, of Spokane, Wash., is president of company. Last month was first month ore was hoisted and profits aggregated $24,000. The Monarch mine near Elliston, has been leased and bonded to a group of Helena mining men. Development work will be started at once. Property lies on north slope of Bison Mountain, 9 mi. south of Elliston, and 6 mi. south of Rimini. Property is developed by shaft and tunnel, where body of commercial galena ore has been opened up. Several carloads of high-grade ore have been shipped and thousands of tons of low-grade ore are on dump awaiting treatment. Property is one of most promising in district. Helena Mining Bureau has leased and bonded Little Wonder mine and stamp mill, at head of Nelson gulch, and work will be commenced as soon as necessary improvements are made.

SALT LAKE CITY—Nov. 11

The Ore Production of Bingham at present is in the neighborhood of 945,000 tons of ore per month. The Utah Copper is producing 27,500 tons of ore daily, and the Utah Consolidated, United States Smelting, Bingham-New Haven, Utah Apex, Bingham Mines, Utah Metal and Tunnel, 2,000 tons more, which with 2,000 tons being mined and milled at the Ohio Copper makes a total daily output of approximately 31,500 tons, or 945,000 a month.

The Strike at the Silver King Coalition mine in Park City ended Nov. 9, when a miners' meeting was held, and it was voted to return to work. Notices had been posted by the company to the effect that the miners would be taken back in their old standing, if they signed the compensation agreement and returned to work before 6 o'clock, Nov. 10. Exception was made of some of the shift bosses who had struck, and a certain number of men deemed agitators. Of the 210 former employees, who applied for work on Nov. 9, 149 were signed up. Some work was done on the night shift Nov. 9, and a full shift was worked Nov. 10. Things at the mine will soon be in normal running order. Up to 6 o'clock on Nov. 10, 230 men, out of the 370 who walked out, had signed the compensation and insurance contracts over which they struck two weeks ago. The strike has been characterized by freedom from violence or other demonstration, and the men have conducted themselves in an orderly manner throughout the time they were on strike.

In the New Zinc Camp, Lakeview mining district on Promontory Point, Box Elder County, there are now eighteen incorporated companies, and about 150 men are employed. The Lakeview Mining Co. declared another dividend of 2¼c. a share Nov. 6. This calls for the distribution of $11,250. In October a similar amount was paid, making $22,500 in two months. In June, July and August seven mills a share was distributed each month. Altogether approximately 7c. a share has been paid on the 500,000 shares, making total dividends of about $35,000. To date shipments have amounted to 67 cars of zinc ore containing 3,149 tons, which averaged 32.75% zinc. The prices received varied from $27 to $55 a ton. This ore at an average price of $40 per ton brought approximately $124,960. In addition to the above, five cars have been shipped by lessees. Three thousand feet of tunnel work has been done; a new compressor was installed and placed in operation Nov. 6, and a new lower tunnel is being started to prove the ore at greater depth. It is reported that an option has been taken on this company's property by the A. S. & R., which is doing development.

FARGO, N. D.—Nov. 13

Dakota Lignite for heating will hereafter be used by all state institutions of North Dakota. In most cases however it is necessary to mix with some bituminous coal, owing to the high moisture content of lignite.

OURAY, COLO.—Nov. 10

The Wanakah Mining Co., operating claims adjoining the American Nettie ground, north of Ouray, and in control of the Ouray smelting works, is planning to conduct extensive explorations and to expand the smelting operations so as to treat custom ore. The control of the company has recently been changed and G. W. Barnhart, of Ouray, formerly manager of the Mountain Top mine, at Telluride, has succeeded John T. Roberts, Jr., in the management of the property. George H. Beebe, of Syracuse, is the new president. The mine is connected with the mill by an aërial cable and the ore is hauled from the mill to the smeltery 2 mi. by railroad. The ore is mostly heavy iron sulphide with from 2 to 8% copper and some precious metals. Some of the ore is amenable to milling but owing to the large loss of copper in the mill, practically all of the output now goes to the smeltery. The smeltery, which was improved and enlarged last summer has a capacity of 250 tons a day, but this has been reduced to 150 tons by a fire-brick partition in the furnace chamber. Semi-pyritic smelting is practiced with a consumption of about 10% coke. A two-unit Greenwalt sintering equipment is installed. The matte is shipped to Garfield, Utah. The company has heretofore largely depended upon its own mine for smelting ore but is now planning to treat custom ore, particularly siliceous ores, a policy which has already had its effect of stimulating operations in the district. The Wanakah mine in the last four years has produced nearly a million dollars gross.

The American Nettie Property now belongs to the American Gold Mining Co., of St. Louis, Mo., W. C. Wisberg president. The company drove a tunnel to the Wanakah ore horizon and several other operations are under way to explore for deposits of the Wanakah type in the sedimentary cliffs north and east of Ouray. The Two Kids property has opened up an orebody and is building a small mill. This operation is financed at Delta, Colorado. On Black Silver Mountain to the north of the American Nettie, limited operations are under way on the Black Girl, the Scotsman and the Cutler Creek properties.

The Results of the Development at Wanakah have aroused interest in the possibilities of the sedimentary areas in the vicinity of Ouray, which occur extensively north and west of the town and which are cut by numerous dikes. The important mineralization so far has been found on the east side of the cañon only and its extent is still to be determined.

In Poughkeepsie Gulch, Uncompagre Cañon, the Old Lout mine, now owned by the Onetal company, 10 Wall St., New York, is being equipped with an electric compressor and drills for extensive development. This vein has been opened on the surface for about 600 ft. in depth and has a record of about $800,000 production of rich bismuth-silver ore. The tunnel cuts the vein at about 1,000 ft. in depth and a drift on the vein has opened three oreshoots, showing sulphide ore, with copper, lead, zinc and silver. The company has a lease on the Mickey Breene mill and is to introduce flotation. It is expected that some shipping ore will be extracted this winter. Frank M. Jackson is in charge. This property was last worked by an English company in the early nineties.

The Maid of the Mist adjoins the Old Lout on the north and will probably be developed from the Lout tunnel. The Poughkeepsie mine, at the head of the Gulch, has suspended developments but will resume in the spring. The Benock, on the north extension of the Lout is being operated on a lease by John T. Roberts, Jr.

No Work Has Been Done during the past season on the San Juan Chief, the Huff or the North Star properties, all of which lie east of the Lout. The Ben Butler is under option to W. M. Waybright and some work has been done on it. The ore in the Ben Butler is zinc with gold. W. J. Rattles, of Cleveland, Ohio, is in charge of work on the Vermilion mine, about half a mile south of the Ben Butler. The Columbus tunnel, in this vicinity, is being extended to cut the Columbus vein. On Red Mountain the National Belle is under lease to Messrs Roberts, Wood and Forest, of Ouray, and is shipping, regularly, high-grade copper ore. When the mine was opened recently it was found that the rails, tools and nails of the old equipment were entirely replaced by copper.

WALLACE, IDAHO—Nov. 10

American Institute of Mining Engineers—The fifth annual meeting of the Columbia Section will be held at Wallace, Idaho, Nov. 19-20. A special train leaving Spokane at 8:30 a.m. will arrive in Wallace at 12:50 p.m. At 3:00 a technical session will be held in the public library, at which D. W. Buckby will present a paper on "Progress in Ore Dressing" and J. E. Chapman one on "Mine Accounting." At the evening session W. E. Henry will discuss "Zinc Smelting and Smelter Rates." The following day will be given over to a trip to the Interstate-Callahan, Tamarack and Success mines on Ninemile; a business session and banquet will be held in the evening. A special invitation has been extended to members of the Montana section of the Institute.

PHILADELPHIA—Nov. 15

Pennsylvania State College—The new mining building of the School of Mines was dedicated on Nov. 5. Dr. H. M. Chance, of Philadelphia, the speaker of the day, took as his subject "The Conservation of Mineral Resources." There was a large gathering of people, among whom were many prominent mining men from both the bituminous and anthracite fields The museum of the school, one of the best in the United States, is being installed in the new quarters, which together with the added facilities for classroom and laboratory work, will contribute materially to the increased usefulness of the school. The School of Mines was established in 1884 and has graduated a large number of men now prominent in mining in Pennsylvania as well as in many other states.

IRONWOOD, MICH.—Nov. 13

Shipments from the Gogebic Range for 1915 will exceed 5,000,000 tons. To Oct. 25, the Chicago & Northwestern Ry. Co. had hauled 3,600,000 tons of Gogebic ore to the Ashland docks. The most the company has ever handled in a single year was 3,760,000. The Soo line will take out about 1,000,000 tons this year.

HOUGHTON, MICH.—Nov. 13

A Million a Month in Wages Was the Slogan when the copper country of Michigan hoped, some day, to reach total monthly pay roll of a million. At the present time that slogan is out of date. A million and a half a month is more nearly correct. Each Saturday pay day the mining corporations distribute to employees at least $700,000. This is for half a month's work. One mining corporation alone pays out over $230,000 in cash.

BRAINERD, MINN.—Nov. 11

Indian Commissioner Sells ordered closed on Nov. 1 all saloons in Chisholm, Hibbing, Taconite and several smaller Mesabi Range towns. Entire Cuyuna Range has been "dry" for some time, and the commissioner's action now makes large part of Mesabi Range dry as a desert. Mine operators in general favor the drys.

TWO HARBORS, MINN.—Nov. 10

Duluth & Iron Range Ry., announces according to W. A. Clark, chief engineer, that it will expend $1,635,000 for dockage facilities at Two Harbors. A steel and concrete dock, costing $1,500,000, will be built, and Dock No. 6 will be remodeled. The new, or No. 2 Dock, will be 80 ft. high, with 228 pockets.

At Two Harbors Dock, 10,098 carloads came from the Biwabik District in October, being a nominal decrease from September. The Biwabik and Bangor mines are the leading shippers, with 1,286 and 1,416 cars respectively to their credit. The total ore tonnage for October via Duluth-Superior and Two Harbors docks was 1,800,000 tons in excess of October, 1914, all roads participating in the increase except the Great Northern which had a decrease of 150,000 tons. At Ashland, Wis., all iron ore shipping records have been broken, and indications point to still greater figures for next season. To Nov. 1 the C. & N. W., and Soo Line docks had a combined tonnage of 4,754,397 with several weeks yet to operate, while the best previous season (1912) totaled but 4,797,101 tons.

VICTORIA, B. C.—Nov. 8

The Leona, carrying a heavy cargo of ore from the Britannia mines on Howe Sound to the Tacoma smeltery, turned turtle and foundered due to the shifting of her cargo during a heavy gale when nearing Active Pass on the night of Oct. 31. Seven out of the crew of 14 were drowned.

TORONTO—Nov. 13

The First Run of Manganese Steel ever manufactured in Canada was turned out on Nov. 6 by the Wabi Iron Works, of New Liskeard in Northern Ontario. It is produced by electric process in a furnace of the Heroult type having a capacity of 5 tons per day.

Part of the famous "silver sidewalk" that contributed to so much of the excitement in the early days of Cobalt has been purchased by the Department of Mines and is being removed. The Department does not wish to allow such a remarkable specimen to be lost, and as there is little probability of such a showing ever again being discovered, it will be kept for the museum.

The Mining News

ALASKA

ALASKA GOLD (Juneau)—In October treated 154,500 tons of ore, compared with 132,000 tons in September. Total cost per ton is now under 60c., and tailings are running under 19c. Plant is regularly treating 6,000 tons per day, which is approximate limit of present power capacity at Salmon Creek. New power plant at Annex Creek should be in commission in December, when operations will be brought up to 10,000 tons capacity.

ARIZONA

Gila County

KEYSTONE COPPER (Miami)—At special meeting of stockholdders it was voted to dissolve company and distribute assets to stockholders. Meeeting of directors to be held immediately to arrange distributon.

ARIZONA ASBESTOS ASSOCIATION (Globe)—Has opened up a large deposit of chrysotile asbestos of the finest quality at Ash Creek Cañon. Output is sold some time in advance and is being used by most exacting manufacturers of asbestos textiles.

INSPIRATION CONSOLIDATED (Miami)—Is operating 9 out of 18 sections of mill and is handling 7,000 tons of ore daily; extraction of 82% being secured on average of all ore handled; recovery on sulphide ore alone is about 93%. During October produced about 4,000,000 lb. of copper. November output expected to be greater.

Greenlee County

ARIZONA COPPER (Clifton)—Company's Clifton concentrators Nos. 2 and 3, instead of No. 4 as reported, together with 300 ft. of big ore bins and conveyor belt leading from the mill to the leaching plant, burned Nov. 5. Fire started about 8 o'clock and lasted greater part of night, and but for work of fire fighters, company's store, leaching plant and other property would have been destroyed. Deputies and pickets state that conflagration started near top of old mill, and Sheriff Cash, in whose care property has been since managers left district, claims it was due to defective wiring. Men who are familiar with plant, however, are positive that fire could not have been caused by loose wires in the locality where it originated. Property that burned was not being used when strike was called, Sept. 11, but was being extensively remodeled, and new and modern machinery was being installed. The loss is estimated at $100,000 to $150,000. Destruction of property would not preclude an early resumption of work should managers and strikers come to an agreement.

Mohave County

LEVIATHAN MINES (Oatman)—Recently encountered ledge of ore in its mines averaging more than 50% copper.

UNITED STATES SMELTING (Kingman)—Has taken option on Antelope and Democrat claims, situated in Wallapai Mountains, from their owners, W. H. Murphy and W. F. Dunlap.

ARIZONA TELLURIUM CO. (Kingman)—Is preparing to install hoist, compressor and other machinery at its mines in Wallapai Mountains, 16 miles east of Kingman. The ore runs high in gold and silver.

COLORADO RIVER PLACERS (Oatman)—D. P. Mitchell and associates are negotiating with syndicate of Eastern men for sale of about 2,000 acres of placer ground, situated along lower course of the Colorado River. Mineral bearing bars are 35 to 45 ft. deep.

Pinal County

MAGMA COPPER (Superior)—For quarter ended Sept. 30 company produced 1,973,960 lb. copper, at an average cost of 5.72c. per lb., compared with 1,302,199 lb. at 6.19c. per lb. for preceding quarter. Operating profit for third quarter was $238,490, compared with $186,057 for preceding quarter.

Yavapai County

TELSORI MINING (Cherry Creek)—Company is erecting new stamp mill at its Nelson mine. Has large amount of ore blocked out.

DEVELOPMENT CO. OF AMERICA (Congress)—Is reported to be negotiating for sale of its Congress gold mine, including old tailings dump, which contains about 1,200,000 tons of ore, valued at $2 per ton.

PORTLAND-ARIZONA (Copper Basin)—O. W. Bickenstaff and associates have sold their group of 28 Portland-Arizona copper claims to D. M. Louey, of St. Louis, Mo., and associates. The new owners will conduct extensive development operations.

CALIFORNIA

Amador County

EAST EUREKA (Sutter Creek)—Cleaning out and repairing north shaft, which was caved about 20 years ago. Recent development has been through south shaft, which proved that greater possibilities of developing pay orebodies lie to north.

Calaveras County

UTICA (Angels Camp)—Repairs in progress at Stickle mill and Cross shaft, preparatory to resuming operation when water supply is sufficient.

CALAVERAS COPPER (Copperopolis)—Forty men reported to have been laid off because of lack of bin capacity for ore extracted, which is in excess of mill capacity. Reported that additional concentrating installation is contemplated.

Eldorado County

WAGNER (Lotus)—High-grade ore reported disclosed in 37-ft. drift from 54-ft. shaft. New machinery will be installed before proceeding with further development. Ore contains large percentage of copper and some gold.

COX & MASSA (Placerville)—Work started in 600-ft. tunnel. Reported that rich gravel has been disclosed. Large body of deep gravel opened on Coffin & Reed property adjoining.

STILLWAGON (Placerville)—Los Angeles men have leased this property at forks of Cosumnes River, 2 mi. south of Caldo R.R. Present operators are extending 800-ft. tunnel about 100 ft. in belief that oreshoot will be tapped at vertical depth of 500 ft. Mine is equipped with stamp mill and electric generating plant, both operated by water power.

Inyo County

WILSHIRE-BISHOP CREEK (Bishop)—Arthur Joslin was killed Oct. 22 by falling of an ore car into shaft, car striking cage in which Joslin and three other men had descended.

CERRO GORDO (Keeler)—Contract reported signed by F. J. Hambley and A. L. Dornberger on behalf of company and Southern Sierras Power Co., for electric current for mine for lighting, drilling, hoisting and all other operations.

Kern County

HOPE (Randsburg)—Philadelphia men reported to be negotiating for control. Deepening of 250-ft. shaft to 500 ft. contemplated. Large shoot of ore disclosed at 250 ft. Recent shipment of ore averaging $80 per ton.

Merced County

SAN JOAQUIN LIGHT AND POWER (Merced Falls)—Work begun on construction of new $65,000 plant for generating electric power.

Modoc County

SEITZ (Cedarville)—Copper claims on Neasham Mountain have been bonded to T. G. Elgie. Development work has disclosed good copper-bearing ore in 5-ft. ledge.

Nevada County

SPENCEVILLE MINERAL (Spenceville)—All buildings and surface plant destroyed by fire night of Oct. 30. Suspected incendiary origin. Copper revival had induced preparations for operating on much more extensive scale.

BLACK BEAR (Rough and Ready)—Directors have retained William Buchholz as managing director; William Gans is superintendent. Company was recently reorganized and sufficiently financed to deepen shaft and install machinery for development work.

MOHAWK (Graniteville)—Antimony ore reported to be found in sufficient quantity and quality to justify reopening of this mine on Moores Flat, owned by William McLean of Graniteville and Charles Scheunert of Sacramento. Old tunnel is being cleaned out and placed in condition, and driving on the vein will be resumed.

WILLOW VALLEY (Nevada City)—New electric pump with capacity of 500 gal. per min. is being installed. This will permit development to depth of 1,200 ft. Montana shaft now down to 830 ft. Both properties have records as producers and it is believed that they will again be put in producing class.

Placer County

GREEN EMIGRANT (Forest Hill)—R. A. Nicol has bonded this mine on Bald Hill to E. W. Drumond and Joe Delmue. Reopening and development will begin immediately.

Sierra County

ANDY FITZ (Alleghany)—Permit issued by Commissioner of Corporations to sell 75,000 shares stock at 25c. to finance exploration and development of quartz ledge.

KLONDIKE (Sierra City)—Machinery and winter supplies being taken in for continuing tunnel to tap gravel channel, expected within 100 ft. more. W. W. Tiner in charge.

Siskiyou County

MANGANESE claims have been located near Black Bear mine in Salmon River district. Ore said to contain high percentage of manganese. Surface crosscut has been run 144 ft. Ledge is almost vertical; walls are porphyry and diorite. Reported that New York men have taken a bond and will develop property.

SISKIYOU MINING (Etna)—The 15-mi. flume is being lengthened 1½ mi. to cover Muck-a-Muck flats which embrace about 400 acres of gravel. Property is owned by Dr. Harback and Mr. Gardner of New York. Mr. Payne is superintendent.

Trinity County

TRINITY ASBESTOS (Cinnabar)—Closed down for winter. Work will be resumed as soon as weather will permit in the spring.

BONANZA KING (Trinity Center)—Has abandoned old 3-mi. tramway, and has erected bunk houses, cook house and mill at mine, and will operate now during winter as well as summer.

CRAIG (Dedrick)—R. W. Hamilton, of Weaverville, and H. C. Stofer, of Dedrick, have taken a five-year lease on this property owned by Globe Consolidated Mining Co. Development work will be carried on throughout winter.

GLOBE CONSOLIDATED LEASE (Dedrick)—Began operating the Globe Consolidated Co.'s mill and properties at Dedrick, Oct. 1. About 40 men are at work developing orebodies on Bailey and also on two levels of Globe. Archie Burnett is new manager.

BELLI (Coffee Creek)—Property shut down for the winter after successful and steady run since July 4. Ore put through mill averaged $30 per ton. New wagon bridge is being constructed across Trinity River while water is low.

BONANZA KING (Weaverville)—Large orebody reported in lower tunnel driven 1,500 ft. into hill. Milling plant being moved to mouth of tunnel which will save transportation of ore over a mile of tramway. Tramway is in heavy snow belt and is difficult to keep in order.

Tuolumne County

REPUBLICAN (Sonora)—Purchase bond covering five mining claims and 20-stamp mill delivered to F. W. Page, manager Royal Consolidated mine at Hodson, Calaveras County. Mr. Page represented Eastern men in this deal. Shaft is 700 ft. deep. Price said to be $65,000.

COLORADO

Gilpin County

EAST NOTAWAY (Russell Gulch)—In the "Journal" of Oct. 23 was published an item in this column stating that the mine after being closed for a year by litigation, had been finally secured by opposing litigant, Colomo Mining Co., and was to be reopened. We have various communications from parties to the two sides of the litigation relative to the item and to each other. We hold our honorable correspondents in equal esteem, and considering our distance from the clouded issue, we are disinclined to judge the evidence.

San Miguel County

TOMBOY (Telluride)—At recent meeting in London it was announced that Sidney White Cloud group of claims, situated to north of Bushwhacker claim, and carrying extension of Montana vein, has been acquired for consideration of $75,000, to be paid in cash instalments before June 15, 1916. During October mill ran 29 days; crushed 13,000 tons of ore. Bullion and concentrates shipped totaled $88,400; expenses, $60,600; operating profit, $27,800.

IDAHO

Shoshone County

INTERSTATE-CALLAHAN (Wallace)—Shipments during October were heaviest in history of mine, totaling 6,500 tons of crude ore and concentrate.

AMERICAN-COMMANDER (Wallace)—This company is building blacksmith shop at tunnel portal and otherwise preparing for winter work. Has 400 ft. of crosscut yet to drive to reach vein.

ALAMEDA (Wallace)—Is suing Success, alleging illegal extraction of ore to value of $30,000 from its ground; Success admits extraction of ore but claims title to ore under apex law. Rumored that properties will be consolidated and action dismissed.

CASTLE ROCK (Wallace)—Idaho-Nevada Exploration Co., has resumed work on Castle Rock situated on Placer Creek. Operations delayed by lack of water for power. Crosscut from 200-ft. level of shaft has penetrated vein 20 ft.; 12 ft. of ore assaying 4 to 5% copper reported; small stringer assaying 3% zinc and 3% lead on footwall.

BERNICE (Kellogg)—Capital stock of this company increased from 200,000 to 1,500,000; 250,000 shares of new stock to be transferred to Wardner Mining and Milling Co., in exchange for its holdings. Bernice company owns 8 claims east of Caledonia, on which two veins have been located; will drive crosscut to cut veins at intersection.

MARSH (Burke)—Reported strike of 18 in. of shipping ore in crosscut from 900 level. As soon as oreshoot is explored sufficiently to prove persistence, sinking will be continued to 1,200 level. Large pump ordered; first summer will be installed temporarily at 900 level but will be removed later to 1,200. Remodeling of mill on Ninemile completed, increasing capacity from 150 to 225 tons daily.

GALENA GROUP (Wallace)—Coeur d'Alene M. & S. Co., plans to develop Galena group, lying west of Success on Ninemile. Two tunnels previously run and winze sunk 60 ft. from upper; good showing of carbonate ore, but work was suspended on account of water. Crosscut tunnel driven 900 ft. tapped vein at depth of 500 ft.; 400 ft. of driving on vein necessary to get under ore in shaft.

PORTLAND (Sunset)—D. L. McGrath, manager for the Ray-Jefferson company, has taken option on Portland claims on Sunset Peak, situated between Sunset Group, owned by W. A. Clark, of Montana, and Tuscumbia group. Claims have been idle since death of Georg B. Markle, organizer of Portland company. Two tunnels each about 500 ft. long have good showing but maximum depth obtained was only 100 ft. Owing to elevation of mine and heavy snowfall development will not be started till spring.

MICHIGAN

Copper

HOUGHTON (Houghton)—Sinking continues in good commercial rock.

NEW ARCADIAN (Houghton)—Third test of copper rock satisfactory, 1,500 tons being handled.

WOLVERINE (Kearsarge)—Rock running close to 18 lbs. to ton. Rock keeps two stamp heads running to capacity.

BALTIC (Painesdale)—Richest copper-bearing ground yet located in this mine is now proven to extend from 14th to 22nd level. Increase in rock tonnage expected soon.

COPPER RANGE CONS. (Painesville)—Announcement made of 10% bonus for November and December for 3,000 or more men working at mines and mills of Copper Range company.

SOUTH LAKE (Houghton)—New steel shaft-rock house will be built within four months. Foundations now being laid. Both 3 and 4 lodes in commercial ore. Expected that 10,000 shares new stock will be subscribed by present share owners.

BALTIC (Painesdale)—Transmission line, from Redridge mill plant is under construction to mine over right of way of Atlantic railway, to utilize excess turbine power at Baltic mine, a subsidiary of Copper Range. W. A. Rankin, chief electrical engineer of Copper Range is in charge.

CHEROKEE (Houghton)—Operations suspended for winter. Work economically conducted under direction of W. A. Hodgson and results in three exploration pits showed good prospects. Small exploration shafts will be put down in most promising pits next summer.

VICTORIA (Victoria)—Conditions continue to improve. It will be several months before new hoist is in running order and new shaft ready for work. That will mean larger tonnage and closer selection, so that 13 lbs. per ton can be maintained. This can be operated profitably by Victoria even if output is sold on 13c. basis, because of low power costs.

WHITE PINE (Ontonagan)—Railway connection now is established and within week regular train service will be in operation. St. Paul end of line was finished week ago and connection made with portion built by Smith, Byers & Sparks on contract for Calumet & Hecla. This will mean enormous savings for White Pine. At present 90 men are employed cutting wood for fuel for the boilers. There is large accumulation of mineral on hand waiting to go to smelter at Hubbell.

Iron

DOBER (Iron River)—Oliver Iron Mining Co. is to sink another shaft here. Work will be started soon after Jan. 1.

CLEVELAND-CLIFFS IRON (Ishpeming)—Has only about 45,000 tons more to ship this season. L. S. & I. road expects to be through handling iron ore by Nov. 20.

BUCKEYE (Commonwealth)—This property has been abandoned by Oglebay-Norton & Co. Sulphur content of ore is too high. Is one of oldest mines on Menominee Range.

OLIVER IRON MINING (Ironwood)—Night shifts have been added at mines that have not been working with two forces. Pabst has had two crews for some time. About 400 more men will be given employment.

MASS (Negaunee)—A Halby loading machine is being tried out underground. It is working successfully but has not been in operation long enough to give data. The Lake Shore Engine Works is building 10 of the machines. Most of them will be shipped West. The Copper Queen Mining Co. has ordered one shipped to Bisbee, Ariz.

MINNESOTA

Duluth

MINNESOTA IRON DEVELOPMENT (Duluth)—Has obtained fee to 8,697 acres of mineral lands in St. Louis, Crow Wing and Aitkin Counties. Options are held on 591 acres additional. Properties are located on Mesabi, Vermilion and Cuyuna Ranges. Exploring is to be started immediately. E. J. W. Donahue, formerly of Cuyuna-Mille Lacs and Cuyuna-Duluth companies, is one of directors.

Cuyuna Range

CUYUNA-MILLE LACS (Ironton)—Shipping 10 cars daily of its manganiferous product.

Mesabi Range

TIOGA (Chisholm)—Shaft now down 103 ft., and working in wet ground.

DEAN (Buhl)—All shipping has ceased and mine was shut down Nov. 6.

MYERS (Chisholm)—All ore in stock is to be shipped this fall. This will be last of Oliver piles to be moved.

TIOGA (Chisholm)—Excavating is completed in engine house for engine bed. Work on new change house is progressing satisfactorily.

HAWKINS (Nashwauk)—Mine was closed down Nov. 4. No more ore will be shipped this season. Averaged about 70 cars a day during last two months.

EUCLID (Chisholm)—M. A. Hanna Co. is to ship ore in stock here. Mine is near lake and could not be kept open. Water kept coming in until workings flooded.

ALEXANDRIA (Chisholm)—All of dwelling houses for men have been completed. Drifting is going on from bottom of main shaft. Timber shaft is going down steadily.

OLIVER IRON MINING (Eveleth)—Stated that Fayal and Genoa mines will be operated all winter. About 650 men will be kept employed at two properties. Company has shipped 1,100,000 tons from Eveleth district this season.

Vermilion Range

CHANDLER (Ely)—Both the North and South Chandler mines have raised miners' pay 30c. a day. They have heretofore paid $2.10 to $2.40, and raise is to meet wages of $2.40 to $2.80 paid by the Steel Corporation mines in district. It has been many years since an increase in wages has been made in fall of year.

MONTANA

MONTANA-CANADIAN OIL (Sweet Grass)—Fine flow of gas obtained Nov. 10 in company's well. Is taken as sure indication of presence of oil. Gas will be used from now on for firing boilers that supply power for drilling, thus saving $1,000 a month in operating expenses. Company's well is now down 1,500 ft. Nearest adjoining well struck oil at 1,735 ft.

Fergus County

BARNES KING DEVELOPMENT (Kendall)—During October 4,128 tons of ore, averaging $8.84 a ton, were mined and milled at North Moccasin mine. Total includes 873 tons of ore requiring roasting which averaged $1.42 a ton. Bullion estimated at $33,000. At Piegan-Gloster property near Marysville, 2,437 tons of ore were mined and milled averaging $7.51 a ton. Bullion estimated at $11,000.

Silver Bow County

ALICE (Butte)—No offers having been made at public sale held Nov. 10 in front of federal building at Butte, under terms of court's decree property reverts to Anaconda.

EAST BUTTE (Butte)—Net earnings of company for quarter ended Sept. 30 were $423,000. September net was $170,000, largest for any month on record, but exceeding July figure by only $6,000.

NORTH BUTTE (Butte)—According to report for quarter ended Sept. 30, company shipped 115,796 wet tons of ore and 27½ wet tons of precipitates. It treated 113,002 dry tons of ore and 19.6 dry tons of precipitates. Of ore, 12% was first-class and 88% second-class. Ore and precipitates produced 5,672,890 lb. of copper, 265,855 oz. of silver and 305 oz. of gold.

NEVADA

Esmeralda County

ATLANTA MINES (Goldfield)—Stoping has been started on 1,550 and 1,626 levels and shipments are to be resumed at once. Expect to maintain grade of $35 per ton.

GOLDFIELD CONSOLIDATED (Goldfield)—Preliminary estimate for October shows production of 36,500 tons of gross value of $256,000; with profit of $101,000. Red Top claim and adjoining north-end ground has again become large producer on company account from territory largely given over to leasers for last two years.

Humboldt County

SEVEN TROUGHS COALITION (Seven Troughs)—Produced $60,000 in October; banner month in history of mine. The next nearest approach was December, 1914. Between 1,200 and 1,300 levels, shoot 1 to 3 ft. wide and bringing returns of $300 to $1,000 a ton discovered.

ROCHESTER MINES (Rochester)—By reason of delays in transportation of ores necessitating closing down of mill for several days, output for October was only $40,000. With discovery of rich orebodies of unusual extent in deep levels and improvement of hauling facilities on Nevada Short Line railroad, there is every reason to anticipate production of $2,000 per day for November.

Nye County

TONOPAH ORE PRODUCTION for week ended Nov. 6 amounted to 10,343 tons valued at $212,134 compared with 9,891 tons week previous. Producers were: Tonopah Belmont, 2,990 tons; Tonopah Mining, 3,230; Tonopah Extension, 1,850; West End, 904; Jim Butler, 1,100; Halifax, 50; and miscellaneous leasers, 219 tons.

TONOPAH EXTENSION (Tonopah)—Installation of 20-drill compressor at No. 2 shaft about completed. Additional equipment being installed at mill expected to increase capacity materially. September profits amounted to $52,000. Developments during October showed steady improvement in general mine conditions, with mill products for latter half of month valued at about $80,000.

Storey County

ANDES (Virginia)—Saved 14 cars of ore from stope above 170 level.

OPHIR (Virginia)—Saved 343 cars of ore from north drift on 250 level, Central tunnel; milled 280 tons.

MEXICAN (Virginia)—Exploration work continued on 2,500 and 2,700 level. Mill crushed 252 tons of custom ore, average assay value $18.56 per ton.

CROWN POINT-BELCHER (Gold Hill)—Reopening north drift 1,600 level, leading to stopes. Water held 65 ft. below 1,600 level. Mill rock taken from 1,300 and 1,400 levels. Mill received 976 tons dump rock and shipped one bar bullion.

UNION CON. (Virginia)—Extracted 59 tons of ore averaging $24.60 per ton from No. 1 stope, 2,500 level; 181 cars sampling $13.72 per ton from No. 3 stope. West crosscut in No. 1 raise in low-grade ore, selected samples north side assayed $24.05 per ton, and from top $45.16 per ton.

SIERRA NEVADA (Virginia)—Northwest drift on 2,500 level advanced to 20-ft. point; face in ore averaging $31 per ton; saved 40 cars of ore averaging $33 per ton. Jointly with Union, raise to 2,450-ft. level continued and into quartz of low assay value.

NEW MEXICO

Grant County

DARK THUNDER MOUNTAIN (Twin Peaks)—Paul Crowley, of Duncan, Ariz., claims to have discovered enormous deposit of low-grade zinc ore on Dark Thunder Mountain.

CARLISLE GROUP (Silver City)—Announced by George Utter that he has sold Carlisle group to an Eastern syndicate for $300,000. Purchasers are represented here by W. B. Duvall, who will soon place order for mill, machinery and other equipment. Construction of branch railroad to mines is contemplated.

Lincoln County

RITA MINING (White Oaks)—Rita Mining Co. is negotiating for sale of its rich mineral holdings to W. M. McDonald, of El Paso, and associates. Its group of claims embraces 60 acres.

MINING TUNGSTEN ORES (White Oaks)—Richard Wightman and syndicate of New York men have just closed deal for purchase of Old Abe, North and South Homestake and Wilson mines from John Y. Hewitt and associates. New owners have began mining operations on large scale and it is their object to develop tungsten ores which are known to exist in North and South Homestake mines. Plans being made for modern mill and cyanide plant for treating gold ores.

SOUTH DAKOTA

Custer County

OLD MIKE (Custer)—J. W. McBride has taken over this mica property and has commenced development. A shaft is being sunk and hoisting apparatus and compressor being added

UTAH

Box Elder County

WEST CENTURY (Park Valley)—Lease has been taken on this property by A. Allred. Development consists of tunnel 500 ft. long. Low-grade gold ore has been cut. It is expected to mill some of this at small mill on adjoining property.

Juab County

TINTIC ORE PRODUCTION for October amounted to 643 carloads, estimated at 32,150 tons valued at $800,000, compared with 506 cars in September, 648 in August, 817 in July and 2,790 for the first half of 1915. There were 25 shippers as follows: Chief Consolidated, 126 cars; Iron Blossom, 115; Centennial-Eureka, 88; Mammoth, 81; Eagle & Blue Bell, 72; Gemini, 35; Grand Central, 27; Yankee, 18; Gold Chain, 14; May Day, 13; Dragon Consolidated, 12; Beck Tunnel, 8; Lower Mammoth, 7; Victoria, 5; Colorado, 4; Uncle Sam, 3; Utah Miner Co., 3; Bullion Beck, 3; Carisa Lease, 2; Eureka Hill, 1; Godiva, 1; Ridge & Valley, 1; Sioux mill dump, 1; Minnie Moore lease, 1; Cliff lease, 1 car.

TINTIC MILLING (Silver City)—Steel work is being erected at leaching section of this mill.

BECK TUNNEL (Eureka)—This company is developing ground on the 1,100. Leasers are working in various parts of the mine as usual.

IRON BLOSSOM (Silver City)—Preparations are being made for stoping ore opened on the 900 level, from the winze below the 600. The ore carries up to 8 and 12% copper.

IRON BLOSSOM (Silver City)—Copper ore has been opened on 900 level of No. 3 workings. This is reached by winze from 600, reported to have passed through 14 ft. of ore.

CHIEF CONSOLIDATED (Eureka)—Shipments for the first 10 months of 1915 amounted to 831 cars or about 41,500 tons. Arrangements for electrifying the compressor will soon be completed.

RIDGE & VALLEY (Eureka)—Value of ore mined on 1650 is increasing, returns now being over $1,200 per car, instead of $1,000 as heretofore. Principal contents are lead and silver.

EAGLE & BLUE BELL (Eureka)—Work has been started on power line between substation, owned jointly with Chief Consolidated, and new Eagle & Blue Bell 300-hp. hoist. Work is being done by Utah Power and Light Co.

YANKEE CONSOLIDATED (Eureka)—Connections have been completed between raise and winze, which allows ore to be sent out from new strike. Prospecting is being done on east side of property in search of Beck Tunnel ore channel.

Salt Lake County

A FOOT OF SNOW FELL at Alta Nov. 10; 8 in. fell in south fork of Big Cottonwood, and 2 ft. at Brighton. This will not interfere materially with ore hauling.

MICHIGAN-UTAH (Alta)—Nine bids have been received for proposed extension work in this company's lower tunnel. These varied from $9 to $13 a foot.

EMMA (Alta)—Men were started to clean out tunnels Nov. 6, preparatory to beginning work at this property. A. O. Jacobson and associates have made arrangements to operate.

SOUTH HECLA (Alta)—Shipments of 40 tons of ore daily are being maintained from the Wedge workings. Development is being done on 200 level, where vein reaches 25 ft. in width. This ore has been opened up for 185 ft. Lessees on Kate Hayes fissure have recently shipped 15 tons.

EMMA COPPER (Alta)—Development is in progress at this property, adjoining the old Emma. Several contracts for work have been let recently, and operations will be continued during winter. Drift from north crosscut is in mineralized ground, on contact of white and gray limestone.

OHIO COPPER (Bingham)—An experimental flotation plant using Field process is to be tried at this company's mill at Lark. Capacity will be 25 tons per day. Experimental work will probably be done on Ohio Copper tailings, as well as on low-grade ore at present being treated.

Summit County

PARK CITY ORE PRODUCTION for October amounted to 9,762 tons, valued at $390,000 compared to 8,000 tons in September. The producers were: Silver King Coalition, 2,742 tons; Daly-Judge, 2,724; Silver King Consolidated, 1,687; Daly West, 1,074; D. W. Quincy, 35; Daly, 120; Big Four Exploration, 1,000; miscellaneous, 380 tons.

CANADA

Ontario

CANADIAN COPPER (Sudbury)—In October sank new main shaft 165 ft.; shaft is 30x10 ft. in clear.

BRUCE MINES (Sault Ste. Marie)—Have been purchased by Mond Nickel Co. Ore, high in silica, carries from 3 to 4% of copper.

PLENAURUM (Porcupine)—This mine shaft, 200 ft. deep, is being pumped out for sampling on behalf of La Rose which may purchase property.

DOME (Porcupine)—Bullion production during October was highest on record, being $150,500, from 28,750 tons of ore; average $5.24 per ton.

CHENEY COPPER (Sault Ste. Marie)—Is under option to the Timmins-McMartin syndicate. Tenders have been asked for diamond drilling but no contract has as yet been let.

TECK HUGHES (Kirkland Lake)—Foundation for cyanide mill completed. Work on power plant delayed pending decision as to whether it will be possible to obtain electric power.

MINING CORPORATION OF CANADA (Cobalt)—This company which controls Cobalt Townsite, City of Cobalt and Cobalt Lake mines, has discharged all Austrians and Germans in its employ. Order, which came from head office in England, affects about 50 men.

The Market Report

Metal Markets

NEW YORK—Nov. 17

All of the principal metal markets experienced sharp advances during the last week which were scored in the transaction of large volumes of business. In copper especially the week was rather spectacular.

Copper, Tin, Lead and Zinc

Copper—On Nov. 11 the market had become well established at 18¼c., regular terms, for domestic deliveries, especially prompt deliveries, but forward business was taken at small concessions, as was also some foreign busines when figured out to the cash equivalent, f.o.b., New York. The volume of business continued to swell, and increased day by day, the price rising with it. On Nov. 15 the advance began to be rather violent. At the opening of that day copper was sold at about 18.45c., regular terms. By the end of the day, 18¾c. was realized in some cases, although the market did not become firmly established at that figure. On Nov. 16, business was done at 18⅝c., regular terms, and even a shade lower, early in the day, but later sales of million-pound lots were made at 19c. It was expected that there would be a rush of buying on Wednesday, but instead thereof the market became rather quiet, with the price firm at 19c. regular terms, equivalent to 18.75@18.80c. cash, New York.

The aggregate of business transacted during the week was very large, the estimates in several quarters agreeing upon something like 50 to 70 million pounds. Sales to domestic consumers predominated and it was especially noteworthy that some very large business was done with the wire drawers.

Certain sellers of copper are now adopting the policy of doing their business with France only in terms of dollars per ton.

The strike at the Nichols refinery was settled on Nov. 16.

Shipments from Baltimore for the week included 7,847,765 lb. copper to France.

Copper Sheets, base price is 23½c. per lb. for hot rolled and 24½c. for cold rolled, with usual extras. Copper wire is 19@19½c. per lb., carload lots at mill.

Copper Exports from the United States week ended Oct. 30 are reported by the Department of Commerce at 13,657,586 lb. The larger items were 5,551,235 lb. to Franee, 2,930,833 lb. to Russia; 1,996,644 lb. to Sweden, 1,301,411 lb. to England; 1,121,329 lb. to Italy. Imports for the week were 8,498,268 lb. metal and 824,444 lb. in ore and matte; 9,322,712 lb. in all. The chief imports were from Peru, Canada and Chile.

Tin—In this market there was a sharp advance, caused by an urgent demand and the shortage of supply for near-by deliveries. Rumors respecting the Suez Canal also played a part. When it was learned that the canal was open and had not been closed at all, the market receded from its highest point.

Tin production of Federated Malay States nine months ended Sept. 30 is reported at 36,692 long tons in 1914, and 34,840 tons in 1915; deerease, 1,852 tons.

Corrected statement of tin exports from the Straits eight months ended Aug. 31: United States, 19,313; Great Britain, 18,234; other Europe, 6,651; China, 58; India, 862; total, 45,118 long tons, an increase of 1,457 tons over last year.

Lead—Following the advance to 5.15c., New York, independent producers tried to see if they could get a little more and found that they could. The demand for lead was ,indeed, so good, and the transactions so large, that the A. S. & R. Co. felt itself warranted in advancing the price to 5.25c. on Nov. 15. The aggregate of business transacted during the week was very large.

The Chinese Lead Markets are reported badly demoralized by lack of supplies. This has resulted from the order of the Australian Government prohibiting lead exports.

Spelter—A pretty good volume of business was transacted up to and inclusive of Nov. 15. Some sales for export were made and also some considerable sales to important domestic consumers, including certain galvanizers. The bulk of the business was for January-March delivery, and the nature of the demand was sufficient to produce a considerable advance in price. Since Monday the market has been dull and quiet, and a shade weaker in tone.

The Donora plant of the United States Steel Corporation is now producing spelter regularly, and its output will increase month by month, but it will probably not be running at full capacity before next April.

Zinc Sheets were advanced 1c. per lb. on Nov. 13, to $18 per 100 lb. On Nov. 17 the price was again advanced 1c., making it $19 per 100 lb. f.o.b. Peru, Ill., less 8% discount.

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies, and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St Louis is given as the basing point St Louis and New York are normally quoted 0 17c. apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash The difference between the price delivered and the New York cash equivalent is at present about 0.20c. on domestic business The price of electrolytic cathodes is 0.05 to 0.10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St Louis being the basing market We quote the New York price at 17c per 100 lb. above the St Louis price.

Silver quotations are in cents per troy ounce of fine silver

Some current freight rates on metals per 100 lb. are: St Louis-New York 17c.; St Louis-Chicago, 6.3c.; St Louis-Pittsburgh, 13.1c.

15	24½	78½	78¾	91½	18 97	176¼	175	26½	5 57	86	17.84
16	24½	78¾	78	92	19 09	172¾	171½	27¼	5 63	86	17.85
17	24¾	79¾	79¾	92	19 13	174½	173¼	27	5 61	86	17.88

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 3 per cent. discount. For convenience in comparison of London prices, in pounds sterling per 2240 lb., with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4.80: £15 = 3.21c.; £20 = 4.29c.; £30 = 6.43c.; £40 = 8.57c.; £60 = 12.85c Variations, £1 = 0.21½c.

Other Metals

NEW YORK—Nov. 17

Aluminum—Supplies for early delivery continue scarce. Prices are fully maintained and even stiffened, 57@59c. having been paid for No. 1 ingots for spot delivery.

Antimony—The market is very firm. Stocks here are low and metal for immediate shipment is hard to get. Quotations for Chinese and other ordinary brands are 37½@38½c. per lb. Cookson's is held at 45c. per lb. nominally.

Antimony ore is only offered in very small quantities, at $2.25@2.35 per unit.

Quicksilver—The market is strong and stocks are small. New York price is $105 per flask of 75 lb. for large lots; $105 @110 for smaller orders. San Francisco reports by telegraph $100 per flask, with the market very firm. London price is £16 10s. per flask, with no discount from second hands.

Nickel—There is no change reported. Ordinary forms are nominally 45@50c. per lb. according to size and terms of order. A premium of 3c. per lb. is charged for electrolytic nickel.

Minor Metals—Current quotations for **Bismuth** are $3 per lb., New York.—**Cadmium** is quoted at 7s. per lb. in London; $1.75@1.90 per lb., New York.—**Chromium** metal, 75c. per lb., New York.—**Cobalt** metal, 97% pure, is sold at $2 per lb.—**Magnesium**, pure, has gone to a high price, $6 per lb. being asked.

EXPORTS AND IMPORTS

Exports and Imports of Copper in September are reported by the Department of Commerce as below, in pounds:

	Imports	Exports
Ore, copper content	10,503,225	315,651
Matte, copper content	1,706,689	.....
Unrefined, blister copper, etc.	25,529,234	2,168
Refined	786,560	49,441,194
Old scrap, etc.	663,658	10,625
Total	39,189,366	49,769,638

In addition to the quantities given, manufactures of copper valued at $631,258 were exported; quantities not being given. This makes the exports of copper for the nine months ended Sept. 30 a total of 216,260 long tons; imports, 106,371 tons.

Imports of Lead in September are reported by the Department of Commerce as below, in pounds:

Lead in ore	1,095,649
Lead in base bullion	10,728,927
Lead, metallic	27,944
Total	11,852,520

The total imports for the nine months ended Sept. 30 were 37,572 short tons. The base bullion was nearly all from Mexico.

Imports and Exports of Zinc in September are reported by the Department of Commerce as below, in pounds:

	Imports	Exports
Zinc contents of ore	8,826,329	1,218,500
Zinc, metallic	225,689	20,332,761
Total	9,052,018	21,551,261
Zinc dust	267,774	78,220
Zinc dross	.....	886,778

Total weight of ore imported was 15,753 tons; 5,112 tons being from Mexico, 5,023 from Australia, 4,743 from Spain, 874 from Canada, and 1 ton from Japan. For the nine months ended Sept. 30 the total exports were 90,696 short tons; imports, 32,416 tons, nearly all in ore.

Exports and Imports of the Principal Metals, other than iron and steel, eight months ended Aug. 31, copper and tin in long tons, lead and zinc in short tons:

	Exports		Imports	
	1914	1915	1914	1915
Copper	284,910	194,041	104,789	87,626
Tin	486	502	28,939	33,576
Lead	46,395	86,059	15,635	34,646
Zinc	4,455	79,920	760	607
Ores:				
Zinc	8,490	605	12,483	77,468
Zinc ore, contents			4,503	31,809

Exports include reexports of foreign material. Copper includes contents of ore and matte; lead, contents of ore and base bullion.

Shipments of tin from the Straits 10 months ended Oct. 31—estimating October—were 51,127 long tons, in 1914, and 54,060 in 1915; increase, 2,933 tons.

Gold, Silver and Platinum

NEW YORK—Nov. 17

Gold is still coming here from London. A further shipment of $3,800,000 was made on Nov. 12, and more is reported this week.

Platinum continues high, with supplies scarce and the future uncertain. Sales are small, and prices continue rather nominal at $55@60 per oz. for refined platinum; $60@63 per oz. for hard metal.

Our Russian correspondent writes under date of Oct. 22 that the market is very firm and advancing. The demand both for the domestic market and for export has increased enormously, and the offers of metal are not up to the needs of the market. On Oct. 16 a total of five poods was sold at 52,000 rubles per pood. The quotations at Ekaterinburg are 13@13.25 rubles per zolotnik; at Petrograd, 52,000@53,000 rubles per pood, for crude metal, 83% platinum. These prices are equal to $49.35 and $51.45 per oz., average.

Silver has shown a rising tendency the past week, owing to a more active London demand and reduction in the stocks held in that city. The advance in English exchange has also contributed to an improvement in the New York equivalent price of the London official.

Zinc and Lead Ore Markets

JOPLIN, MO.—Nov. 13

Blende, high price $112.50; base per ton 60% zinc, premium ore, $110; medium, $109@100; lower grades down to $90; calamine, base per ton 40% zinc, $60@70; average selling price, all grades of zinc, $97.49 per ton. Lead, high selling price, $62.50, bids today as high as $64 base per ton of 80% metal content; average selling price, all grades of lead, $60.55 per ton.

SHIPMENTS WEEK ENDED NOV. 13

	Blende	Calamine	Lead	Values
Totals this week.	14,307,340	714,090	2,066,750	$794,790
Totals this year.	506,481,690	36,423,080	78,789,770	22,647,380

Blende value, the week, $711,750; 46 weeks, $19,692,000.

Calamine value, the week, $20,490; 46 weeks, $880,230.

Lead value, the week, $62,550; 46 weeks, $2,074,150.

Sellers are very well satisfied with the market for both zinc and lead. Zinc was advanced another $10 this week and lead was advanced $4 per ton today for next week's delivery. The enormous shipment is largely attributable to the United States Smelting, Refining and Mining Co.'s heavy purchases the past three weeks. This week this company was practically out of the market, but this was not known until late in the week by the agents of other smelting companies. Today blende of 62% zinc and no lead was being offered at $105 base, a grade of ore purchased yesterday at $110 base.

PLATTEVILLE, WIS.—Nov. 13

The base price paid this week for 60% grades of zinc ore advanced from $88 to $100 per ton at week end. The base price paid for 80% lead ore was $58 per ton.

SHIPMENTS, WEEK ENDED, NOV. 13

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	4,738,400	.....	1,790,100
Year	178,771,750	6,028,540	24,862,690

Shipped during week to separating plants, 4,872,000 lb. zinc ore.

Iron Trade Review

NEW YORK—Nov. 17

The iron and steel trades continue extremely active, with both foreign and domestic demand strong and prices inclined to advance still further.

The following statement has been issued: "The United States Steel Products Co. has recalled, temporarily, quotations in French markets, except as to pipe, tinplate, and some specialties that involve a small tonnage, for the reason that steel products for delivery in the near future are sold well up to maximum capacity. Until the general questions of supply and demand are carefully considered it is impossible to tell how much surplus we shall have for sale in France for the present."

The new works of the Steel Corporation at Duluth, Minn., are almost ready to start and will probably be making steel ingots and billets next week.

The United States Steel Corporation announces that two blast furnaces and several openhearth furnaces are to be added to the equipment of the Gary works, and some other improvements.

It appears that the control of the Cambria Steel Co. is not yet decided. We noted last week the sale of 112,000 shares by the Pennsylvania R.R. Co. to W. H. Downer, now president of the Cambria. This week a further sale of 250,000 shares was made to a syndicate represented by J. L. Replogle, formerly vice-president of the Cambria and now president of the Vanadium Steel Co. With him are associated some prominent Philadelphia and Pittsburgh steel men. Neither party now holds a majority of the stock. Reports as to the sale of the Pennsylvania Steel Co. have been current, but have not been confirmed.

Alabama pig-iron production for the 10 months ended Oct. 31 was 1,600,712 tons. The make of iron is now at the rate of about 200,000 tons a month.

The United States Steel Corporation reports unfilled orders on its books Oct. 31 at 6,165,452 tons of material; an increase of 847,834 tons over Sept. 30, and the highest monthly report made since May, 1913, over two years ago.

Exports and Imports of those articles of iron and steel for which tonnages are given in the Commerce reports were as follows for September and the nine months ended Sept. 30, in long tons; values of exports of machinery are added:

	September		Nine Months	
	1914	1915	1914	1915
Imports, iron and steel	38,420	31,814	234,282	183,997
Exports, iron and steel	96,482	381,317	1,142,979	2,461,198
Exports, machinery, values	$5,295,167	$12,377,389	$72,617,657	$91,673,678

Exports of mining machinery, including oil-well machinery for the nine months were valued at $5,934,748 in 1914, and $4,950,076 this year.

FOREIGN IRON

Pig Iron Production in Germany in September was 1,033,078 metric tons, being 17,532 tons less than in August, and 452,991 tons more than in September, 1914. For the nine months ended Sept. 31 the total production this year was: Foundry, 1,776,034; forge, 218,964; steel pig, 1,244,275; bessemer pig, 135,162; Thomas (basic) pig, 5,291,093; total, 8,665,528 tons. The total in 1915 was 12,016,888 tons, showing a decrease of 3,351,360 tons, or 27.7%, this year.

Exports of Iron Ore from Sweden in the six months ended June 30 were 2,027,000 tons, a decrease of 501,000 tons from last year. Imports of coal were 2,243,000 tons, an increase of 108,000 tons from last year.

Imports of Iron and Steel into Italy for the six months ended June 30 were 336,164 tons. Imports of coal were 4,119,110 tons, being 1,285,360 tons less than last year.

British Foreign Trade in Iron and Steel and in manufactures thereof for the nine months ended Sept. 30 are valued by the Board of Trade returns as follows:

	Exports	Imports	Excess
Iron and steel	£28,794,063	£7,844,353	Exp. £20,949,710
Machinery, hardware, etc.	21,842,751	11,377,041	Exp. 10,465,710
Totals	£50,636,814	£19,221,394	Exp. £31,415,420
Totals, 1914	73,204,394	20,526,543	Exp. 52,677,851

Quantities of iron and steel exported were 3,179,726 long tons in 1914, and 2,333,529 tons in 1915. Quantities imported were 1,467,412 tons in 1914, and 901,032 tons this year.

PITTSBURGH—Nov. 16

The October increase of 847,834 tons in the unfilled obligations of the Steel Corporation show the pace at which steel buying has proceeded, for the bookings, although so large, were chiefly of specific orders, there being an unusually small amount of contract tonnage. Only in two months in the past, December, 1911, and October, 1912, was there a larger increase, and in those months the business accepted was chiefly in the form of open contracts, subject to specification later.

This week witnesses a reduction in the pressure to buy steel products, the rush to get under cover having spent part of its force, while it meets increased reserve on the part of the steel mills as to selling. Some are practically out of the market. Very few will accept contract obligations and the trend is strongly toward a condition in which nothing marketwise will be done except by way of specific orders. Specifying against existing contracts shows no abatement. With these specifications and the specific orders placed the mills will enter the new year with from two to four months of actual work on books, according to the description of material, and even very light buying in the first six months of next year will not enable the mills to catch up by July 1. Steel prices continue to show an advancing tendency. The average price of finished steel products is now within $3 a ton of the highest level reached in 1907, and higher than at any high point since then.

The most important new business in sight is in freight cars. The Pennsylvania system is now opening bids on 9,000 cars but is expected to buy a larger number, as many as 25,000 being predicted in some quarters. There are many inquiries for relatively small lots. The railroads are disagreeably surprised at the strength of the steel market, finding that full market prices have to be paid for car material, while the mills will give options for only a few days at a time.

Pig Iron—The sharply advancing tendency in pig iron has been arrested and in bessemer there has been what amounts to a reaction from the higher prices reported a week ago. We quote: Bessemer, $16.50; basic, $16; foundry and malleable, $15.50@16; gray forge, $15@15.50, f.o.b. Valley furnaces, 95c. higher delivered Pittsburgh.

Steel—There continues to be buying of billets [illegible] t bars by mills that ordinarily make steel for their own consumption, the object being to release openhearth capacity to make forging and war billets. The latest buying of this sort has been by the Pittsburgh Steel Co., which has taken about 40,000 tons of bessemer billets from Youngstown and Wheeling mills, to use in its wire department, releasing so much openhearth steel-making capacity for other purposes. Current prices are approximately as follows: Bessemer billets, $25.50@26.50; sheet bars, $26@26.50; openhearth billets, $26.50@27.50; sheet bars, $27@27.50, at maker's mill, Pittsburgh or Youngstown; forging billets, $42@45; rods, $35 at mill.

IRON ORE

Shipments to furnaces from Lake Erie docks have been large, and the stock on docks is being drawn down rather low. Some furnaces which have been looking for additional tonnage this year have not been able to get it.

Of the October shipments of Lake Superior ore a total of 5,741,176 tons, or 80.3%, were delivered to Lake Erie docks.

Imports at Baltimore for the past week included 23,958 tons manganese ore from Brazil.

Imports at Baltimore included 35,775 tons iron ore, of which 5,785 tons were from Algeria and 29,990 tons from Cuba.

OTHER ORES

Molybdenum and Tungsten ores mined in Australia are now all taken by the Commonwealth government under an agreement with the British government. No exports of these ores will be allowed except through the government agents, Dalgety & Co., Ltd. The arrangement is for one year from Sept. 9, 1916. The prices fixed by the government are: Molydenite, 90% MoS_2, 105s.—$25.20—per unit; Wolframite, 65% WO_3, or scheelite, same grade, 55s.—$13.20—per unit.

Prices here are a decided contrast to these. We noted last week a sale of **Tungsten** ore at $38 per unit, and have since heard of sale of ore, 60% WO_3 at $45 per unit.

NEW CALEDONIA ORES

Shipments of chrome ore from New Caledonia in August were 11,195 metric tons, all to the United States. For the eight months ended Aug. 31 shipments were 40,024 tons chrome ore and 39,216 tons nickel ore. Shipments of nickel matte were 2,710 tons.

COKE

Coke production in the Connellsville region for the week is reported by the "Courier" at 424,162 short tons; shipments, 426,093 tons. Shipments of Greensburg and Upper Connellsville districts, 45,022 tons.

Connellsville—The market for prompt furnace coke is decidedly softer, with fair offerings at $2.25 and little demand. Corrigan, McKinney & Co. are understood to have closed for at least half their requirements for 1916 with the Rainey interest. The Youngstown Sheet and Tube Co. is reported to have renewed its contracts, involving a total of about 75,000 tons a month, with Hillman and Producers, for the first three months of 1916 at about $2.50, this carrying the company to the time when its new byproduct plant is expected to be operating. Foundry coke is quotable at $3@3.25 for both prompt and first-half contracts.

Chemicals

NEW YORK—Nov. 17

The general markets show little change from our last report. The chief business now is in contracts for next year's delivery of heavy chemicals.

Arsenic—Only a moderate business is forward. Prices are steady and unchanged at $3.75@4 per 100 lb. for both spot and futures.

Copper Sulphate—Business is good for the season and the market is steady. Current quotations are $7 per 100 lb. for carload lots and $7.25 per 100 lb. for smaller parcels.

Nitrate of Soda—The market is rather active and sales are steady. Quotations are firm at $2.90 per 100 lb. for spot and December; and $2.85 per 100 lb. for January and later deliveries.

Imports and Exports of Raw Materials for chemical manufacture in the United States eight months ended Aug. 31, in long tons:

	Imports		Exports	
	1914	1915	1914	1915
Sulphur	14,583	17,736	95,176	9,414
Pyrites	667,036	600,558		150
Chrome ore	48,081	30,089		
Magnesite	90,522	19,287	1,196	412

Exports include reexports of foreign material. Estimating sulphur contents of pyrites, the total imports of sulphur in 1915 were 257,958 tons.

Stock Quotations

The copper and lead stocks have advanced sensationally this week, and apparently the end is not in sight. Coppers always look best with the metal at 20c. per lb.

The Engineering and Mining Journal

VOLUME 100 NOVEMBER 27, 1915 NUMBER 22

Building the Tough-Oakes Mill—I

By John A. Baker*

SYNOPSIS—In building the Tough-Oakes mill, a 100-ton cyanide plant, arrangements were made for keeping a detailed chronological record and a segregated cost account. Cost of ground clearing, concreting for foundations, building construction, and general costs are given with extreme clarity, the time factor also being definitely determined.

The property of the Tough-Oakes Gold Mines is in the Kirkland Lake gold area, in the district of Timiskaming, Ont., Can. This district is about 50 mi. north of Cobalt, and the Tough-Oakes mine, at present the sole producer, is in the eastern portion of the area, between Kirkland and Gull lakes. A good wagon road, built by the Ontario government, connects the mine with the village of Swastika, about seven miles away, on the main line of the Temiskaming & Northern Ontario Ry. The area is just south of the Height of Land, separating the waters of the St. Lawrence from those of Hudson Bay. Crushing at the newly constructed 100-ton cyanide plant of this company was begun on Mar. 15, 1915, slightly over three years from the date of discovery of gold on the property and 29 months from the inception of mining operations there.

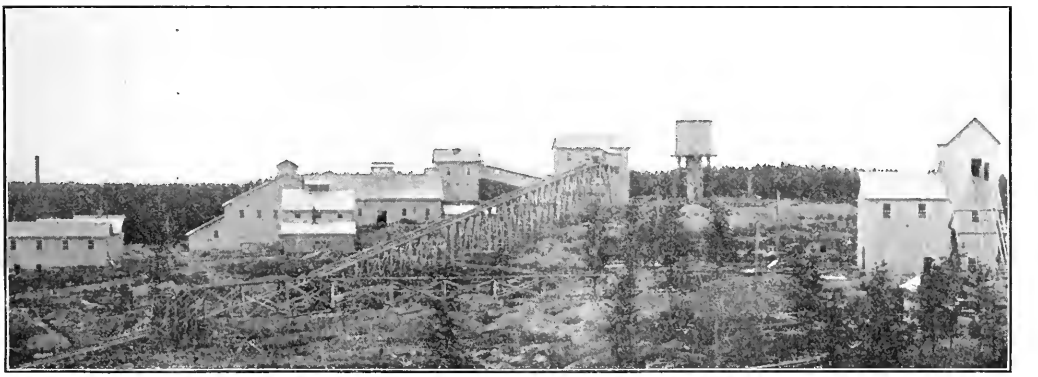
Development of the Tough-Oakes property progressed through the ordinary steps usual in such cases, including the construction of a small amalgamating mill; but the prospective value of the mine increased so rapidly that the present mill was decided upon and construction begun in a much shorter period than is usual with mines of the kind. The customary cyanide experiments and grinding tests were made. These, together with the quick-setting properties of the ore, indicated that the continuous counter current decantation process was applicable. Ball-mill crushing was looked upon with favor on account of the low first cost and the success of some similar mills at Porcupine. In view of guarantees given by manufacturers it was decided to install Hardinge ball mill instead of stamps.

The Butters-Johnston Engineering Syndicate was engaged as consulting engineers and metallurgists.

The necessity for having the mill in operation at the earliest possible moment led Mr. James Johnston to accept the opinion already arrived at as regards process and machinery, this opinion being later corroborated by the experimental tests made by his company.

While the utmost economy was aimed at in all that pertained to the designs and their execution, quality in machinery and material was never sacrificed to cheapness where any advantage or efficiency in operation was to be gained by the former.

Since the doubling of the mill was considered a not remote possibility, provision was made in the organic design and in power line, transformer station and pipe lines for this contingency. Particular care was taken with the estimate, and a detailed cost-keeping system was installed. A construction schedule was drawn up, and shipments of machinery were planned in accordance with it. By this means it was possible to estimate the monthly



SURFACE PLANT OF THE TOUGH-OAKES MINE, KIRKLAND LAKE, ONT., SHOWING THE SHAFT HOUSE, MILL BUILDINGS, TRESTLES AND BOILER PLANT

*Formerly Construction Engineer, Tough-Oakes Gold Mines, Ltd.

expenditures considerably in advance, thus aiding financial arrangements. A careful daily diary, or log, of all events taking place at the mill site was written up each day. This record enabled the construction engineer to look back and visualize the state of progress at any time, and from that intelligently to predict future progress. It contains the starting and finishing date for every portion of the work, record of arrival and supplies of machinery, had many valuable data, particularly regarding the time factor, which in the rush of construction work is usually lost unless its systematic recording is insisted upon.

General Description of Site and Mill

The mill is on a rocky gently sloping hillside about 1,000 ft. north of the main shaft. From this shaft the ore is delivered along an inclined trestle by a self-dumping skip. An intermediate pocket permits handling ore from No. 3 shaft over the same trestle. The crusher station occupies a separate building connected with the cyanide plant by an overhead conveyor. The cyanide plant is built in the shape of a letter L, the eastern wing comprising the fine-ore bin, ball mill, tube mills and plates and is referred to as the fine-grinding department. The main building houses the tanks, pumps and accessory apparatus.

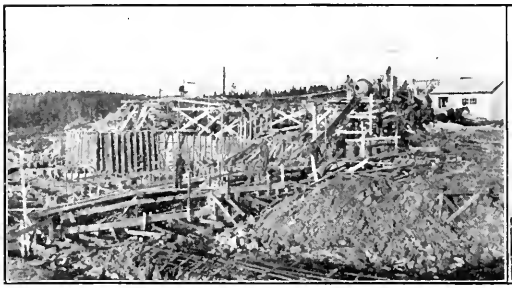
In the crusher station run-of-mine ore is reduced to 1¼-in. ring by two jaw crushers, with intermediate elevating and screening. The crushed ore is delivered by belt conveyor to the fines-storage bin at the end of the fine-grinding department. From it push feeders deliver to a short conveyor feeding the ball mill. The ball-mill product is split between two duplex Dorr classifiers, each operating in closed circuit with a 5x20-ft. tube mill. An elevator and copper plates are provided, so arranged that the plates may be interposed between either tube-mill discharge and its classifier. The classifier overflow runs by gravity into a 30x10-ft. Dorr thickener. The overflow of this machine, constituting the pregnant solution, gravitates to a box containing canvas leaves for clarifying. From this a vacuum pump delivers the clear solution to a sump, from which it is drawn for precipitation. The zinc-dust system is used.

Thickened pulp from the bottom of the 30x10-ft. collector thickener is transferred by diaphragm pumps to three 16x12-ft. agitators operating continuously in series. The pulp from the third agitator gravitates to the first of four 28x10-ft. Dorr thickeners, operating on the continuous counter-current decantation principle. Each tank is 24 in. higher than the preceding one. The overflow runs by gravity, while the thickened-pulp transfers are effected by diaphragm pumps. From the final tank the thickened pulp is discharged by spigot into a launder, whence it runs through a mechanical sampling device and then to waste.

Below and to the west of the cyanide plant are the heating boiler, transformer house and the carpenter and machine shops. Next to the crusher station are the office and storehouses, water tank and lime bin. All these auxiliary buildings, together with the water-service pipe, 2,200-volt mill-feeder line and trestle are included under the general heading of mill construction in the original estimate. The refinery and oilhouse were added later when the financial situation had improved.

Clearing and Excavating for Foundations

Clearing of stumps and removing of soil was commenced on July 27, 1914, with a gang of 12 laborers and one team. Under about 6 in. of top soil a tough boulder clay was encountered. Work was found to progress most satisfactorily when using two teams and about a dozen men. The soil was deposited about 100 ft. outside the lines of the building, where it could be recovered handily for filling purposes. On portions of the work wheelbarrow runways were employed instead of teams, to dispose of material. Frequent boulders and the uneven nature of the ground prevented the use of scrapers or similar devices. The average depth of the overburden over the whole area cleared was 2 ft., giving a total of 1,278 cu.yd. The cost of the work was: Labor, $820.19; material, $99.60; total, $919.79; or 72c. per cu.yd. Laborers were paid at the rate of $2.25 per day.



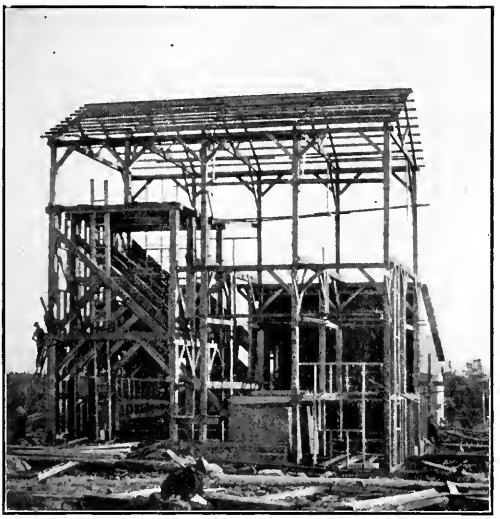
POURING THE CONCRETE MILL FOUNDATIONS THROUGH A CHUTE FROM THE MIXER

CONSTRUCTION OF TANK ROOM, CRUSHER STATION IN THE BACKGROUND

Work on rock excavation was begun immediately, using hopper drills of the hand-rotated type. After Sept. 1, air was supplied from the original small steam plant, so that its cost per machine per shift was higher than when the large electric compressor was running, the exact figure being $3.50. There was no cut more than 6 ft. deep, but it was necessary to cut down from 1 to 2 ft. over nearly 60% of the area of the cyanide plant. A total of 125 machine shifts was necessary, and the complete work of rock excavating was not finished until Oct. 1, making an average of three machine shifts per day. Owing to the great irregularity of the rock surface, no close estimate of rock removed, based on cross-sections, can be given. The figures given herewith are believed to approach accuracy to within 15%: Total yardage, 547; labor and material, $3,001; cost per yard, $5.52. The rock was nearly all conglomerate.

On Sept. 20, while the drills were still working on the lower floor of the cyanide plant, carpenters commenced work on the crusher-station forms. Since the topography of the mill site is something over which the construction engineer had no control, the actual work of the mill construction may be said to start from this date.

One-inch rough lumber costing $24 per M laid down at the mill site was used in the forms. On walls up to 4 ft. high, 2x4-in. scantling on 18-in. centers was used. On walls 4 ft. to 10 ft. high, 2x6-in., 16-in. centers, securely tied together with concrete wire, was employed. On the main retaining wall between the fine-grinding department and the cyanide plant 2x8-in. timbers on 16-in. centers were found necessary to make the forms secure. This wall is 12 to 14 ft. in height. The uprights were tied from back to front in three places with soft-iron concrete wire. A rough reinforcement consisting of strands of old cable was fastened to these tie wires. This



THE CRUSHER STATION IN CONSTRUCTION STAGE

wall was given a batter of 1 in. per ft. The other walls, which varied in thickness from 6 to 12 in., were built with vertical sides.

All tanks are supported on packed rock and earth fill held in place by small retaining walls. Since all the tanks are on different elevations and since it is necessary to have a channel to the center of each thickener, the foundation plan presents a rather complicated appearance. This method, however, is much more economical than that using individual piers with timber beams and joists. The center channels are run obliquely, so that there will be only one elbow in the diaphragm-pump suction line.

All concrete was mixed in a Smith mixer of ⅓-cu.yd. capacity. The mixer was driven by steam from a 20-hp. locomotive boiler temporarily erected for construction purposes. The total for all walls, floors and piers was 445 cu.yd., divided among the several buildings as follows: Crushing station, 70; fine-grinding department, 135; cyanide plant, 215; water tank, 5; heating plant, 20; total, 445 cu.yd. Four different set-ups of the mixer were necessary. All the main walls and piers were spouted direct from the machine through wooden launders lined with galvanized iron. Some of the smaller walls were filled by wheelbarrow. A modern spouting equipment with steel chutes, hoist and tower, would have saved $200 in the placing of the concrete—not more. This, however, would have involved either a large outlay for equipment or the letting of the work by contract, which was for many reasons undesirable.

The mixture desired was 1 part cement, 3 of sand and 5 of rock. Large piers and walls were given as much additional coarse clean rock as they would stand. The rock used was from the main waste dump about 400 yd. away. It was hauled by team to the mill site and used without crushing or screening. The problem of securing suitable sand was not so simple. Two sources of supply were available and screen tests showed the results given in the accompanying table.

COMPARISON OF SANDS AVAILABLE FOR CONCRETE

	No. 1—Lake Sand, %	No. 2—Trench Sand, %
On 10-mesh	13 9	5 9
On 20-mesh	21 1	6 3
On 40-mesh	21 7	11 3
On 60-mesh	25 7	20 4
On 80-mesh	8 2	27 7
On 100-mesh	3 0	4 2
Through 100-mesh	6 2	22 7

No. 1 sand was two miles from the mill, was coarse and of a reddish color and seemingly the best. No. 2 sand was half a mile from the mill and was almost pure white. Despite the large proportion of —100-mesh it settled quickly in a glass of water, showing little or no colloidal matter. Test bricks were made from both sands without coarse aggregate, and that made with No. 2 appeared considerably the sounder of the two. It was finally decided to mix them in the proportion of 25% of No. 1 to 75% of No. 2. The resulting concrete was sound in every instance.

All floors were laid after the completion of the building and the installation of the heating system. As this was during January and February, hand mixing inside the building was resorted to. Floors were laid 5 in. thick in the usual proportion and then a surface coat ½ in. thick, of 1 of cement to 2 of screened sand, was floated on.

DATA ON CEMENT USED IN CONCRETE WORK

Total cement used	2,736 bags
Total cost of cement	$2,042.85
Cost per bag	0.74
Bags per yard	6.1
Total cost labor, $4,350.33; material, $2,870.31	$7,220.64
Total yardage including floors	445 cu.yd.
Cost per yard	$16.23

In this total cost of concrete no proportion of office, consulting, or general supervision expense was added and no credit is taken for the lumber rescued from the forms and used later in the building.

Sequence Planning for Rapid Construction

Returning now to the chronological description of the work, Sept. 25 saw the completion of the crusher-station forms and a start on those of the cyanide plant. Concrete pouring began on Oct. 2, and as soon as the crusher station was completed the mixer was shifted down to the next set-up and the forms filled as fast as finished. Form building was completed on Oct. 14 and the concrete on Oct. 15.

On Oct. 2, the same day on which concrete pouring was commenced, the framing of the crusher station was begun with a gang of six carpenters. On Oct. 12 the work of erection was commenced. The design of the building

permitted assembling the various members of the structure into frames or bents. The latter were then hoisted into their proper position with a gin pole and small hoist. On Oct. 20 the frame was up and sheeting had commenced.

The posts under the ore bin and the members of the ore-bin frame are 10x10-in. timbers. All other posts are 8x8-in. Mortise-and-tenon construction is employed throughout except on knee braces and roof trusses. In these the members are halved and bolted. All horizontal splices are ship splices, bolted with four ⅝-in. bolts and tightened with tapered hardwood wedges. All vertical splices are plain halved joints 24 in. long. The main plant consists of three buildings—the tankroom, fine-grinding department and the fine-ore storage bin. The main building, or tankroom, consists of a main span of 62 ft. with a shed addition 18 ft. wide along the western side, making a total width of 80 ft. It is 114 ft. in length. The fine-grinding department is 52 ft. long, with a span of 50 ft. The building has a general "L" shape, with limbs of 114x155 ft.

Working from both ends of the "L" with separate gangs of carpenters, the process of erection went forward rapidly. The completion of the crusher station was held in abeyance and every effort made to finish the cyanide-plant building so that the work of tank erection might be

TABLE 1. CYANIDE-PLANT AND CRUSHER-STATION COSTS

Building	Nature of Work	Labor	Material	Total	Supervision	Insurance	Heating	Total
Crusher station.	Clearing, excavations and foundations	$1,098.56	$1,065.29	$2,163.85				
	Building and erection	1,773.16	1,732.96	3,506.12				
	Machinery and equipment	1,792.24	5,786.73	7,578.97				
	Electrical equipment	65.60	856.68	922.28				
	Heating system	109.77	248.48	358.25				
	Crusher station, total	$4,839.33	$9,690.14	$14,529.47	$1,159.65	$43.52	$311.31	$16,043.95
Cyanide plant	Clearing, excavations and foundations	$6,832.11	$2,297.28	$9,129.39				
	Building and erection	4,624.97	4,815.65	9,440.62				
	Tanks	2,866.56	5,100.00	7,966.56				
	Machinery and equipment	7,316.44	35,287.77	42,604.21				
	Heating system	731.45	2,800.95	3,532.40				
	Electrical equipment	559.09	5,789.03	6,348.12				
	Cyanide plant, total	$22,930.62	$56,090.68	$79,021.30	$3,865.98	$145.07	$1,037.74	$84,070.09
	Combined total	27,769.95	65,780.82	93,550.77	5,025.63	188.59	1,349.05	100,114.04

Labor cost was 33% and material cost 67% of the total. Dividing into classes, the cost of supervision and insurance was 5.1%; clearing excavations and foundations, 11.3%; building and erection, 12.9%; tanks 8%; electrical equipment, 7.3%; heating during construction, 1.3%; heating system 3.9%; machinery and equipment, 50.2%.

TABLE 2. CONSTRUCTION COSTS

Building	Nature of Work	Labor	Material	Total	Supervision	Insurance	Heating	Total
Office	Building, furniture and fixtures	$253.05	$580.75	$833.80				
	Heating system	14.58	43.44	58.02				
	Total				$60.00	$4.85	$69.18	$1,025.85

	Building and erection	265.45	358.30	623.75				
	Boiler setting, boiler piping	759.09	1,313.70	2,072.79				
	Total				208.95	4.83	34.09	3,260.82
Combined totals		$7,120.09	$12,734.91	$19,855.00	$1,117.48	$53.21	$380.49	$21,706.18

roof-truss members are 4x8 in., and the roof has a ¼ pitch. Splices in truss members are fishplated, using 3x½-in. iron. Studding and purlins are of 2x6-in. timber on 24-in. centers. The sheeting of 1-in. rough lumber is put on diagonally to increase the stiffness. Floors are of double thickness—a layer of 1-in. boards being overlaid with another of 2-in. rough planks. The cornice is boxed in with ⅞-in. dressed lumber. A carefully made cornice is essential to economical heating, with the winter conditions obtaining in northern Ontario. Roof and walls are first covered with 16-oz. tar felt and then with No. 28 gage corrugated galvanized iron.

Erection work on the cyanide-plant frame was commenced on Oct. 22. The roof truss for the main 62-ft. span was completely framed on the ground and then lifted into position. Each truss weighs 2,200 lb. The main members are 4x10 in., but in all other respects the construction details are similar to those of the crusher station. From a structural point of view the cyanide started. The last roof truss was put in place on Nov. 4, and by Nov. 10, sheeting was finished so that the steel-tank erection could be commenced.

On Nov. 24 ventilators, windows and doors were in place and cornice and corrugated-iron work was completed. The time elapsed since starting on crusher-

TABLE 3. TOTAL CONSTRUCTION COSTS

Month	Direct Labor Cost	Total Cost
July	$165.02	$243.80
August	1,332.06	3,297.33
September	2,217.52	5,470.11
October	5,327.84	11,389.53
November	4,942.72	31,728.66
December	3,695.97	30,139.72
January	5,169.64	19,696.79
February	5,283.05	15,834.11
March	2,789.33	3,098.93
April	358.86	921.24
	$31,282.01	$121,820.22

station forms was 65 days. Time required to erect cyanide-plant and crusher-station buildings on completed foundations was 33 days. The cost of erecting these build-

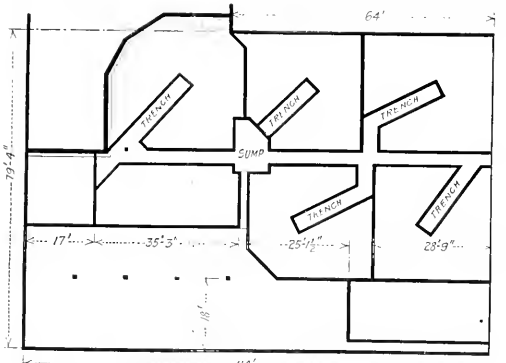
ings is shown on the table of summarized cost of the mill construction, but is repeated here with additional data.

TABLE 4. COST OF BUILDING ERECTION

	Board Measure, Ft.	Labor, $	Material, $	Total, $	Per Cent. Labor in Cost	Volume, Cu.Ft.	Cost per 1,000 Cu.Ft.
Crusher station	45,000	1,773 16	1,732.96	3,506.12	50 5	43,500	$80 00
Cyanide plant	192,000	4,624.97	4,815.65	9,440 62	49 0	257,000	36 00

The great difference in cost is due to the fact that the crusher station has two wooden floors above the basement, the upper one of which has to carry a heavy load. On this account center posts, beams and heavy joists are provided. Also the trussed conveyor bridge and the scalehouse addition (also trussed) are included in the crusher-station cost. As they involve a larger amount of material and labor in proportion to their volume than straight building construction, they have operated to raise the cost per unit of volume. Again, the ore bin comprises a larger proportion of the crusher station than does the ore bin in the cyanide plant.

While the work on the crusher station was just as efficiently done as in the larger buildings, as indicated by labor-material ratio, the figure $80 per 1,000 cu.ft. of volume will hardly have a wide application to other construc-



TANK-FOUNDATION PLAN AT TOUGH-OAKES MILL

tion operations, owing to the peculiar conditions at Tough-Oakes. On the other hand, the figure $36 per 1,000 cu.ft. is one which probably can be used as a basis for estimating on similar construction. The basic prices are: Lumber, $24 per M; galvanized iron, $3.50 per square; carpenters, $3.25 per 9-hr. day. Since labor and material are roughly half and half, any marked variation in either commodity can be easily allowed for in estimating. It is assumed, of course, that the lightest design consistent with strength and rigidity will be employed.

Small buildings cannot be estimated on the same basis as the more pretentious ones, as is shown by Table 5. These buildings are all of the balloon-frame type except the machine shop, which has a light truss of 6x6-in. lumber. Floors are double thickness, and all studs and rafters are 2x6 in. Buildings made of 2x4-in. material are found to depreciate rapidly after the first year.

TABLE 5. COST OF SMALL BUILDINGS

Building	Labor, $	Material, $	Total, $	Per Cent. Labor in Cost	Volume, Cu.Ft.	Cost per 1,000 Cu.Ft.
Transformer station	192 08	367.03	559.11	32	7,800	$72
Machine shop	259 02	404.91	723.93	36	12,500	58
Carpenter shop	198.83	355.82	554.65	35	8,000	69
Heating plant	265.45	358.30	623.75	42	9,800	64
Total	915.38	1,546.06	2,461.44	37	38,100	$65

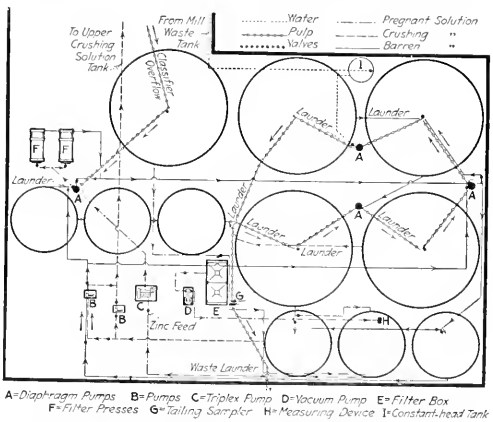
The percentage for labor is in all cases smaller than for the main buildings.

The erection of the steel tanks was begun on Nov. 12. The buildings were closed but not heated, and the weather continued mild. The complete list of tanks is shown in the accompanying table.

LIST OF TANKS IN CYANIDE PLANT

1—30x10-ft. steel tank with overflow ring.
4—28x10-ft. steel tanks with overflow ring.
3—16x12-ft. plain steel tanks.
3—16x10-ft. plain steel tanks.
1—20x10-ft. plain steel tank.

The total number of rivets came to 35,000, and the estimated weights varied from 140,010 lb. to 129,935, with different manufacturers. The price at which the contract was let called for the laying down of the material at Swastika station, 400 mi. north of Toronto at 3.13c. per lb., and erection an additional 1.5c. per lb. In this contract the purchaser was called upon to supply and erect such scaffolding as was necessary, as well as to provide compressed air for pneumatic tools. All tools, forges,



TANK ARRANGEMENT AT THE TOUGH-OAKES MILL

chain-blocks and labor of erection were provided by the contractor.

The complete cost of the tanks erected on the foundations amounted to 5.3c. per lb., made up as follows:

COST OF TANKS ERECTED

Tank material f.o.b. station	$4,390
Cartage to mill site	240
Riveting and erection contract	2,100
Power, labor and material, supplied by the company on erection contract	766
Total	$7,496

The erecting gang at first consisted of the boss erector and three men, using one riveter. It was soon found that progress was too slow and another four men, using another riveter and a calking machine, were added. These men subcontracted a portion of the work at the rate of 1⅛c. per rivet for ⅝ rivets, and 1¼c. per rivet for ½-in. rivets. On this character of work 600 rivets per day for a gang consisting of heater, riveter and bucker-up was found to be good work.

The bottoms of all tanks were calked on the inside and tested with about 4 in. of cold water. All joints are metal to metal, no tar paper or other filler being used. Any leak which showed over 1 drop in 20 sec. had to be remedied before the tank was accepted and lowered into position. The rivets in the side plates and the calking were passed on by inspection, as sufficient water for filling

a tank was not available. The bottom plates of the tank rest on 2x8-in. planks spaced 6 in. apart on packed-earth fill. The work was completed on Jan. 7, a total of 54 working days. A rectangular steel box with hopper bottom for holding clarifying-filter leaves was also erected during this period.

The tabulated construction costs are shown in Tables 1 and 2. Both direct labor and cost by months is shown in Table 3. Actual labor is slightly higher, owing to some distributed charges. Material was charged to mill construction on arrival at mill site. The total cost of the entire mill construction was $121,820.22, against an estimated cost of $124,840. Regular operations began Mar. 15, about two weeks ahead of the construction schedule at first adopted. No mechanical difficulties or other troubles were encountered, and the mill went smoothly into operation.

(To be concluded)

Mining Operations of the Granby Consolidated

For the year ending June 30, 1915, according to the company's annual report only recently published, the shipments from Phœnix and Grand Forks, B.C., amounted to 611,000 tons. The output from the Phœnix mines was curtailed considerably owing to the war. The mining cost was 85c. per ton of ore shipped, which was about 5c. higher per ton than the average for the previous five years. This was due partly to the shutdown last fall and the subsequent starting of operations in the winter, but it also reflects the increasing expense of extraction attending decreasing ore reserves. The reserve tonnage in these mines at the end of the fiscal year amounted to 4,232,405 tons.

From the Hidden Creek mine at Anyox, B. C., the shipments for the year amounted to 477,435 tons. The cost of mining per ton of ore shipped was $1.03. The ore reserve, which assayed 2.2% copper, was, at the end of the year, 9,205,837 tons. There was a further reserve of low-grade copper ore, averaging 0.63% copper, amounting to 8,628,000 tons.

At the Bonanza mine, about two miles up Bonanza Creek, south of the smeltery, nothing was done during the year either in the way of development or in preparation for shipping ore. The ore roughly blocked out by the work previously done on the property, averaging 2.6% copper, amounts to 414,775 tons. There is in addition 489,580 tons of low-grade ore that averages 0.7% copper. The company owns the Mamie and Dean mines on the Kasaan Peninsula of Prince of Wales Island, southeastern Alaska, and has an option to purchase the Ii mine adjoining the Dean. Work was resumed on these properties in April, 1915, after having been discontinued since the beginning of the European War.

Following the characteristics of the known copper mines in this vicinity, these mines are comparatively small. However, the results of the work on them has given sufficient encouragement to warrant the continuation of prospecting for, and seeking the extension and enlargement of, the known orebodies. From these mines there was shipped during the fiscal year 15,000 tons of ore averaging 1.5% copper. The reserve showings are 130,000 tons, with a fair prospect of developing treble this tonnage by future work.

At the Midas mine, Valdez, southwestern Alaska, work was started in April, 1915, to complete the aërial tramway, the mine terminal of this tramway, a few buildings at the mine, and to fill in about the pile foundation of the wharf shipping bins—to prevent destruction by teredos. This work is about completed, and with the little development work that has been done in the mine during the year, this property will be ready to make shipments as soon as arrangements are made for securing power to operate the air compressor.

The Origin of the Bingham Disseminated Ores

In a paper entitled "The Disseminated Copper Ores of Bingham Cañon, Utah," to be presented at the New York meeting of the A. I. M. E., February, 1916, by J. J. Beeson, the conclusions drawn as to the formation of the important sulphides in the disseminated ores are:

Pyrite, chalcopyrite, and probably a minor amount of bornite are the primary copper minerals. The primary sulphides do not occur in these ores as magmatic sulphides, but owe their present distribution to the magnetite which was a magmatic mineral.

Covellite is the most abundant secondary copper mineral, forming by a replacement of chalcopyrite in slightly acid to neutral solutions. Chalcocite is the most important secondary copper mineral, formed under slightly acid to alkaline conditions.

Secondary chalcopyrite may be an indeterminate mineral between pyrite and chalcocite, and bornite may be formed as an indeterminate product between chalcopyrite and chalcocite.

Secondary chalcopyrite and bornite may also be formed by the replacement of the copper in chalcocite, or covellite by the iron of the ferrous sulphate. The concentration of the ferrous sulphate in the descending solution is probably an important factor in secondary enrichment.

Le Pas District in Manitoba

TORONTO CORRESPONDENCE

The Le Pas mineral area in northern Manitoba which has lately attracted some attention is about 74 mi. north of Le Pas, commencing near the Manitoba-Saskatchewan boundary and extending eastward for about 125 mi. toward James Bay, and is about 50 mi. in width. The formation is Huronian, largely conglomerate and Keewatin schist and lies between limestone strata on the south and granite to the north. The deposits contain iron, zinc, copper, lead, gold and silver.

The most noteworthy discoveries have been made in a sulphide area about 25 mi. from Beaver Lake, the western extremity of the belt, where a surface outcrop of 1,000 by 200 ft. has so far been traced, the ores containing in addition to good gold and silver showings, zinc, lead, copper and iron. A large portion of this area has been staked by J. E. Hammill, W. J. Currie, Alexander Fasken and other prospectors. The Beaver Lake Mining Co.'s location is at the extreme west end of the belt, and 50 mi. east of the sulphide area. The Island Lake group of prospects have been located by Sam Otisse and M. J. Hackett. The new Hudson Bay Ry. will run close to the Le Pas mineral belt.

Notes on Shrinkage Stoping

By E. H. Dickenson and H. J. Volker*

SYNOPSIS—Details of methods for mining large deposits whose walls need support other than floor pillars and those whose walls need only floor pillars for support. At these mines under observation where rock was hard, speed of drilling with hammer drills was not equal to piston machines.

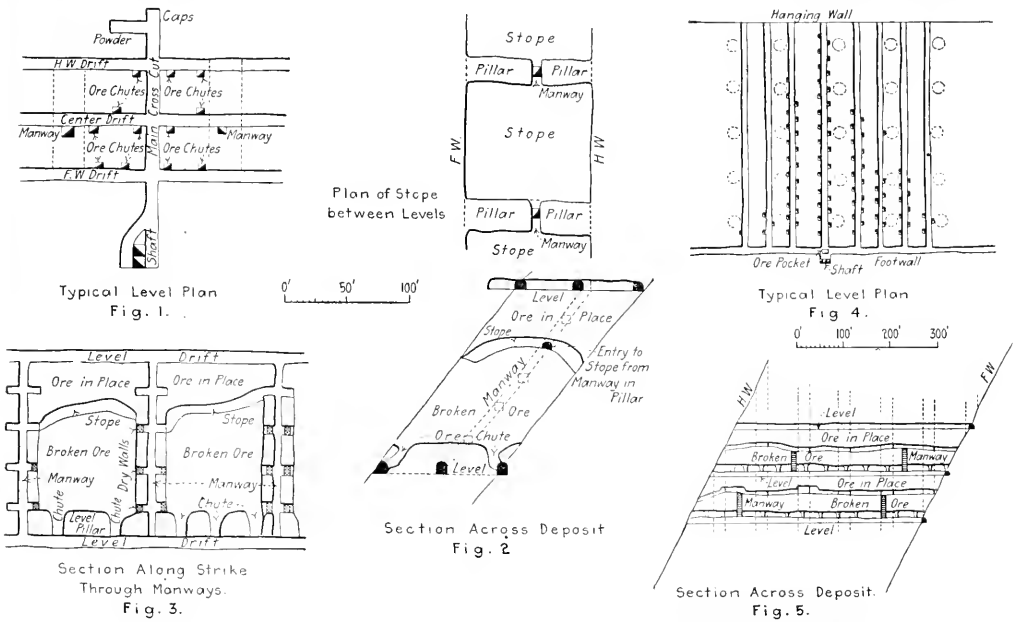
In shrinkage stoping the miner stands on the broken ore, enough of which is left in the stope to keep the back within easy reach of his machine. This means that after work is fairly started, only the excess in volume of broken ore over ore in place is drawn. The unavoidable accumulation of broken ore in the stope is one of the disadvantages of the system. Where the dip is sufficient, however, to permit a ready flow of the broken ore on the foot wall, where the wall rock does not slough off unduly and where the distribution of mineral is such that only negligible quantities of waste are likely to be mixed with the ore, the mining of the orebody may be accomplished by this method. While practically any width of deposit may be so attacked, deposits of the "narrow" vein type are not usually mined by this method, since such veins are often spotty and too high-grade to allow the broken ore to remain idle in the stope with economy. There is no physical reason why the method cannot be used even here. This article, however, has to do mainly with large low-grade deposits.

The dominating feature governing the details of the methods observed is the strength of the wall rock. A fair amount of strength of back is always essential. The haulageways may be run either across or along the orebody, but in each instance they must be close enough together to permit even drawing of the ore.

This discussion is divided into two parts: (A) Mining large deposits whose walls need support other than floor pillars. (B) Mining large deposits whose walls need only floor pillars for support. Only brief mention will be made of other types.

Development of Class A

Such a type may be represented by a deposit 100 ft. wide dipping at 50° and suited, both in grade and distribution of mineral, to be attacked by this method. Figs. 1 and 2 show a suitable arrangement of drifts, ore chutes and crosscuts in which the main haulageways are run parallel to the strike. The ore is drawn from the stopes into three drifts, which feed into a main crosscut and thence to the shaft. Ore chutes are put up about 20 ft. from the floor of the drift and are 15 to 30 ft. apart, depending on the ease with which the ore flows in the stopes. At intervals of 100 ft. along the center drift, raises are put up to the next level at the same inclination as the dip. These are used for manways, steel and timber passes and for ventilation. These manways are in the center of a pillar, rectangular in cross-section, which extends from foot to hanging and continues in



FIGS. 1 TO 5. SHRINKAGE STOPING METHODS FOR LARGE DEPOSITS BETWEEN WALLS NEEDING FLOOR PILLARS AND OTHER MEANS OF SUPPORT

*18 Lorne Apartments, Lorne Crescent, Montreal, P. Q.

depth with the mine workings. These pillars are the distinctive feature of this method of handling shrinkage stoping. They furnish the support needed by the walls and incidentally help support the back. They may be about 25 ft. thick. The manway in the pillar has drifts about 10 ft. long in either direction along the strike at intervals of about 30 ft. vertically. These give the men access to the stope as it ascends. A floor pillar of about 20 ft. is also left at each level. A longitudinal section through the center drift in the plane of the vein is shown in Fig. 3.

Another method of development for a deposit of this type is to carry the manways out through the back of the stope and have no raises in the pillars. This method gives better ventilation, but weakens the back and is usually less safe and convenient.

The distance apart of the levels depends upon many considerations. In one instance 150 ft. was the greatest distance that the vertical pillars would stand without crushing before the stope could be conveniently worked out. Sometimes leaving ore too long in the stope causes oxidation that may interfere with milling. Besides these, there are the more common influences that are discussed in any textbook on the subject. This completes the development of the class A type of deposit.

Development of Class B

This type will be represented by a deposit 500 ft. wide, dipping at 75° and similar to the previous deposit in all else except that its wall rock will stand only when supported by floor pillars. Figs. 4 and 5 show one arrangement of drifts, ore chutes and crosscuts. In this instance the haulageways are mainly across the strike. A hanging-wall drift may connect the crosscuts to facilitate haulage. The ore is drawn from the stopes into the crosscuts, thence to the main drift and ore pocket at the shaft station. The chutes are put up as before, 20 ft. above the floor. Pillars are left 85 ft. apart. They are vertical and cylindrical and center one under the other as the mine deepens, until they find the foot wall. In most of these, manways are put up from level to level with short drifts at intervals, to give access to the stope, but sometimes manways are formed by cribbing one of the ore passes. The latter is a cheaper method, but some manways must be maintained from level to level for ventilation. A floor pillar about 25 ft. thick is left as before. In this case special pillars are left for the support of the back, but only floor pillars support the walls. When such a stope is worked out and drawn, it has the appearance of an enormous colonnade 500 ft. wide and of indefinite length, the stope not having the dividing pillars of the first class.

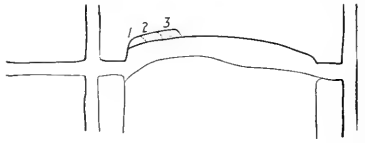
The distance apart of the levels in this case will depend more upon the decision of the mining economist than upon any physical reason, since the determining factor is the interest on the money value of the idle ore versus the cost of extra levels.

The two cases given may be considered briefly as to both wider and narrower deposits. No change occurs in either method as width increases. As width decreases, case A must maintain all its pillars, while as soon as the width is about 75 ft., there is no need of vertical pillars in case B. In narrower veins the floor pillars may disappear in either case, stulls or other timbering furnishing support for the broken ore.

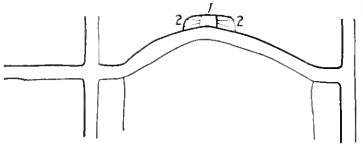
Stoping is started from a short drift either from the top of one of the ore chutes or from the end of the lowest drifts in the manways. This is wall-stoping and is carried on with piston machines. In the first example wall-stoping would be limited to the space outlined by the pillars and walls. In the second example any length could be opened up.

Having enlarged the stope to a suitable size, back-stoping is commenced. The quality of the back will again regulate the details of procedure. Assuming, in case A, a rather treacherous back with horizontal slips, it will be seen that working under overhanging ground would be dangerous. Fig. 6 represents a safe method of procedure. A cut is taken from foot to hanging across the deposit, and piston machines work away from this cut. A more rapid, but not quite so safe, method may be used, as in Fig. 7. The cut in this case is taken across the middle of the stope, and the machines work away in opposite directions. A third method to attack this particular kind of ground is to make a cut across the stope at each end and leave the stope until the intervening slab caves, plugger drills being then used to break it into smaller pieces.

It will be observed that the use of hammer drills is not advisable in a deposit of the peculiarities mentioned,



Side Cut.
Fig. 6.



Center Cut.
Fig. 7.

FIGS. 6 AND 7. METHODS OF BACK-STOPING

for with horizontal slips, vertical or even steeply inclined holes shatter the back and render it unfit to work under.

In class B, let us assume that there are no horizontal slips and that the ore stands well. Back-stoping may go on much less carefully. Any number of circular cuts can be made in the stope and machines work away from these points in circles; or the first two schemes given may be used. The stoper drill may be advantageously used drilling up into the overhanging ground. The drill runner, however, need not always stand directly under the overhang, though his machine may be working there.

The barring or "scaling" down in mines worked by this method is another point of great importance. In cases where the back is bad, it is wise to have the stope boss carefully inspect the stope before permitting the men to enter. In some cases a man is kept barring down all the time, and if the mine is not worked on Sundays, an especially careful inspection is made on that day, extension ladders being used at inaccessible points.

One of the most baffling problems to solve satisfactorily is that of chute gates. In mines of this class large boulders or slabs render the simple arc gate or the common double-sliding boards unsatisfactory.

Finger gates are successfully used in some mines. A bulldozing chute was described in the Oct. 18, 1913, issue of the *Journal*, and a chute using pole lagging for a gate was also recently described therein. All these are to cope with the large boulder problem. Of the three, the finger chute seems the most complicated mechanically. The bulldozing chute described by G. J. Jackson is very ingenious and, though requiring a lot of headroom, time and work to construct, it has but little to get out of order. It would seem, however, that if ore passes were numerous the expense of such a gate would be rather high. The chute of pole lagging is simple and cheap, but when this is used, it is difficult to prevent rushes of ore into the drift after a boulder has passed through. There are other schemes for handling large boulders in chutes, but those mentioned appear to be the most successful.

The foregoing discussion leaves little place for the stoper drill. Piston machines have been used to put up raises, and in one mine at least they are used to put up the ore passes. Piston machines use larger steel, making fewer holes necessary, and they can put in deeper holes. This is not intended to discount the ability of the hammer drill, but in very hard ground—in which most of the foregoing observations were made—the much-lauded speed of the hammer drill does not obtain.

Possible Source of Potash

Following Secretary Lane's instructions to put special effort into its potash investigations, the Geological Survey is publishing the suggestion that a possible source of potash may exist in the tailings piled up at the concentrating mills of the big copper mines in the West. The "porphyry" ores which are being mined by the millions of tons annually contain several times as much potash as copper, and this remains in the tailings at the mills, material already finely ground and in condition for treatment, as well as easily accessible for shipment. This potash, however, is locked up in the form of silicate minerals, and the commercial extraction of potash from silicates has been for several years the subject of earnest study by industrial chemists. If this problem can be solved, it would appear that a large tonnage of potash-bearing material is available in the Western states.

A brief report by the Geological Survey (Bulletin 620-J) contains typical analyses of these "porphyry" ores from the largest copper camps in a half-dozen states, as well as tonnage estimates of the ore reserves and ore already mined and treated. A few check analyses of tailings are also published.

Suggestion of a possible potash reserve in these tailings originated with B. S. Butler, the geologist in charge of the Survey's statistical study of copper, who has based this short paper upon the published analyses of specimens collected by the government geologists in their investigations of the mining districts.

The significant fact regarding this possible source of potash is that in quantity it is more than adequate to meet all the needs of the country as measured by presen consumption.

Plucking the Goose as Town Policy

To the average onlooker, who associates the terms "taxation and representation" somewhat vaguely with the Boston tea party and lets it go at that, there was nothing about the Harrison bill, recently defeated by a determined filibuster in the Minnesota Legislature, to catch his attention or warrant the fight it raised, says *The Survey*, Oct. 16, 1915. It is proposed to restrict tax levies for municipal purposes (exclusive of the support of schools) in towns of the third and fourth class, to $25 per capita. The average per capita rate throughout the state is about one-fifth of that amount.

In the background is a story of absentee ownership with a new problem on its hands, of charges and counter-charges of looting and oppression, in which the United States Steel Corporation and other mine owners appear as plaintiffs, and five towns on the Mesabi Iron Range in Minnesota play the rôle of hold-up men, of specialists in town improvement or of thrifty taxpayers holding rich corporations to proper account—all according to the point of view.

How Do Your Taxes Grow?

In 1914 the average per capita tax for local purposes in 140 Minnesota cities and villages was $5.35. In Duluth, St. Paul and Minneapolis, cities of the first class, the per capita taxes were $11.01, $11.20 and $12.52 respectively. The per capita tax in Hibbing was $85.35. Nor is Hibbing a millionaire colony. It is a mining village of some 10,000 population, the principal industry of which at present seems to be taxgathering.

During the past decade, the taxes have increased 27 times as fast as the population. And the story of Hibbing is in essentials the story also of Chisholm, Buhl, Keewatin and Mountain Iron.

The explanation is simple. The voters levy the taxes. The nonvoting mining corporations own about 98% of the taxable property. Somebody who wanted a new sidewalk or an extra town pump woke up to the possibilities of the situation. Soon the town pockets were bulging with gold, which seemed to burn the traditional holes in them. As the *Mesaba Ore*, of Hibbing, remarked editorially (Mar. 27):

> We should not overlook the opportunity presented to us, and you'll notice we are not overlooking it.

While Hibbing took a leading part, it did not play the game alone. For some years the five towns carried on rival village-improvement bees enlivened by an exhibit of how much open-handed communities can spend when money comes easily.

Hibbing Installs a Great White Way

Before long, Hibbing had more street lights on its "Great White Way" than Cincinnati, a city of 400,000. Eight ornamental lamp-posts, each carrying five incandescent lights, now illumine the principal street intersections. It spent $374,000 for paving in 1914. Its payroll for that year was roughly, $446,000, which provided for a monthly average of 894 men, although there were but 1,318 voters at the last state election. The only state officers that received a larger yearly income last year than Hibbing's treasurer were the governor and the justices of the supreme court.

The expenditure, in a single year (1914) was $1,204,742. Only $620,434 of the warrants issued for this were met with cash, and the outstanding current indebtedness at the end of the year amounted to $1,252,597.

Chisholm, which had 733 voters at the last election, had a monthly average of 538 men on her payroll. An attempt at economy on the part of some of the more timorous members of the council was scathingly dealt with in the *Tribune-Herald* of Mar. 26 last:

> By its action Wednesday the Chisholm council put a crimp in the local baseball team, many of the men that had been given jobs all winter in an effort to keep them here for the coming season being laid off. This is in striking contrast to the action of the Hibbing council, which this year has imported men from the best leagues possible in order that the village of Hibbing might have a first-class ball team.

After a defeat by one of the other towns, the council sought to remedy the error referred to by voting $1,000 to the team.

When a municipal well was sunk in Keewatin, it was a ceremonious occasion. It took five inspectors and a superintendent to supervise the work, in addition to a city engineer. The tax levies had been high for years, but took spectacular jumps in 1913 and 1914. Hibbing's rose gradually from $60,985 in 1904 to $276,490 in 1912, to $753,800 in 1914, and $1,693,933 in 1915. The levy in Mountain Iron for 1913 was 435% greater than the year before.

There was apparently no malice behind these increases —only an awakening to good business opportunities long neglected. And when the mining companies found their protests unavailing and sought legislative protection by the introduction of the Harrison bill previously referred to, indignation rose high in the five towns.

A Sacred Duty to Put On All Possible Taxes

Their main contentions were that they had a perfect right to levy extraordinarily large taxes on the mines, because the mines were exhausting the ore beds and would soon leave the towns with practically no taxable property; second, that the bill was a special-privilege bill fostered by big corporations in the interest of Eastern capitalists to the detriment of local communities; and third, that the expenses of government in mining towns are necessarily higher than in ordinary towns. As the *Mesaba Ore* put it:

> The "Ore" believes that every cent possible should be collected from the mining companies while they are with us, to the end that we may retain unto ourselves a share of the wealth that, once removed, will never return. . . . We do not believe in waste or extravagance in municipal management or anywhere else, but we shall hold that the village of Hibbing should collect every year the one and one-half million dollars due it from the mining companies.

And on Mar. 27 the same paper charged the city councils of the iron range with being

> remiss in their duty to the people of these communities because they do not levy the full amount allowed by law and spend it every year, whether it be extravagance or not. We owe it to ourselves to collect every cent available from the taxation of these mines and use it to beautify our towns because it belongs to us. Hibbing surely receives no thanks for handing over a million dollars a year of its own money to Eastern mine owners, and we will be just as well treated if we collect and spend all that is due us.

The mining companies in reply maintained that the ore deposits will not be exhausted for a long time to come, and such feverish taxation is therefore unnecessary; that if it were true that the ore would soon be exhausted, that fact in itself would be the best kind of a reason why the towns should not expend such vast sums in public improvements, because as soon as the mines were closed most of the population would leave the villages and there would be no one to enjoy the extensive public improvements provided.

The Harrison bill passed the Senate by a vote of 41 to 7, but was defeated in the House by a filibuster which lasted four weeks, although the bill had the support of most of the towns on the eastern end of the range. As the Virginia *Daily Enterprise* of Apr. 12 said, severely:

> If the "Mesaba Ore" (Hibbing) is of the opinion that its town has any considerable portion of the range behind it in the fight on the Harrison per capita tax bill it is mistaken. It has not. Hibbing is now in the position of the small boy who ate all the pie at the party. It has the bellyache and scant sympathy from the erstwhile guests.

Late dispatches state that almost all the mining companies have refused to pay their assessed taxes in Hibbing and will fight collection in the courts.

Basic Principles of Mining Cost*

I shall be able to call your attention to only a few simple matters, the influence of which on the cost of mining is, however, frequently overlooked even by experienced engineers.

The total cost of operating a mine can be divided into at least three independent items—labor, power and supplies. It is important to make this classification for two reasons: First, because the three items do not enter in the same proportions into the cost of operation at all mines; and second, because the variation in the cost for one item, from place to place, may not be in the same ratio as for another of the three items.

Geographical Situation Greatly Influences Costs

In general, the cost of mining in a given locality will vary with the expense and facilities for obtaining labor, power and supplies. Of all the mining regions in North America, I believe that the most favorably situated is found in western Pennsylvania. Between Pittsburgh and Lake Erie is a vast fertile country capable of supporting a large population; food is abundant, climate is excellent, and sociologic conditions are favorable. Hence labor is cheap and, what is of even greater advantage, can be carefully selected with a view to fitness. For power, the immense bituminous-coal fields and the areas yielding both oil and gas are close at hand. Finally, the district is surrounded and dotted with great manufacturing centers, whence mining supplies are available in great variety and at small expense of transportation.

When we seek to compare mining costs in so favorably situated a district with those prevailing in another part of the country—for example, Alaska or the desert parts of Nevada—strict allowance must be made for the changed environment. In both the localities just mentioned, and in many others as well, labor must be imported and it is not so easy to exercise discrimination in its selection. Furthermore, in a remote locality food is often poor and usually expensive and many of the ordinary comforts of civilized life, sometimes even the decencies, are wanting. These hardships must naturally be compensated in the form of higher wages. The cost of power is likewise gener-

*A lecture by J. R. Finlay before a class of mining-engineering students in the Columbia School of Mines, May 4, 1915, and published in the Columbia "School of Mines Quarterly" for April, 1915.

ally higher because of the expense for transportation of fuel. In some favored localities the supply of wood may suffice for a while, and in others hydro-electric power may be available, but the great majority of mines rely upon coal, and in many cases it will be found that the cost of transport exceeds that of mining. Thus coal which sells at Pittsburgh for, say, $1 per ton will cost $2.50 in the Lake Superior district, $4.50 in the Rocky Mountains and $7 or above in more remote districts. The same holds true of supplies, to the original price of which must be added cost of transportation by boat, rail, wagon or mule-back. Since steel and dynamite, the two most used materials, are relatively high-priced, the added cost of transportation is proportionately less than in the case of coal.

Situation Often Settles Payability

As a concrete example of the preceding remarks, let us compare a mine in southeast Missouri with one in Nevada, in both of which districts I have recently been so fortunate as to gain first-hand experience. In both cases we shall estimate that the output is at the rate of 4 tons per man per day. In southeast Missouri labor (at $2.60 per day) costs 65c. per ton of ore mined and milled; power (coal selling at $2.25 per ton) costs 25c. per ton of ore; and supplies cost 15c. per ton of ore; total, $1.05 per ton. Profit on this ore would then be about $1 per ton, out of which to deduct various general and interest charges. At a mine of the same character in Nevada, labor (at $4 per day) would cost $1; power (coal at $6.75 per ton), 75c.; supplies (estimated at 20% higher than in Missouri), 18c.; total, $1.93 per ton of ore, or $0.88 more than in Missouri. If the ore had the same market value, the profit would be only $0.12 as against $1, and this difference would very probably be the deciding factor in determining whether or not to begin operations in the more remote district. In short, the extreme variability of operating conditions at different mines and in different districts must never be overlooked.

It has been said that mining engineers do not know how to figure costs as a contractor would figure them. This is not exactly true, because all successful engineers really do know how to do it, and the wider their knowledge of operating factors the less liable they are to make mistakes. As a rule careless or ignorant computations result in underestimates. An excellent practice is for an engineer to put himself in the position of a contractor, personally responsible, for a loss; cost estimates then cease to be academic questions.

Overhead Must Not Be Disregarded

The most fertile source of mistake in cost estimates is to assume that the data relating to a short period, possibly during a stage of most advantageous operation, are a true average over the whole life of an undertaking. It should be remembered that the cost of an enterprise includes everything that has to be done, from start to finish. To illustrate, suppose a shaft has to be sunk in New York City. If a practical miner were asked how much it would cost, he would first inquire how hard the rock is, and would then figure the cost merely as a job of rock breaking, at so many feet per shift. A contractor, on the other hand, would include in his estimate the necessity for installing hoists, compressors, shops and headgear, entailing maintenance, depreciation and interest on the cost of equipment during the whole period of operation.

In comparing one mine with another, the physical characters of the ore deposits are no less important than their geographical situations, a feature of the problem that is sometimes carelessly overlooked by those who ought to know better, and often purposely disguised by those who have some nefarious purpose in view. How often have we heard promoters calmly assert that a gold-bearing vein in Georgia, for example, could be mined at the same cost per ton as at the Homestake or the Alaska Treadwell?

The importance of careful comparison of geologic conditions was forcibly impressed upon me about three years ago when I had occasion to examine a silver mine in New Mexico, at which the cost of mining and milling was $8 per ton. The mine was controlled by residents of the Lake Superior district, who, reasoning from their immediate experience, thought that the cost ought to be reduced to $3 per ton and wished to be informed why not. The reason is that a silver lode in New Mexico is not like a bed of copper rock or a basin of hematite in the Lake Superior region, and cannot be mined in the same way. Actually, the Camp Bird mine, of Colorado, offers a much clearer analogy, in width of vein, character of mineralization and occurrence of oreshoots, the latter constituting only 25 to 30% of the whole vein and compelling a relatively great amount of exploration and development. The cost of Camp Bird is from $7 to $8 per ton. My Lake Superior friends failed to be impressed by my reasoning and proceeded to capitalize and equip their mine on the assumption of $3 costs; they are now sorry they did so.

While a careless reasoning from analogy may lead to disastrous failure, as in the case just noted, on the other hand, if geologic conditions and working environment at a new locality be reasonably similar to those at an older and established mine, this fact offers a quick and serviceable means of estimating the probable working cost at the mine about to be developed. In fact, a simple comparison, provided that all conditions are closely parallel or provided that allowance is made for divergent conditions, is much more useful and accurate than any amount of independent figuring.

Hamilton Smith's Rule a Wise One

In this connection, it is often possible to make use of certain formulas and standards of comparison that are not so well known as they deserve to be. Hamilton Smith, a distinguished engineer about 30 years ago, suggested the advantage of comparing mines on the basis of yield per unit of stoping area, and gave as his opinion that, with gold ore of good quality, no mine would be profitable which yielded less than $3 per sq.ft. of stoping area, equivalent to $130,000 per acre. Applying this formula recently to a fairly profitable gold mine in Nevada, having a vein 1 ft. thick, of ore averaging $40 per ton, I was interested to observe, allowing 13 cu.ft. per ton, that the yield of that mine was almost exactly $3 per square foot of stoping area. Actual stoping width was about 4 ft., and profits were about 20% of the gross yield.

Smith's factor is important to bear in mind, regardless of other estimates of cost obtained by calculation, comparison or otherwise, especially for checking overestimates of net profits. A mine alleged to yield net profits of 75% of the gross output should be approached cautiously, because such mines are very rare. The Goldfield Consolidated, for example, for considerable periods

yields at the rate of $20 per sq.ft. of the whole area of vein explored—not merely shoot or stoped area; yet the net profits of this mine for the past five years have averaged only 58% of the gross yield, under particularly competent management. On the whole, Smith's rule is a wise one to follow.

Cost Per Ton Often No Criterion

Some people are inclined to attach too much importance to cost per ton, as though this unit possessed some sacred functions. It may often happen that some other unit, as Smith's yield per unit of stoping area, is more serviceable and relevant. Cost per ton is merely the value of the work that has been done on that ton and may bear a very indefinite relation to the profitableness of the operation. As an extreme case, 1 ton of gold worth $600,000 might be mined for $450,000, or 75% of its value, yielding a profit of $150,000. A ton of silver worth $15,000 is mined at Cobalt for $6,000, or at $600 per ton of ore, assuming it to contain 10% silver; yet, rightly considered, this should not be called expensive mining. At Grass Valley, Calif., it costs about $5 to mine and mill 1 ton of ore; at the Michigan copper mines it costs only $1.25; yet applying Smith's unit, we find that the cost per acre of stoping area is nearly alike in these two places—$100,000 at Grass Valley and $70,000 to $120,000 in the copper country. In southeast Missouri the cost is almost exactly $100,000 per acre for mining and milling. We thus see that the really important factor is not how many tons are mined, but how much area must be excavated.

Type of Orebody Influences Cost

Finally, before making comparisons of cost it is important to note the relative difficulties arising from different positions of an orebody; it makes a great difference whether a deposit is horizontal, vertical or inclined. A horizontal deposit is always the cheapest to mine, because when the shaft is sunk there is only one level, one shaft, one pump station. A vertical deposit requires many levels, each exploited separately, each requiring a shaft station and sometimes an independent pump station. Inclined deposits, if not steep enough for broken ore to slide, involve all the disadvantages of a vertical vein, with the added expense of handling ore in stopes.

Your professors have of course discussed the engineering aspects of this matter; I intended only, in conclusion, to emphasize the importance of careful scrutiny before attempting a comparison of working costs.

Anaconda's Community Experiment

One year has elapsed since the Anaconda Copper Mining Co. completed its plan for providing farm homes for its employees. In that time 40 families have established themselves at "Opportunity," the new community six miles east of Anaconda. Eighty children are attending the new Beaver Dam school in Opportunity. Street-car service meeting all shifts has been established, and for a 5c. fare the employees are carried to and from the Washoe Reduction Works at Anaconda.

By way of review it might be mentioned that this enterprise is an outgrowth of the smoke litigation of some years ago. At that time the territory embraced in the new community was practically a swamp. Profitable agriculture was impossible owing to increased wetness of these bottom lands from irrigation of higher lands. Originally the bottom of an old glacial lake, later a beaver-dam bottom where wild duck, muskrats and beaver made their homes, this land in its drier portions was supporting an indifferent agriculture where wire grass and slough grass were the principal crops and the prosecution of smoke claims the main occupation of the landholders.

WHEAT—FIRST CROP AFTER RECLAMATION—1915

BARLEY—FIRST CROP AFTER RECLAMATION—1915

No place in America in the same length of time has had a more revolutionary change take place than that which has been effected in this community—swamp and slough have been replaced by garden and grain field. Land that was so boggy that portions were fenced to prevent loss of livestock from miring is traversed daily by street cars and automobiles, while all over the area comfortable little homes are springing up, the nucleus of a better set of living conditions and a better citizenship.

About 4,000 acres of land has been reclaimed, of which 1,000 has been opened for settlement. This reclamation has been effected by tile drainage in which parallel lines of 12-in. tile have been placed 1,000 ft. apart along the line of greatest slope at a depth of 6 ft. The tough sod was then torn up with specially designed machinery, the peat burned off, and later plowed and disked with traction machinery. The land was laid off in tracts of from 5 to 10 acres, the majority being 10 acres. Every tract has a graded street in the front and an alley in the rear. The land is sold by direct purchase or on a bank-installment plan over a 30-month period and is turned over to the purchaser plowed and ready for crop. An irrigation system has been provided by which water is delivered at the owner's tract. The source of the

irrigation water is the creek flowing through the land, supplemented by the novel arrangement of pumping drainage water from sumps in the drain lines, the power line for pumping plants also supplies power for domestic lighting, pumping and cooking.

Reclaimed swamp land must of necessity be cropped for several years before becoming suitable to seed to permanent hay or meadow crops. The Farms Co., after the first tillage, plows, seeds and harvests the grain crops for the tract owners, charging them the actual cost of these operations. This obviates the necessity of landholders' owning tillage machinery and horses sufficient for the work, which would be impractical on such small areas. As an aid to their building operations, the lumber department of the company provides lumber at cost plus a small handling charge, and several carloads of lumber are kept in stock on the ground.

Many owners whose means are limited have built temporary houses which will be converted into barns or chicken houses when more costly homes can be afforded. In this connection the company has made arrangements

RESIDENCE AT OPPORTUNITY

EXHIBIT AT THE OPPORTUNITY FAIR

whereby land purchasers having their tracts paid for can secure a liberal loan on easy terms to help with their building operations.

Plans looking toward the development of the interest both of the parents and children in their homes and the enterprise are being worked out. A most successful agricultural exhibit and fair was held by Opportunity residents in the school building Oct. 9 and 10. The interest shown by the children was an inspiration and the exhibits a revelation even to the company officers who had shared in this development. Despite a heavy snow and rain, between 500 and 600 persons came to the little fair on Oct. 10. Next year greater things are promised—a school-garden competition for the children, a pig club and a sheep club and a bigger "Opportunity" fair. This year one tract owner showed 23 kinds of vegetables. Cows, pigs, chickens, turkeys, duck, geese and rabbits were shown. The best part of the fair, however, was the interest shown by the children.

Centrally located in the enterprise is a 65-acre park through which a clear, wooded mountain stream flows. The schoolhouse is in the park and the Anaconda Country Club is now building a clubhouse on a tract adjacent to the park, and a golf course has already been laid out.

With the Forty-Niners

The historically important discovery of gold in California was made in January, 1848, at John Sutter's mill on the South Fork of the American River near Coloma, a point only 10 or 15 mi. southeast of the town of Auburn. From 1850 to 1853 the greatest yield was derived from the gravels, and the largest annual output for this period was more than $65,000,000, in 1852. There was some reaction in 1854, due to previous wild speculation, but a production of about $50,000,000 a year, chiefly from placer mines, was maintained up to 1861, according to the United States Geological Survey.

At first the gold was won chiefly from the gravels along the present streams. Those who first got possession of the rich bars on American, Yuba, Feather, and Stanislaus Rivers and some of the smaller streams in the heart of the gold region made at times from $1,000 to $5,000 a day. In 1848 $500 to $700 a day was not unusual luck; but on the other hand, the income of the great majority of miners was far less than that of men who seriously devoted themselves to trade or even to common labor.

The gold pan, the "rocker," the "tom," the sluice, and the hydraulic "giant" or "monitor," named in the order of increasing efficiency, were the tools successively used by the miners. Into the "rocker" and the "tom" the miner shoveled gravel or "dirt," rocking the machine as he poured in water and catching the gold, often with the aid of quicksilver, on riffles set across the bottom of his box. Sometimes a stream was diverted into a flume to lay bare the gravel in its bed so that the miner could get at it. In sluicing, the gravel was shoveled into a similar but much longer box, through which a stream of water was allowed to run. The hydraulic giant was employed to wash into long riffle-set sluices immense quantities of gravel, especially from the higher (Tertiary) deposits, much of which was too lean to work out by hand. Water was brought for many miles in ditches and flumes from the high Sierra and conducted under great head to a nozzle, from which it was projected with tremendous force against the gravel. It was the vast quantity of refuse washed into the streams by these hydraulic operations that brought about the conflict between mining and agricultural interests finally decided in favor of the farmers.

Details of Practical Mining

Table Showing Minimum Grade of Copper Ore and Profits

By Frederick W. Foote

The accompanying table has been found useful in determining the lowest-grade copper ore that can be mined at a profit at any property. If the property is a copper producer only, the total cost of mining, milling, smelting, etc., is plotted on the table as a "deadline" above which no profit can be made. Of course lower grades can be mined with higher prices of copper. This causes the line to be jagged. Below the deadline, successive lines are drawn showing the range of percentages and prices in which the indicated profits are made. If any gold or silver is present, its value is taken from the cost of mining, so

TABLE GIVING PERCENTAGE OF COPPER AND VALUE PER TON OF ORE AT DIFFERENT PRICES *

10.0	200	26.00	28.00	30.00	32.00	

* Deadline with assumed production cost of $4 per ton of ore.

that the deadline is raised an amount equal to the aggregate value of the gold and silver. The table given covers the usual range of percentages and prices, but a table of this type can be made to suit the individual requirements of any mine. If preferred, the gold and silver credits can be shown separately, but it seems to me to be simpler to conceive of these credits as being applied to the cost of mining rather than to the ultimate profit.

In a particular case the cost of mining, etc., was $4 per ton. This caused the deadline to be as shown by the double line. If, for instance, $2.50 profit be required per ton and copper is at 15c., then coming along inside of the 2.50 block to the nearest approximation of desired value and going horizontally to the left, it is seen that 2.2% is the minimum ore minable.

An Electric Dragline Excavates 60,000 Yd. in 18 Days

Fast work was done by the operators of a 1¼-yd. electric dragline excavator on the drainage work of the Boise project, under way by the Reclamation Service. The *Reclamation Record* for October publishes the following data furnished by J. L. Burkholder, assistant engineer:

The machine was operated from noon on Aug. 14 continuously to the end of the month, and approximately three-quarters of the length excavated was in hard material which had to be blasted, 600 lb. of dynamite being used during the period. The dirt was moved at an average rate of two buckets per minute, or 2.3 cu.yd. per min. Counting the time actually spent in digging, the rate was 3 yd. per min.

RECORD ON 1¼-YD. ELECTRIC DRAGLINE

Operator	Amount Excavated Lin.Ft.	Cu.Yd.	Average Number of Cubic Yards Excavated Per Hr.	Per Shift

Blasting	0:45	0.2
Total	424:00	100.0

There were 49¼ shifts. The record run per shift was 1,583 cu.yd.

The Use and Abuse of Fuse

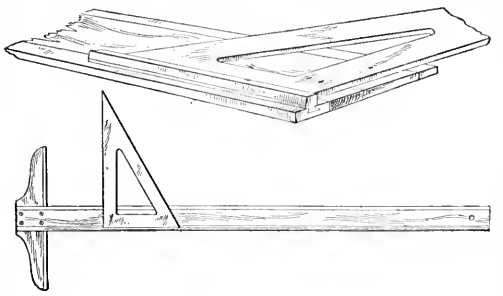
Many miners, acting in good faith but through a misconception of the waterproofing quality of axle grease or crude oil when applied to the outside of a capped fuse so as to make a so-called waterproof joint, start trouble for themselves. Grease and oil are solvents of the fuse varnishes, and when they penetrate the outer covering they destroy the powder train in the fuse with as great, if not greater, rapidity than would the water that the miner is trying to exclude.

When preparing fuse for use, it is common practice to coil it around the arm like coiling up a clothesline. This is bad practice because kinks are liable to occur to break the powder train. When cutting off the fuse care should be exercised to cut square across and not obliquely, which will leave a sharp point at the end of a fuse—not a particularly safe thing to jab into a blasting cap. Furthermore, if the point happens to be soft, as it is likely to be in warm weather, it will bend over or curl up and is liable to cause a misfire. Misfires are more likely to be due to lack of care on the part of the miner making up the primers than to fault in the fuse itself.

When making up primers, do not hesitate to cut an inch of fuse from the end of the coil. In doing this the damp ends will be prevented from getting into the detonating cap. Fuse that has been hammered or injured by falling ground, or damaged from any other source, should never be used. Any change in the covering of the fuse will either increase the burning rate or have the opposite effect and cause a misfire.

T-Square for Inking Over Fresh Lines

A T-square with three working edges on the bar has recently been patented by E. R. Ruehle & Co., 119 Fulton St., New York City. The third edge is furnished by a stop along the bar. By means of this addition the draftsman's triangle can be slid along the board, but held clear of the tracing, so that additional ink lines can be placed on a drawing without waiting for any fresh lines beneath to dry.



T-SQUARE FOR INKING OVER FRESH LINES

Diameter of Sheaves for Hoisting Rope*

The figures take care of the variables of depth of shaft, hoisting speed and acceleration stresses. The question of bending stresses is not considered. The bending stress of course increases as the diameter of the sheave or drum decreases. It could be kept from becoming too great by specifying minimum permissible ratios between sheave and rope diameters. The increase in stress caused by running a rope over too small a sheave is unimportant compared with the resulting increase in rope wear, and considerations of economy can be trusted to prevent the use of sheaves and drums too small for the ropes.

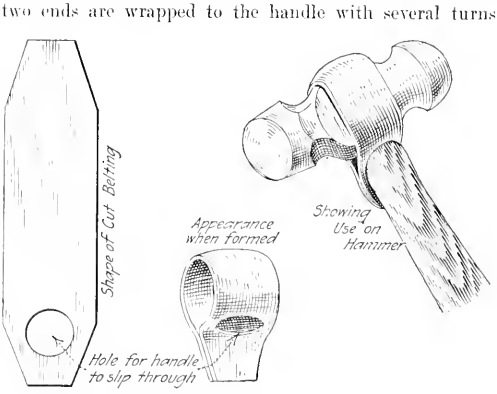
The economical ratio between rope and sheave diameters varies with the character of the wire in the rope and the type of construction. A pliable rope can run economically and safely over a smaller sheave than can a stiffer rope. The committee has reports of excellent results from the use of a 1¼-in. rope over an 84-in. sheave, which gives a ratio of 66, whereas in many cases, especially in the case of deep shafts and long ropes which usually are of necessity stiffer, a ratio of 100 has been recognized as not too high.

In connection with the question of sheave diameters, one point should be noted, namely, that it is possible to make the ratio too high under certain conditions, or more correctly stated, it is possible to make the sheave too heavy. This is the case frequently with turn-sheaves, guide pulleys, rollers, etc., on which the arc of contact and the compression between sheave and rope may be so little as to allow excessive slip, the rope failing to rotate the sheave easily. Of course such a condition would cause wear and tend to deteriorate the rope faster than would the use of a smaller, lighter sheave. To decide on a suitable size of sheave under such conditions the following rule is serviceable: Suppose that a ratio between sheave and rope diameters of 72 is considered permissible. Then when the deflection angle of the rope is less than 90°, that is, when it has less than 90° of contact arc on the sheave, the diameter of the sheave shall be eight-tenths of the deflection angle times the diameter of the rope. Thus as the deflection angle or arc of contact becomes less, the size of the sheave decreases. For a 45°-deflection angle a 3-ft. sheave is required for a 1-in. rope, and for zero degree no sheave is required, a rubbing board alone being sufficient.

*Abstract from "Rules and Regulations for Metal Mines," by Ingalls, Douglas, Finlay, Channing and Hammond; Bulletin 75, United States Geological Survey.

A Handy Soft Hammer*

A way in which to make an ordinary engineer's hammer serve in place of a mallet or wooden hammer for use on wood or other soft materials consists in using a piece of leather or belting in the manner shown in the drawing. A hole is cut in the leather large enough to be slipped over the handle of the hammer and then brought to the head of the hammer. The flap is then brought over the head of the hammer and nailed on to the handle, or the two ends are wrapped to the handle with several turns of fine wire. The hammer is used sidewise on wood, which brings the leather belting into play and softens the blow. In this way the user has a hammer ready for various uses in a very compact and convenient form. The leather will wear for a remarkably long time.



ENGINEER'S HAMMER WITH LEATHER CUSHIONING

*A. P. Connor, Washington, D. C., in "American Machinist."

P. & B. Paint for Spitting Fuses

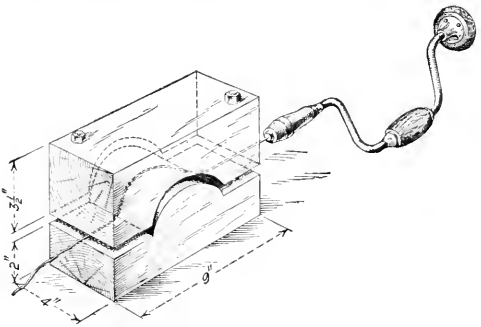
Many expedients are resorted to in order to insure the ignition of the powder train in fuse. Splitting the end of the fuse and inserting a pinch of dynamite or powder or a piece of candle wicking, and securing a stub of a candle to the end are schemes familiar to most miners, but

perhaps one of the best methods is that in use at the United Verde mines at Jerome, Ariz.

There the fuses, after being cut to the desired length, are dipped into P. & B. paint; one end only. The bunches of fuses are then laid up to allow the paint to harden. On application of a flame the ignition of the paint is instantaneous and is sure to fire the powder train. The paint will not drop off, as so frequently happens when using other attached means to fire the fuse, and the method has still another advantage in that the paint is waterproof and effectually guards the powder train from moisture, from the time the fuse is cut until it is set afire.

A Handy Wire Straightener*

One is sometimes confronted with the apparently hopeless task of straightening an old, crooked, kinked wire. To many this is no easy job, but to those that become



WIRE STRAIGHTENER IN OPERATION

familiar with the straightener here described the problem will be a comparatively simple one.

To make this straightener first procure two blocks of hardwood, each about 3½x4x9 in. Cut the two ends of one piece down from 3½ in. to 2 in. in thickness for a distance of 2½ in. from each end. This will leave a rectangular projection in the center of the piece. Round the two ends of this projection off as shown in the accompanying illustration. Now from the other block and on a 4x9-in. face cut out a concave depression to fit over the curved surface of the other block. Now, placing the two blocks together, bore two holes, one in each end and in opposite corners, as shown in the diagram.

By means of two bolts clamp the two blocks onto the wire to be straightened, near one end. Fastening a brace or something similar to the short end, turn the wire, drawing it through the block at the same time. The result will be a straight wire. This device will straighten a wire of any diameter.

Utilization of Peat Powder†

If peat that has been taken from the bog and allowed to disintegrate by lying on the surface of the bog during the winter be gathered, dried artificially and pulverized, a dark-colored nonabsorbent powder will result. The name "peat powder" has been applied to this product. It may be used in very much the same way that sawdust and powdered coal have been used.

When this powder is burned in specially constructed burners using a blast of air, it acts very much like a gas, on account of the intimate mixture that may be obtained, of powdered peat and air. The air supply can be regulated so as to approach that theoretically required for perfect combustion, and complete smokeless combustion results. The temperature of the flame is easily regulated, and temperatures sufficiently great for melting brass, iron and steel, and for other metallurgical operations, can be obtained.

Feeding Mine Animals

The one thing about a mine of which the superintendent knows less than any other is the proper care of livestock. Sometimes the entire mining proposition is dependent upon this livestock, and in many cases where no such vital importance attaches, great inconveniences and unusual expenses are caused by failure of the stock at some critical time. Furthermore, stock is expensive and forage is almost always unusually so in mining camps. Wasteful feeding is almost universal because it is generally left to some mule-skinner, who, if he has any idea of stock at all, has a very exaggerated idea of his own knowledge of the same.

The proper daily allowance of forage for a horse is 12 lb. of grain and 14 lb. of hay. If a horse weighs over 1,300 lb., however, he should be fed 14 lb. of grain and 17 lb. of hay per day. For a mule 9 lb. of grain and 14 lb. of hay should be allowed.

These allowances are prescribed for United States Army animals, but it is not deemed necessary to feed all animals the full allowance of grain. Each animal should be watched while eating and should be fed accordingly, except that the full allowance of hay should always be fed; if it is of good quality and the animal is in good condition, it will always be eaten. Grain should never be fed to animals when they are tired, hot or excited. If an animal continually fails to eat all of his allowance of grain, it should be cut down unless he shows signs of losing flesh; in that case he should be carefully watched and his mouth examined for lampas, and if he is found to be suffering from that cause, his grain should be soaked in warm water until soft. When changing grain, as from oats to barley or corn, cut down the portion of forage allowance, returning gradually to full feed in about five days. During this period more hay should be fed.

All animals need salt. The Army allowance provides for 2 oz. per week per animal, which is sufficient to allow a handful to each animal every 10 days. It is better, however, to feed salt a certain day each week.

Grain should always be fed before feeding hay. A mule will eat musty grain and hay, but a horse will not, and care should be exercised not to feed musty forage to either.

Mules give an indication that they are very tired when they fail to flap their ears while pulling a load. It may be relied upon that mules pulling a load and constantly flopping their ears, are in good condition.

Proper grooming of the animals every day will do much to keep them in condition and increase their pulling capacity.

*W. C. Eyl, University of Kentucky, Lexington, Ky., in "Coal Age," Nov. 6, 1915.

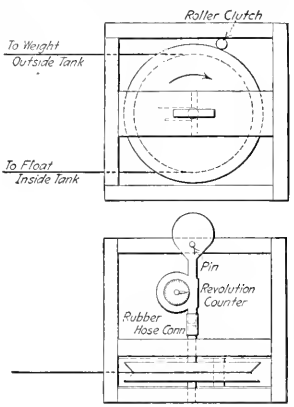
Details of Milling and Smelting

The Shapley Solution Meter

By Cooper Shapley*

In zinc-dust precipitation it is customary to use two gold sump tanks, one filling while the other is discharging. For measuring solutions under these conditions a meter must be used on each tank. The accompanying drawing shows one that is easy to make and has advantages of simplicity and accuracy.

Over the grooved wheel passes a light cord (fishline) to which a float is attached at one end and a light weight at the other. To the axle of this wheel is attached a revolution counter which registers the number of turns. The grooved wheel can move only in the direction of the arrow because of the roller clutch, which tends to wedge itself between the upright and the wheel when it tries to revolve in the reverse direction. When the solution in the tank is rising, the cord slips over the wheel and nothing is registered on the counter, but as soon as the level of the solution begins to fall, the wheel is turned in the direction of the arrow and the revolutions are registered. Each revolution represents so many tons of solution. It is an easy matter to calibrate the instrument, and as revolution counters usually register up to 5,000, it can be run for a month or several months at a time. In my case the wheel is 7½ in. in diameter and each revolution means 11.63 tons of solution. The float should be protected from ripples, since the slight up-and-down motion will cause the instrument to register too high.



SKETCH OF SOLUTION METER

*Mining engineer, Buckhorn Mines Co., Buckhorn, Nev.

Dolomite and Slag Furnace Lining

Owing to the present scarcity of magnesite brick, it may be of interest to some of the nonferrous metallurgists to try experimenting with a furnace lining recently patented by Albert P. Meyer (U. S. Pat. 1,160,085, assigned to the A. S. Davison Co., Pittsburgh, Penn.).

This consists of a uniform and intimate mixture of granules of basic slag and dolomitic lime, usually about 90 parts of lime and 10 parts of slag. Preferably a hard, compact, dense variety of dolomitic limestone should be used, and preferably those varieties high in magnesia. The limestone should be burnt to a degree sufficient to afford a sintered, clinkered or semi-fused mass, the material being thus prepared under conditions analogous to those of cement-clinker making, but with a higher finishing temperature; that is, around 2,800° F. The crude sintered granules of this lime are then mixed with granulated basic slag, in which state the material is either stored or shipped until wanted for use.

Effect of Sulphur Dioxide on Human Beings*

A careful consideration of all of the data concerning the occurrence of sulphur dioxide in the atmosphere in the Selby smoke zone and other places establishes the conclusion that the Selby smeltery, by the emission into the atmosphere of sulphur dioxide from its plant, does not maintain a nuisance in the southern portion of Solano County, California, as referred to an objectionable odor or disturbing physiological effects upon the mucous-membrane linings of the throat and lungs of human beings and domestic animals.

In order to determine the extent to which the invisible part of the Selby smoke may become a nuisance through the physiological effect its content of sulphur dioxide exerts upon man by disturbance of the normal functioning of the respiratory organs or disagreeably affecting the olfactory organs, the commission undertook an investigation to determine the sensitiveness of various persons to sulphur dioxide. It has already been shown that sulphur dioxide is the only gas discharged into the atmosphere through the stacks of the Selby smeltery that has an odor or can possibly be present in sufficient amount to produce any effect upon the throat and lungs when it is diluted by the air into which the smoke is discharged.

In the conduct of this investigation 60 subjects were experimented with. Some of them were observed through more than one experiment, so that a total of 85 experiments were recorded. Thirty-two of the subjects were persons thoroughly familiar with the odor and general characteristics of sulphur dioxide, and 28 were only sufficiently familiar with the gas to be able to identify it as "like sulphur matches when they burn," or by some similar method of comparison. Those thoroughly familiar with the gas were technically trained men or men that had worked in plants where sulphur dioxide is generated or is used; they were for the most part chemists, engineers and smelters. Those who were unfamiliar with the gas were the average intelligent citizens, sometimes capable of accurate description of the sensations they experienced under the tests and sometimes not; they knew the gas only as something that had a "sulphur smell."

Sulphur dioxide (SO_2) is a colorless gas of characteristic pungent odor and acid taste. It is 2.21 times as heavy as air, but mixes readily with it in all proportions

*Excerpt from "Report of the Selby Smelter Commission," Bull. 98, United States Bureau of Mines.

and once mixed does not, contrary to popular belief, again separate. In its concentrated form it produces marked physiological disturbances in all animal and vegetable organisms with which it comes in contact. It dissolves to a limited extent in water and has the property of combining with oxygen under proper conditions to form sulphur trioxide (SO_3). Sulphur trioxide combines very readily with water to form sulphuric acid.

Of those subjects who were acquainted with the gas and were trained to observe and report their observations correctly, none could detect the presence of the gas when it was breathed in concentrations of one part SO_2 per million parts of air. When the concentration reached two parts SO_2 per million, 13 of these subjects suspected the presence of something foreign in the air being breathed, but could not identify the substance, while two of the 32 thought they could identify the presence of the gas by their sense of taste, although they could not smell it. With three parts SO_2 per million in the atmosphere they were breathing, 26 of the subjects identified an acid gas as being present and six could detect nothing other than a foreign substance in the atmosphere. Of the 26 who could detect an acid gas, 21 identified it with more or less positiveness as sulphur dioxide, while five were doubtful of its identity. At four parts SO_2 per million parts of air, all but two of the 32 subjects were able to detect and positively identify the gas as sulphur dioxide. The two exceptions were men who had become more or less immune to the action of the gas from working in smelteries where the concentration is at times very high. At five parts SO_2 per million parts of air, all subjects but one, who was especially insensitive, were able to detect the gas. At eight parts SO_2 per million, all subjects except the same one could identify the gas as sulphur dioxide.

This would seem to indicate that persons who are thoroughly acquainted with the properties of sulphur dioxide, through study of, or experience with, the gas itself, can usually detect its presence in the atmosphere and identify the gas either by the sense of taste or smell when its concentration is about four parts per million or more. Approximately three-fourths of such persons are able to detect and identify the gas when its concentration is three parts per million, while about 40 per cent. are conscious that a foreign substance is in the atmosphere when the concentration is two parts SO_2 per million or more. In concentrations of less than two parts SO_2 per million, even persons thoroughly familiar with the properties of sulphur dioxide are unable to detect the presence of any foreign substance either by the sense of smell or the sense of taste.

Of those subjects who were unacquainted with the properties of sulphur dioxide, none could detect anything in an atmosphere containing one part SO_2 per million parts of air. This agrees with the observations of the "trained" subjects. At a concentration of two parts SO_2 per million, two of these persons detected a foreign smell in the atmosphere they were breathing but could not describe it. With three parts SO_2 per million, four subjects "smelled something" and six smelled "burning sulphur," while 18 "didn't smell anything." When the atmosphere contained four parts SO_2 per million, 10 of the "untrained" subjects smelled "burning sulphur," four "smelled something," and 14 did not note any sensation different from that experienced in breathing the ordinary air. With a concentration of five parts SO_2 per million, all of the "untrained" subjects except six "smelled something" or "smelled burning sulphur." At 12 parts SO_2 per million, all of the subjects could identify the gas as that of burning sulphur.

This would seem to indicate that the average citizen, not technically trained, can usually detect the presence of sulphur dioxide in the atmosphere and can identify it either by sense of taste or smell when its concentration is five parts SO_2 per million parts of air or more. One-half of such persons are able to detect the presence of the gas and some of them can identify it, when the atmosphere contains four parts SO_2 per million. When the atmosphere contains three parts SO_2 per million, 65 per cent. of the average citizens fail to record any unusual sensations when breathing it, whereas only 217 persons in every thousand would experience the feeling of breathing an atmosphere contaminated with "smell of burning sulphur." When the concentration is two parts SO_2 per million, only the most sensitive, 71 in every thousand, can detect a foreign odor; and below that concentration none can detect any foreign odor whatever.

Consideration of the data from all points of view indicates that a proper conclusion will be drawn from this investigation if it is stated that the average citizen is conscious of pollution of the atmosphere by sulphur dioxide when its concentration is approximately 3.5 parts per million parts of air; and the "trained" person is conscious of such pollution when the concentration is approximately 2.5 parts SO_2 per million parts of air.

In order to positively establish the minimum concentration of sulphur dioxide that would be considered a nuisance to all persons, it would be necessary to experiment with a much larger number of subjects. The time at the disposal of the commission did not permit of this. It was found as a result of the work done in this direction that the elements of psychology and personal idiosyncrasy entered into the matter to a great extent. The symptoms recorded by the various subjects, both "trained" and "untrained," were very dissimilar. No agreement was found between the ideas expressed as to what concentration was a nuisance. Without exception, however, all subjects considered that the point of concentration at which they could just detect a foreign substance or at which they were just conscious that there was something foreign in the atmosphere, was not a nuisance.

The commission is of the opinion, therefore, that in order that the smoke from the Selby smeltery shall produce a nuisance in the smoke zone, sulphur dioxide must be discharged from the smeltery in such an amount that as the smoke blows over the smoke zone, the concentration of sulphur dioxide in the atmosphere of the smoke zone must be three parts per million or more. This figure is the mean of those recorded from the "trained" and "untrained" subjects and refers solely to a nuisance brought about by the presence of a disagreeable or offensive odor. The difference between trained and untrained observers in susceptibility to the gas is extremely interesting.

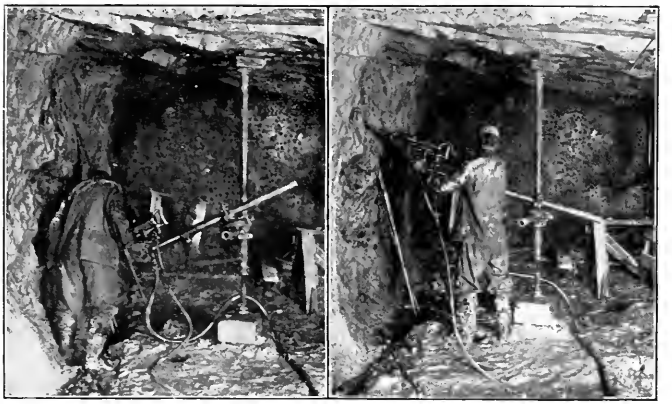
At the Mill of the Bunker Hill & Sullivan Mining and Concentrating Co., at Kellogg, Idaho, an Ottumwa box-car loader is used in an original way. The coarse jig concentrates are shipped in box cars, and it is found convenient to deliver them through a chute to the box-car loader, which expeditiously and satisfactorily loads them into the cars. The method is said to be very much quicker and cheaper than hand labor, and no fault is found with it.

Mining & Metallurgical Machinery

Sullivan Air-Feed Drifter

The Sullivan Machinery Co. is putting on the market an air-feed drifter that combines the advantages of the elimination of one man from the drilling crew, the introduction of hammer drills, the employment of a water jet, and the air feed, which eliminates the feed screw and shell of the old piston type.

The pneumatic feed mounting consists of a saddle on the outside end of a short arm attached at right angles to a piston rod 24 in. long. The rear end of this rod terminates in a piston that runs in a feed cylinder; the



SULLIVAN AIR-FEED DRIFTER AT WORK

combination being similar to that employed in reverse-feed stoping drills. The feed cylinder is clamped at any point desired in a hinged trunnion cradle that can be quickly loosened or tightened by means of one nut. The arm that supports the drill contains an air inlet with swivel elbow and a throttle valve by means of which air is admitted to both the drill and the pneumatic feed. This throttle has several definite positions, in each of which a different effect is secured. In one position of the throttle the drill and steel are carried forward against the rock by air admitted only through the rear end of the piston; in a second position the drill is started running; two other successive positions of the throttle bring the drill up to full speed; and in still another position air is exhausted from the rear of the feed cylinder and admitted to the front side of the piston head, thus carrying the drill and steel back out of the hole and away from their work. By simply turning the throttle the operator may thus throw the drill forward or back with perfect ease and in a remarkably short time. The advantages of such a device over the crank and feed-screw type are obvious. With this air feed, drill steel can be changed in as little as 30 sec., there being no chuck bolts to loosen and retighten, and steels of uniform length in sets are not necessary.

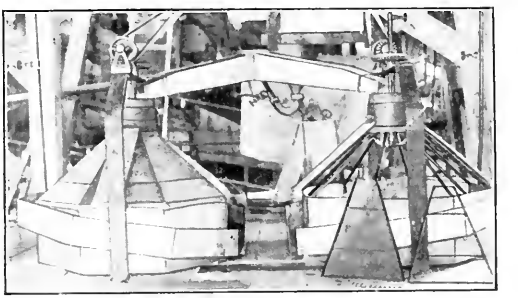
Should the drill steel show a tendency to stick while running, the operator, by setting a hand-brake on the throttle that throws on the reverse feed, can back the drill out of the difficulty with the hammer still running and the steel rotating. By simply turning the throttle valve, the drill may be made to alternately cut forward and retract itself, thus keeping the steel free and the hole round until the difficulty is passed.

With this drilling outfit, steels of a uniform length are not necessary.

The standard column for the air-feed drifter is 2½ in. in diameter, and arms can be used on this column up to 36 in. in length, so that it is entirely possible and practicable to drill a face 8 ft. high by 7 ft. wide, from one setting of the column.

The Wood Screening Machine

Machines for screen-sizing mill pulps have been in use for years, but the number of new ones that continue to appear indicates some difficulty in finding a perfect one. The device illustrated here is one designed to avoid, as far as possible, the inconveniences of the ordinary screening machines. It was designed by J. C. Wood, superintendent of the Hecla mill, near Wallace, Idaho, and is in use in that



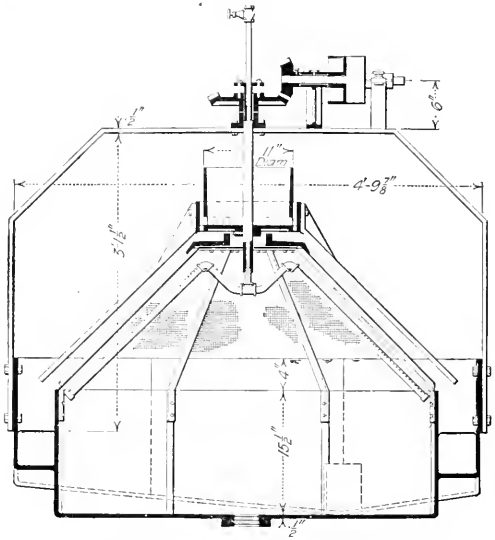
WOOD SCREENS, WITH FRAMES AND WITHOUT

plant. Mr. Wood has protected his machine by United States patent.

The Wood screen is in shape an octagonal cone, the eight sides of which are formed by steel frames carrying screen cloth of the desired mesh. Pulp for screening is delivered to the outside of the screens through an annular feeding box at the top of the machine, the undersize passing through the screen into a receptacle underneath, and the oversize sliding down over the screen surface into a launder at the base of the machine.

Revolving with the feeding box are two perforated pipes inside the screen, their function being to prevent blocking the screen apertures by delivering water under pressure against it. Outside the screen, directly opposite the perforated pipes and revolving with them, are two flat baffles, designed to avoid scattering or splashing the pulp.

The standard machine is made 4 ft. wide at the base and contains 24 sq.ft. of available screening surface. With



THE WOOD SCREENING MACHINE

16-mesh screen fitted to it, the machine is said to separate 80 tons of pulp per day of 24 hr., most of which is undersize. The accompanying drawing and photograph will give a clear idea of the construction of the device.

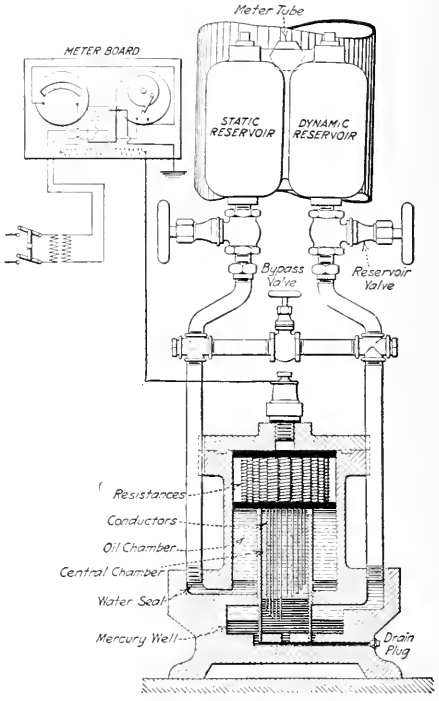
The Republic Flow Meter

The Republic flow meter has been developed recently to such an extent that in measuring steam, water, air or gas, it compares in accuracy and convenience with the standard wattmeter or ammeter. The principle is that of a U-tube containing mercury.

Contact wires of graded lengths are suspended over the mercury in the central chamber, each wire being connected to a resistance immediately above. A circuit is formed of the resistances, contact wires, mercury and ground, a current of given voltage usually 38 volts, being applied. All the resistances are in series with one another, and as the mercury rises as a result of the application of pressure on the surface of the mercury in the large chamber, a number of resistances are short-circuited. A definite quantity of current now flows through the circuit, actuating the indicating, recording or integrating instruments.

The resistances are of such magnitude that the quantity of current flowing at any time is a direct function of the velocity of the fluid flowing in the pipe, and therefore also of the quantity of fluid. The pointer of the indicating instrument moves equal distances for equal increments of velocity of flow.

The form of pitot tube used is a departure. It consists of two tubes extending completely across the pipe, impact holes being provided in one tube at the proper intervals. Each hole is located in the center of an annular ring, the cross-section of the pipe being divided into half as many equal-area annular rings as there are holes. The other tube is the aspiration tube and is identical with the impact tube. These tubes are placed back to back and are inserted in the pipe so that the impact holes will point upstream and the aspiration holes downstream. It has been found by actual experiment that



SECTION THROUGH REPUBLIC FLOW METER

this arrangement of impact holes results in the true mean of the velocities existing in the pipe.

The upstream side of the pitot tube is connected to the dynamic side of the mercury well, and the aspiration tube is connected to the other side of the mercury well. This results in the mercury being elevated in the central chamber to a height proportional to the square of the velocity of fluid in the pipe. The illustration shows that water is not permitted to touch the resistances or the contact wires, because of the oil seal.

A new feature is the micrometer adjustment for raising or lowering the resistance spool from the outside. In establishing the zero point the bypass valve is opened and the height of the contact wires is adjusted until the reading instruments show that no current is flowing.

Any combination of indicating, recording or integrating instruments may be connected to this meter. The Republic Flow Meters Co., of Chicago, is the maker.—*Power.*

Correspondence and Discussion

Concentration Formulas

I have read J. E. Clennell's short article under the heading, "Concentration Formulas," in the *Journal* of Oct. 30. In spite of the growing use of formulas I prefer simple arithmetic where it can be applied, as a formula, concealing its reactions, obscures the whole operation, however correct its results may be. This applies to mine-valuation formulas as well as those for metallurgical operations. The plain arithmetical solution, something on the line of blast-furnace balance sheets, which follows is preferable to the use of Clennell's formula. I respect his data and adopt his assumption that the assay value of the tailings and the concentrates will not be affected by clearing the middlings.

DATA OF CONCENTRATION TESTS

Product	Weight, per Cent.	Assay of Products per Ton, Gold, Oz.	Per Cent. of Total Gold
Concentrates	12.45	6.53	90.8
Middlings	11.45	0.35	4.5
Tailings	70.10	0.055	4.7

The head assay showed gold, 0.895 oz. per ton.

It is desired to find the effects of eliminating the middlings in this statement without actually performing the operation.

Let us assume that we have 100 tons of ore assaying 0.895 oz., which gives us 89.5 oz. of gold in the ore. In the concentrates we have $12.45 \times 6.53 = 81.29$ oz. The middlings will add to this $11.45 \times (0.35 - 0.055) = 3.37$, making a total extraction in concentrates of 84.66 oz. The percentage of extraction is $84.66 \div 89.5 = 94.6$. The former extraction in concentrates was 90.8%, making an increase of 3.8%, which will increase the weight of concentrates proportionately.

DATA ON CONCENTRATION AFTER ELIMINATING MIDDLINGS

	Weight, per Cent.	Per Cent. of Total Gold
Concentrates, 12.45×1.038 =	12.92	94.6
The tailings by difference =	87.08	5.4

Clennell's formulas require one addition, six subtractions, eight multiplications and five divisions. The plain arithmetical method requires only two additions, three subtractions, two multiplications and one division. Efficiency experts would therefore indorse the latter method, which has the added advantage of being clear and easily understood. LOUIS JANIN, JR.

San Francisco, Calif., Nov. 3, 1915.

Physical Control of Employees

The article in the *Journal* of Nov. 6, taken from the "Safety First Magazine" of the Nevada Consolidated Co., is somewhat misleading, in that it gives only one viewpoint. The company's orders of compulsory physical examination caused much dissatisfaction among its employees.

The age limit was placed at 44 years and the examination was so severe that one-half to two-thirds could not pass it satisfactorily. The employees felt that it was only a question of time when the older men and physical incompetents would be gradually weeded out. The company's physicians were unfeeling and arrogant, the men were made to strip, and the examination created much opposition and ill-feeling, the general public, without exception, being in sympathy with the men. The result was that finally the employees gave notice that unless these orders of compulsory physical examination were withdrawn, they would all walk out on Oct. 31, 1915. The company then withdrew the orders, evidently not desiring a strike with copper around 18c.

If this was generally adopted by all the large companies, the men and general public cannot see what would become of one-half or more of the laborers. Would the state take care of them? Is not a skilled workman a better man, past 40, than when 20 to 30 years old? Has he not better judgment, from experience? MINER.

Ely, Nev., Nov. 11, 1915.

Cost of Winter Construction

In the *Journal* of Oct. 2, H. Colin Campbell has taken exception to some of my recommendations under the heading, "Difficulties of Winter Construction."

Mr. Campbell's recommendations should be seriously considered where large masses of concrete are used, but they are hardly applicable to the class of work under consideration. On large concrete jobs of any kind conditions are more favorable than on the small one; they can be made so by virtue of size. The ultimate strength must be more nearly known in order to cut down the mass to a minimum. A smooth clean-cut surface might count for considerable, but in a small mill a little efflorescence is a matter of small moment. Heating the aggregate and mixing water would probably be the cheaper method with a large yardage of concrete, even at the expense of a special heating installation. The increased cost of concrete under these conditions would not reach 50%.

Unfavorable conditions, however, are the rule and not the exception for the average small mill constructed during the cold months in the north. Heavy snows and extreme cold weather, being conceded, make the obtaining of material a difficult task. The average small mill that, as a rule, the operating engineer will be called upon to construct does not require a large yardage of concrete, and very often it is not an easy matter to arrange for heating. Midwinter construction is safe and feasible as long as the company will stand for the extra expense, which will often reach 50% in concrete work.

Trautwine and other authorities claim that freezing will not damage concrete after it obtains the preliminary set. I have never attempted to protect concrete after 12 hr. when the heating method is used and have never seen the least sign of failing, even in a mortar block, which is about as severe a test as can be found in a mill. Twelve hours is ample time to allow for the initial set with any good grade of portland cement. However, freezing may give an apparent hardness, and care should

be used not to remove the forms too quickly, or impose undue loads, which could easily produce failure when the concrete thaws out. The ultimate strength could hardly be materially reduced if proper care be taken. Freezing will retard the final set, but it is difficult to find a good reason for material damage after the hydration has taken place.

There appears to be a variance of opinion about the use of integral salts, but the consensus of opinion seems to be that the salts in themselves can cause no damage if not used to excess. This being so, why should their use damage the concrete if they keep it from freezing? The slow crystallization due to a low temperature might possibly lower the ultimate strength, but the reverse is true if poured in warm weather. Trautwine gives the following experiment, which goes to prove that concrete made of portland cement in cold weather and kept from freezing by the use of salt will not have a lesser ultimate strength, although concrete made of natural cement under the same conditions will have.

EFFECT OF COLD AND MIXING SALT WATER

Specimens; compressive strength of 12-in. cubes of portland- and natural-cement concrete: 8 cubes Atlas Portland, 1 cement: 3 gravel (2 sand, 1 pebbles): 4 crusher-run hard limestone; 8 cubes Louisville natural, 1 cement: 2 gravel: 3 stone. Same as used in track-elevation masonry by C., M. & St. P. Ry. Treatment: All cubes made by same person in molds of 1-in. lumber, and left in molds until broken. Results:

	Portland		Natural	
	Temp., °F.	Lb. per Sq.In.	Temp., °F.	Lb. per Sq.In.
Cube in warm office, 28 days	80 to 18	1,290†	85 to 40	300
Cube in warm office, 28 days	80 to 18	1,290†	85 to 40	Defective
Cube outdoors*, 28 days	57 to —24	902‡	57 to —10	200
Cube outdoors*, 28 days	57 to —24	690‡	57 to —10	256
Cube in office, 28 days	85 to 32	1,290†	85 to 40	352
Cube outdoors*§, 28 days	57 to —24	1,290†	57 to —10	237
Cube outdoors*§, 28 days	57 to —24	1,290†	57 to —10	247

* During first part of 28 days temperature fell to —10 and —20° F., afterward thawing during day and freezing at night.
† Flaked slightly
‡ Cold believed to have retarded setting.
§ Mixed with salt water, 1 pt. salt to 10 qt. water.

Small quantities of concrete are often needed during the cold months around a mining property where heating is out of the question. I have had several occasions to use salts for such purpose; from all appearance the concrete was as firm as that put in during warm weather. It may have a lesser ultimate strength, but it is practical. The engineer with difficult winter work on hand is after practical results, namely, a sufficient factor of safety; he bothers his head very little about the surface appearance of a wall or foundation soon to be spotted over with slime, or about a few hundred pounds, difference in ultimate strength.

HARRY T. CURRAN.

Denver, Colo., Oct. 30, 1915.

Newfoundland's Mineral Resources

In the article on "Newfoundland's Mineral Resources" in the *Journal* of Oct. 23, Mr. McDonald failed to mention roofing slate. During the years 1901-04 the Newfoundland Slate Co. operated a quarry on Trinity Bay and produced a considerable quantity of high-grade purple and green roofing slate, which was sent to England and brought as high a price as the best Welsh slate. I understand that the reason for closing down the quarry was the death of the manager and moving spirit of the company and not the exhaustion of the deposit.

Timbering in New York Subway

In the *Journal* of Oct. 23 was published a letter of mine discussing Mr. Barbour's article on "Timbering in the New York Subway," which appeared in the *Journal* of Oct. 2. Following my letter was appended a criticism of it by Mr. Barbour, which shows a misconception of my statements. The object of my letter was to show that the principle of square-setting is not applicable to subway needs, because it depends on being wedged into place; while traffic vibration on the street structure and lack of abutments, including a light street structure, do not meet this requirement.

He says: "The statement that square-set timbering is not a self-contained structure applies only if one considers it in the nature of a house, which it is not. Square-set timbering underground is certainly self-contained when it is properly wedged in place, and it is not intended to be used any other way." I do not agree with this definition of square-setting. Underground it is not self-contained, but is wall-contained. In subway use it would be a house of cards, because of the impossibility of properly wedging it.

The next comment in the criticism is: "He also states that it is obvious that the use of continuous transverse members from side to side would be more secure than transverse members built up of short-length members tied together," and Mr. Barbour goes on to say: "Theoretically true, but 60-ft. cross-members, as would be required in the subway, are a scarce article, etc. . . . The only long cross-member used was one composed of two 24-in. I-beams at the ends, connected by two channels in the middle, and this construction as well as the entire framing of the bents, etc., . . . not only invited jack-knifing but got it."

The criticism has here confused the meaning of my statement by not fully quoting the paragraph. The full quotation states that square-setting could not be properly wedged in a subway cut, with the consequent necessity of tying and bracing and the disadvantage of short transverse members instead of long ones to better tie the structure together. I do not understand how this can be construed to mean that because the Broadway timbering had one long member in each bent I recommended the timbering. The structure jack-knifed because of no diagonal bracing between the bents, not because of the long member. It would have been the same or worse in this respect with cross-members built up of short lengths.

As to the comment about continuous cross-members being a scarce article, I did not refer to a single rolled I-beam or a single stick of timber, but to built-up continuous beams.

The last paragraph of my letter reads: "The best practice in subway timbering therefore includes continuous cross or transverse members to distribute loads, to brace the sides of the excavation and to tie the structure together more securely; the requisite rangers and lagging to hold the sides of the excavation; sufficient posting in all tiers and secure vertical diagonal bracing, both transversely and longitudinally, of all tiers of posts; sufficient struts or spacers and adequate street structure."

In the criticism only the first part of the foregoing paragraph is quoted, and the criticism states: "Inasmuch as the timbering in question did not brace the sides of the excavation which caved in and caused the fatal disaster,

I submit that the practice was not proper, even though it is considered the best practice in subway timbering."

On my part I submit that I made no statement whatever to the effect that the timbering of the accidents constituted the best practice; for if my whole definition on this point had been quoted, it can be readily seen that the timbering at the scenes of the accidents could not be construed as coming within the definition. It was lack of shoring that caused the rock slide, and lack of diagonal bracing caused the collapse of the street structures. JOHN SEWARD.

West Nutley, N. J., Oct. 30, 1915.

Roosevelt Tunnel Portal

My attention has been called to the fact that the pictures of the Roosevelt tunnel portal, published in the *Journal* of Oct. 2 and 23, do not seem consistent.

The one on page 683 of the issue of Oct. 23 was taken a few months after work was started. At that time I walked to the breast of the tunnel, about 200 ft. in, without getting my shoes muddy. The tunnel was dry until the main water course was cut, about 14,000 ft. from the portal. At the time the second picture was taken, recently, the water was about 2 ft. deep on the floor of the tunnel at the portal, but no work had been done there for years. As soon as the connection between the intermediate shaft and the tunnel was made, work was carried on through the shaft, and as soon as the El Paso shaft was sunk to the tunnel level the work was carried on through that shaft, which is the present practice.

Denver, Colo., Nov. 11, 1915. T. H. SHELDON.

Valuation of Ore Deposits

Misther Editor—'Tis interestin', the way some fellies figgers out the values av ore dayposits.

The other day Tim an' me was studyin' out the dope on wan av thim idle-rich mines in Arizony. Did ye iver notice how some av the idlest mines is bragged about as bein' the richest, jist like people?

Well, annyhow, there was a big bunch av maps, rayports, misfires an' John Hodgeses, certiffycuts, et cetery—enough paper to feed a dozen goats an' to indigest the wan they was intinded for—dished up by an imminent consultin' injineer with the assistance av siveral minin' injineers, assayers an' other boosters. Whin we got the stuff all b'iled down an' poured on the colander av pessimism, jist like Kathleen does with a bale av greens for dinner, we diskivered the follyin': (1) The old stopes was all caved in. (2) The shaft an' the drifts was timbered so tight that no wan cud luk at any walls or roof without pullin' things down like old Samson. (3) Ivery wan av thim injineers said he'd accept the figgers av the former superintendent (which was dead 12 year) on the assays av the samples taken whin the mine was bein' diviloped. (4) The only ividence av values was wan big chart av 479 assays taken on wan level, tellin' the number av inches av ore an' all that kind av thing.

It tuk Tim four days, not countin' three hours overtime, av multiplyin' inches, dollars, feet, assayers, et cetery; workin' like a full-grown rabit on all thim things he called faethors av numeraytor an' faethors av denominaytor. Whin he got through, the best raysult he cud get for the average value av all the ore was $11.17; while the big answer, han'somely engrossed at the bottom av the chart called for $27.63. So I sez to him, sez I, "Tim, now ye see what comes av playin' at bein' a delishency injineer whin the minin' business was dull. Have ye thried addin' up all the assay raysults an' dividin' by 479?"

"Why, Bill," sez Tim, "wud ye ignore complately all thim faethors av width av ore an' irregular intervals av samplin'? Ye're no injineer at all, at all."

"Sure, not," sez I, lightin' up me pipe again, "bein' only a prospector, like. But ye must raymimber that I sold a mine wance, mesilf."

Well, we tiggered out the av'rage in the schoolboy way an' got the same as on the big chart; which was the wrong answer for a buyer.

Now, misther editor, do ye suppose the imminent consultin' injineer was to get fifty-fifty if the mine was sold?

Brooklyn, Oct. 26, 1915. BILL MCGINTY.

NEW PATENTS

United States patent specifications listed below may be obtained from "The Engineering and Mining Journal" at 25c. each. British patents are supplied at 40c. each.

AGITATOR. Harry R. Conklin, Joplin, Mo. (U. S. No. 1,160,848; Nov. 16, 1915.)

ALLOYS—Apparatus for the Electrolytic Manufacture of Alloys of Light Metals with Heavier Metals and the Continuous Treatment of Such Alloys for Obtaining Final Products. Edgar Arthur Ashcroft, London, England. (U. S. No. 1,159,154; Nov. 2, 1915.)

AMALGAMATOR—Apparatus for Extracting Precious Metals. Victor I. Zachert, San Francisco, and Pierre A. Brangier, Agnew, Calif., assignors of one-third to Victor G. Bonaly, San Francisco, Cal. (U. S. No. 1,160,485; Nov. 16, 1915.)

CAR COUPLING—Automatic-Clench Car Coupling. William T. Lilly and Andrew J. Lilly, Glen Morgan, W. Va., assignors of one-half to Grover C. Hedrick, Beckley, W. Va. (U. S. No. 1,158,515; Nov. 2, 1915.)

CHARGING and Push-out Apparatus for Furnaces. William M. Neckerman, Youngstown, Ohio, assignor to The Youngstown Sheet and Tube Co., Youngstown, Ohio. (U. S. No. 1,159,702; Nov. 9, 1915.)

CORROSION—Method of Preventing the Rusting of Iron and Steel. Daniel F. Comstock, Brookline, Mass., assignor to Comstock & Wescott, Inc., Boston, Mass. (U. S. No. 1,159,748; Nov. 9, 1915.)

DRILLS—Drill-Steel-Turning Device for Percussive Fluid-Operated Drills. Caid H. Peck, Waverly, N. Y., assignor to Ingersoll-Rand Co., Jersey City, N. J. (U. S. No. 1,160,648; Nov. 16, 1915.)

CYANIDING—Extraction of Metals from Their Ores. Hugh M. Leslie, Glasgow, Scotland. (U. S. No. 1,158,514; Nov. 2, 1915.)

ELECTRIC FURNACE, Intended Chiefly for the Manufacture of Nitrides. Georges Coutagne, Lyon, France. (U. S. No. 1,158,899; Nov. 2, 1915.)

FLOTATION—Improvements in or Relating to the Separation of Metallic Sulphide Ores. Minerals Separation and De Bavays Processes, Ltd., Melbourne, Australia. (Brit. Nos. 19,273 of 1914 and 19,374 of 1914.)

GOLD-SAVING MACHINES. John T. Voigt, Richmond Beach, Wash. (U. S. No. 1,160,550; Nov. 16, 1915.)

JIG—Ore-jig. Frank Franz and Eugene R. Day, Wallace, Idaho. (U. S. No. 1,160,502; Nov. 16, 1915.)

LEACHING—Apparatus for Leaching Ores and the Like. Percy A. Robbins, Timmins, Ont. (U. S. No. 1,160,200; Nov. 16, 1915.)

LEAD ALLOYS—Hard Lead Alloys. Francis C. Frary, Minneapolis, and Sterling N. Temple, St. Paul, Minn.; said Temple assignor of one-sixth of the whole right to said Frary. (U. S. Nos. 1,158,671, 1,158,673, 1,158,674, and 1,158,675; Nov. 2, 1915.)

METAL COVERINGS—Method of Removing Metallic Coverings from Other Metals. Hans Foersterling and Herbert Phillipp, Perth Amboy, N. J., assignors to The Roessler & Hasslacher Chemical Co., New York, N. Y. (U. S. No. 1,160,590; Nov. 16, 1915.)

PEAT—Apparatus and Process for the Heat Treatment of Peat. Nils Testrup, London, England, and Thomas Rigby, Dumfries, Scotland, assignors to Wet-carbonizing Ltd., London, England. (U. S. Nos. 1,160,463 and 1,160,464; Nov. 16, 1915.)

PRECIPITATING APPARATUS AND METHOD. Harry R. Conklin, Joplin, Mo. (U. S. Nos. 1,160,845 and 1,160,850; Nov. 16, 1915.)

SCREEN—Vibrating Screen. Randall P. Atkins, Denver, Colo., assignor to Colorado Iron Works Co., Denver, Colo. (U. S. No. 1,160,812; Nov. 16, 1915.)

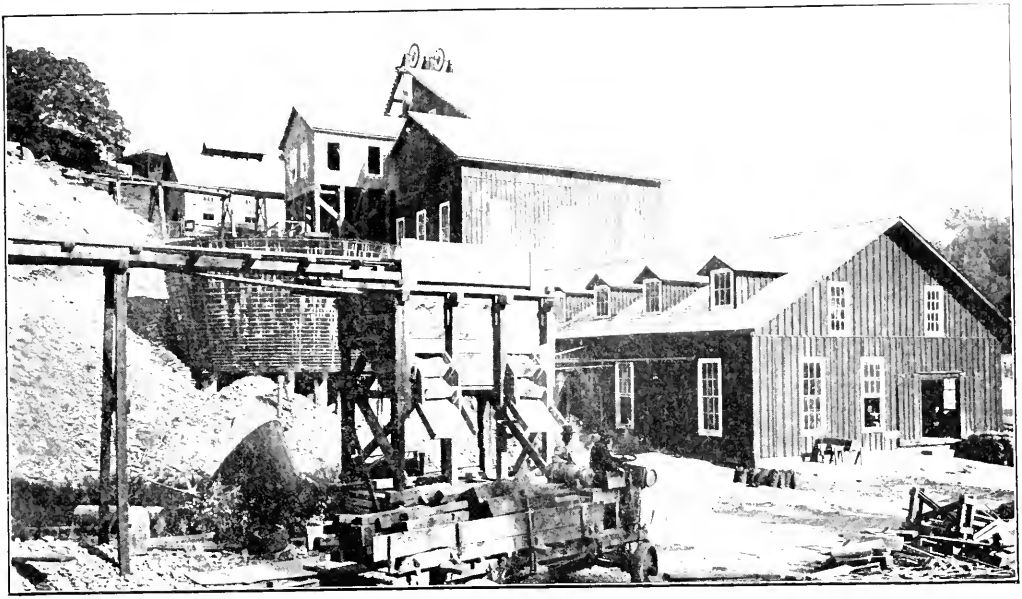
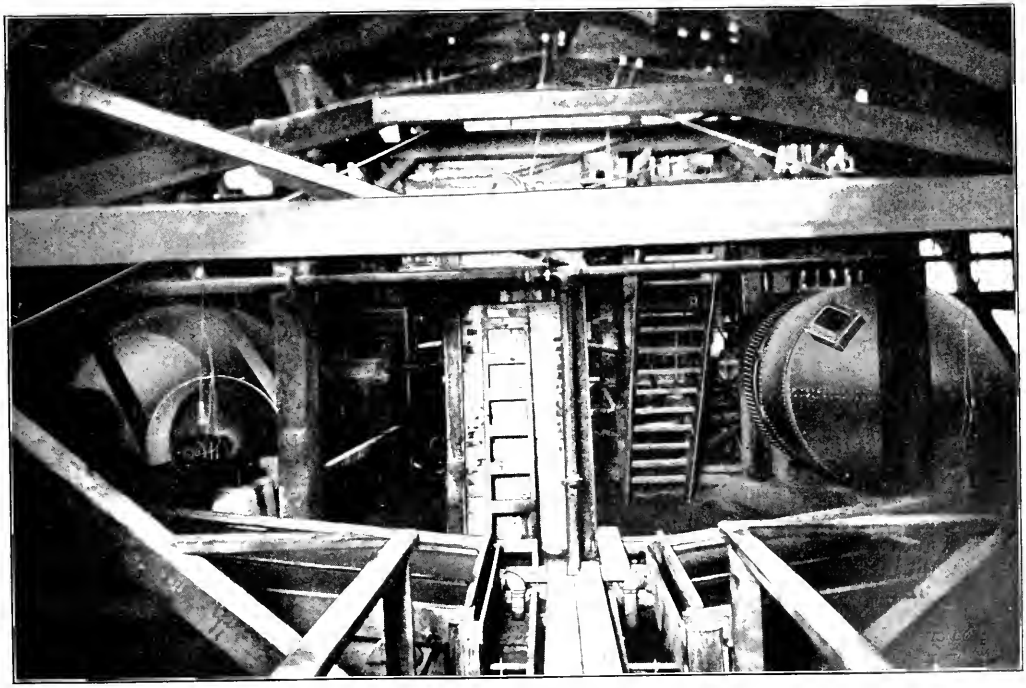
1—The stamp mills at Terraville. 2—The Father de Smet 100-stamp mill. 3—The pumping station at Hanna, where three 2,000-gal. steam pumping engines are being replaced by Jeanesville electric-driven centrifugal pumps. Water is elevated 387 ft, and then flows by gravity to Lead. 4—Electric generating station at Englewood. Water pumped over the divide is here utilized to generate power, using a Pelton wheel. 5 and 6—Interiors of Englewood power plant. 7 and 8—In the regrinding plant at Lead, showing tube and Hardinge mills



The mill uses amalgamation, concentration and cyanidation, handling the usual type of Mother Lode ores. It is equipped with 40 stamps and Hardinge mills for regrinding. The concentrates are cyanided in a Trent agitator and replacer, and solutions precipitated with zinc dust. The mill has a capacity of 300 tons daily



AN INTERIOR VIEW OF THE AMADOR CONSOLIDATED MILL

The stamps, regrinding mills and amalgamation tables are shown. The operation of this mill was described in the "Journal" of Aug. 14, 1915

Braden Copper Co.'s Concentrator at Sewell, Chile*

SYNOPSIS—A condensed description of the Braden Copper Co.'s ore-dressing equipment. The main features of the operation are briefly explained by the Braden mill staff.

The crushing plant and concentrator of the Braden Copper Co. at Sewell, Chile, are about two kilometers west of the mines on the northern side of the Teniente River. The topography of the mill site is such that full advantage is taken of a gravity flow of the ore, whether it is in its dry state as it comes from the mine, or after the addition of water as it is handled in the mill. The difference in elevation between the top of the coarse-ore bins, where the ore is received from the mine, and the bottom of the filter-press plant is 403 ft. The area covered by the entire concentrating plant itself is 130,000 sq.ft.

The Coarse-Crushing Plant

The ore is transported from the mine to the coarse-ore bins by means of an electric railroad. The bins have a storage capacity of 2,300 tons. Mechanical feeders deliver the ore to a belt-conveyor system that carries it to the crushing plant. The crushing plant is divided into two sections having the same number of machines and the same rated capacities; only one section will be described. The ore passes over a 1½-in. grizzly, the oversize falling directly into a gyratory crusher; the fines join the crusher discharge, which has been reduced to an average diameter of less than 2 in. These two products are then crushed to ⅞ in. in a pair of rolls 6 ft. in diameter and 20 in. wide.

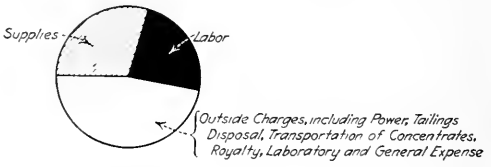
The discharge of the 72x20-in. rolls is divided into two parts, each passing into a trommel having diagonal openings, 6x30 mm. The undersize is carried direct to the fine-ore bins by means of conveyor belts. The oversize is fed into a 48-in. Symons disk crusher that crushes the ore to ⅝ in. between two manganese-steel disks rotating in the same direction and at the same speed, but supported at an angle to each other. The discharge of the Symons crushers passes over Colorado Iron Works Impact screens with openings 6x30 mm. The undersize goes to the fine-ore bins by means of the conveyors already mentioned. The oversize is crushed in two sets of 36x15-in. rolls. The discharge of these rolls is raised by a bucket elevator to another set of Impact screens, the oversize being divided, approximately one-third to the two 36x15-in. rolls mentioned above, and the remainder to two more 36x15-in. crushing rolls, for further grinding until all the ore will pass the 6x30-mm. openings of the screens. The fine-ore bins have a storage capacity of 3,000 tons.

Concentrating Mill in Three Sections

The crushed ore is delivered to the concentrator building by means of belt conveyors. The mill is divided into three sections, each with a nominal capacity of 1,200 tons per 24 hr., only one of which will be described as the other two are similar.

From the final belt conveyor the ore passes over four Impact screens with 25 openings to the square inch, making a separation between the smaller particles, which can now receive their first concentration, and the larger ones, which require further grinding in order to liberate the sulphides. The oversize from the screens is fed to two sets of rolls, then to an elevator, the discharge of which joins the fines that have passed the screens. At this point water is added and the ore flows to four trommels with screens having the same-sized opening as the Impacts. The material passing through these trommels is fed to six Wilfley tables. The concentrates flow to the collecting tanks at the foot of the mill, while the table sands, which need further grinding, are conducted to eight Hardinge mills; the oversize from the trommels is also fed to these mills.

The Hardinge conical mills make 28 r.p.m. and are half-filled with pebbles having a maximum diameter of 5 in. All the discharge is now run to two drag classifiers, the sands from which are concentrated on six Wilfley tables, the concentrates going to the collecting tanks, and the reject sands to the next floor of Hardinge mills for further grinding. On this floor there are six mills, which reduce the reject or table tailings to the size required for the final concentration. Each of these mills is operated in closed circuit with a drag classifier, the overflow of which runs direct to the flotation plants.



DISTRIBUTION OF CONSTRUCTION EXPENSE

Ore Ground to 60-Mesh for Flotation

The ore has now been ground so that all but 10% will go through a 60-mesh screen. The final concentration is effected by means of the Minerals Separation process. This is carried out in eight standard M. S. units that treat the tonnage handled by the three mill sections. The float from the last two boxes of each unit is low in copper and is collected separately and retreated, being pumped back to join the original feed.

The tailings, from which most of the copper has now been extracted, are all collected into one launder, passed through a sampler, and then conducted down the valley to the tailings dam, where they are stored.

The concentrates are collected in concrete tanks at the foot of the mill and loaded by means of a crane into railroad cars for removal to the smelting works. The overflow of these tanks, consisting of sulphide slimes too wet to be smelted, is run to Dorr thickeners. The thickened concentrates are further dewatered in two types of machines: the Kelly press and the Oliver filter. The

*Excerpts from a preliminary article by the Braden mill staff in "Teniente Topics" for October, 1915.

product of both machines is loaded directly into railroad cars for transport to the smelting plant.

OPERATING DATA, BRADEN MILL

Tons per man per day	8.50
Kilowatt-hours per ton milled	29.60
Acid per ton milled, lb.	7.00
Tar oil per ton milled, lb.	2.00
Fuel oil per ton milled, lb.	0.30
Local pebbles per ton milled, lb.	8.75

On account of the situation of the plant in a foreign country, the long distance from the main base of supplies, the duties and ocean freight on all sorts of material bring the item of supplies up to 60.4% of the total direct milling costs. The percentage of total costs assessable to the various departments, for labor and supplies respectively, is shown in an accompanying table. The relative proportion of the total milling charges is indicated in the diagram.

DISTRIBUTION OF DIRECT MILLING COSTS AT BRADEN

	Labor %	Supplies %
Coarse-ore bins and conveyors	4.07	2.51
Crushing plant	21.29	16.02
Fine-ore bins, conveyors, mill rolls and screens	9.02	7.17
Table concentration	7.04	2.97
Hardinge mills	21.98	25.00
Oil flotation, main plant and retreatment	22.81	42.58
Concentrate handling	8.33	1.14
Filtering M. S. concentrates	5.46	2.61
	100.00	100.00

⁂

Interstate-Callahan Report

The third annual report of the Interstate-Callahan Mining Co., Wallace, Idaho, for the fiscal year ended June 30, 1915, has been issued. For the fiscal year ending June 30, 1914, there was an operating loss of $99,315. During the year just closed, this deficit was wiped out, dividends aggregating $697,597 were paid and a surplus of $1,094,862 was accumulated. Ore was extracted during the year from four levels, only development work being done below No. 4. There is enough ore above No. 6 to last the mill for four years. An average of 180 men was employed in the mine and mill, and 309.5 tons of ore per day was sent to the mill.

Shipments of concentrates and crude ore totaled 41,963 tons. Income totaled $2,161,177.53, distributed as follows: Crude lead ore, 246 tons, $6,451; crude zinc, 8,473 tons, $421,238; lead concentrate, 2,563 tons, $90,096; zinc concentrate, 30,681 tons, $1,628,499; miscellaneous income, $14,895. Expenditures totaled $569,404.38, divided as follows: Mining and milling, $470,967; interest, $18,088; improvements, $80,350. The surplus after paying $697,597.50 in dividends was $894,175.65, to which is added $300,000 derived from the sale of bonds, less $99,313.64 loss in 1914, leaving $1,094,862.01 in the treasury.

The report of C. W. Newton, mine superintendent, covers only the first six months of 1915. Development work during this period totaled 1,510 ft.: Shaft, 25 ft.; crosscuts, 639 ft.; drifts, 814 ft.; raises, 32 ft. Ore mined totaled 56,025 tons: No. 2 stope, 3,921 tons; No. 3 stope, 19,924 tons; No. 3½ stope, 11,433 tons; No. 4 stope, 18,478 tons; development 2,269 tons.

⁂

Feldspar Production Marketed in the United States in 1914 was 135,419 tons, the largest annual recorded output. The sales of crude spar were 85,905 tons, and of ground spar 49,514 tons. The quarries are, with a single exception, restricted to the Eastern seaboard states, the exception being in California. It is chiefly used in the manufacture of pottery, enamel ware and electrical ware, according to the Geological Survey.

Mineral County, Montana, Mining Notes

By Hubert I. Ellis*

There is greater activity now in mining and prospecting in Mineral County, Mont., than for many years past. The principal centers of activity are Saltese, in what is sometimes known as the "East Cœur d'Alenes," and Superior, the county seat. The Superior mineral belt is probably better known as the Iron Mountain district, from the old Iron Mountain mine and the station of the same name on the Northern Pacific Ry. about a mile from Superior, which is on the C., M. & St. P. Ry.

The earliest mining in the area tributary to Superior was on Cedar Creek, which empties into Missoula River from the south about a mile above the town. Placer gold was discovered on Cedar Creek in 1869 and soon afterward on certain of its head-water tributaries, notably Oregon, California and Snowshoe Gulches, and on Freezeout and Deep Creeks. Walla Walla, Wash., was the supply center, provisions and such equipment as was essential being freighted to the mines by pack-train. Flour sold for $18 a hundred, according to an old account book found in a deserted cabin, and wages were $5 a day.

Early Mining Activities in the District

Some of the placers were rich, and it was not unusual for a small crew to average $80 or more each per day. Cedar Creek alone is credited with a production of nearly $3,000,000, which came chiefly from the upper portion of the creek and from Oregon and California Gulches. Drifting in the early days and hydraulicking at a slightly later date were the usual methods of working, although some deposits were worked by opencuts. The mining of placer gold is no longer an important industry, although the Cedar Creek Gold Mining Co. is operating a dredge 14 mi. from the mouth of the creek and 4 mi. above the Amador copper mine. The dredge was installed in 1907 and has worked every summer since. It was originally planned to operate throughout the year, and a steam-power plant for generating electricity was built 2 mi. below the dredge. It was soon found that the freezing of the surface precluded the possibility of winter dredging, and water power, being plentiful in summer, was substituted for steam for driving the generators. Water is taken from Cedar Creek, ¾ mi. below the dredge, and led through wood pipe of about 24 in. diameter to the power plant. The dredge, which seems to have been a money-making enterprise during the last three or four years, has a large area of practically virgin ground ahead, some of which has been prospected by Keystone drill.

The only producing lode mine on Cedar Creek is the Amador, 10 mi. from the mouth of the creek. A deposit of high-grade copper ore was found by the placer miners in cleaning bedrock, but no attention was paid to it at the time. Lode claims were eventually located, and a large amount of work was done by the old Amador company, which obtained the claims from the original locators. An adit on the vein was started on the left limit of the creek, but the showing in this seems to have been less encouraging than that in the creek bed and a winze was sunk a short distance from the portal. Ore was stoped to a

*Mining engineer, Kellogg, Idaho.

depth of 400 ft. A standard-gage railway was built to the mine from the Northern Pacific tracks at the mouth of the creek, and a smeltery was built at the junction where the town of Amador, now deserted, was founded. Partly owing to dissension among the stockholders, the mine was closed down in 1907, after a career said to have been featured by extravagance and general mismanagement. During the current year it has been taken over by the Intermountain Copper Mining Co. and reopened to a depth of 400 ft., on which level there is a 300-ft. shoot of milling ore ready for stoping. The flume, which diverts water from Cedar Creek and delivers it to the compressor plant at the tunnel portal, has been repaired. A new 100-ton concentrator is being built to treat the ore by jigging, table concentration and flotation, and it is expected to start early in November.

Prospects Attracting Attention

There are, near the Amador, other promising prospects that are receiving considerable attention. On Mary Ann gulch, 5 mi. below the Amador, is the Golden Sunset gold prospect, owned by Kittinger, Shattuck and associates. The ore is rich, but its occurrence is irregular. On the Gold Crag, at the head of Cedar Creek, Fuller brothers have driven 450 ft. of a 750-ft. crosscut tunnel to tap the vein at 500 ft. under a promising surface showing. On the divide between Freezeout and Snowshoe Creeks the Gildersleeve brothers have traced a copper-lead vein several hundred feet. At the head of Oregon Gulch and Deep Creek there are several gold prospects on which considerable work has been done, but nothing of value has been found.

One of the most promising properties in this area is that of the Clearwater Gold and Copper Co., which lies across the range on the Little North Fork of Clearwater River, in the State of Idaho. Two adits have been driven on the vein, the upper 1,200 and the lower 1,400 ft., and a winze has been sunk 100 ft. from the lower adit on an oreshoot 20 ft. in width. A small sawmill has been built, and the property is equipped with compressor and air drills. Only the lack of transportation facilities prevents this mine entering the list of producers. The most feasible outlet, in the absence of a railway, is probably by aërial tram to the Amador mine, a distance of 15 mi. over comparatively easy country.

The Iron Mountain, on Flat Creek, is the most important of the mines lying northwest of Superior. It is an old producer, the first mining having been done about 1887, and thousands of tons of silver-lead ore has been treated in the mill. The mine was closed in 1898, when the Montana law requiring two openings went into effect, and was practically idle until 1906, when work was started on a 5,680-ft. adit cutting the vein at a depth of 1,600 ft. A winze was later sunk, and the deepest workings are 2,200 ft. from the surface. Shipments of crude ore and concentrate were made regularly during the last two years until this summer, when the Federal Mining and Smelting Co. bid in the property at sheriff's sale for $110,000. The mill is receiving a thorough overhauling and will be operated.

Near the mouth of Flat Creek the Gildersleeve brothers have installed two Brookwater jigs to rework the old Iron Mountain tailings for zinc and lead, and have recovered as high as 3,000 lb. of 30% zinc concentrates in 24 hr. The operators plan to build a larger mill and will experiment with regrinding and flotation.

There are several copper prospects in the vicinity of Superior on veins associated with persistent dikes of a dark-colored basic rock, probably diabase. Oxidized copper minerals and some sulphides appear on the surface at intervals for several miles, and several bodies of commercial ore are reported, but insufficient work has been done to determine their true value. At the Superior-Montana group, on Kelly Gulch, a 470-ft. adit has been driven on one of these deposits; the copper ore carries $6 to $60 per ton in gold, but its occurrence is irregular. McKinnon has recently found a shoot of shipping ore on the same vein on Spring Gulch, and Whitmarsh, on a similar vein at the head of Thompson Creek, reports several feet of ore, much of which can be shipped crude in the face of a crosscut tunnel.

The Little Anaconda, at the head of Deep Creek and on the continuation of the Iron Mountain lode, is idle at present, the last shipments having been made two years ago. The adjoining Glen Metals mine is under lease to C. B. Etnier. The property has 3,000 ft. of development work on two veins, one of which is opened to a depth of 1,400 ft. and the other to 800 ft. A shipment of 65 tons taken from a shoot 1 to 4 ft. wide and 400 ft. long averaged 15% Zn, 20% Pb, and 10 oz. Ag per ton. At the eastern end the shoot carries 25% Pb and 10 oz. Ag. Shipments will be made from this portion to Northport as soon as the new plant is completed. Driving on No. 2 vein has been under way since Sept. 1; the face shows 7 ft. of milling ore. The King & Queen has been shipping for several years, and preparations are making for reopening the Little Pittsburg. The Red Elephant gold mine is working on a small scale, and the O. R. & N. is driving tunnel by contract.

Near Saltese, on Packer Creek, the Last Chance, which has shipped considerable high-grade silver ore, is being reopened. The Tarbox, Bryan and Hemlock, also on Packer Creek, are being developed. On the Hemlock drifts from the 150-ft. shaft show a shoot of lead-silver ore several hundred feet long. The Wilson Mining and Smelting Co. owns two groups of claims, one lead and the other copper. A crosscut is driving to cut the copper vein at a depth of 125 ft., and it is planned to resume work on the lead group during the winter. From the head of Silver Creek the Richmond is shipping copper-gold ore at the rate of four cars per month. A contract has been let for an aërial tram a mile long to deliver ore to the railway at Adair.

Natural Advantages Warrant Greater Development

Considering the varied mineral resources of Mineral County, it is surprising how little prospecting, except of the most desultory sort, has been done in recent years. The district is served by two railways, the branch of the Northern Pacific to the Cœur d'Alenes and the main line of the Chicago, Milwaukee & St. Paul, and since most of Mineral County drains into the Missoula River, transportation is a simple problem. Power at reasonable rates is available from Thompson Falls, and there is sufficient water in the creeks for many of the mines to have their own plants. Timber of satisfactory grade is abundant. Years of work on the Amador and Iron Mountain mines have demonstrated the continuity of the orebodies, and it is highly probable that new mines will be opened as a result of the present increased activity.

Editorials

Revision of the Mining Laws

Great interest is being exhibited in the convention to be held in Washington on Dec. 16, 1915, which was called by the Mining and Metallurgical Society of America and is to be conducted under its auspices. The purpose of this gathering of mining men is to urge upon Congress the desire of the citizens engaged in the mining industry that the mining laws of the United States be revised as speedily as possible. Upon this there appears to be remarkable unanimity of opinion. It is agreed, moreover, that there should be no piecemeal revision, but a thorough coördination of the whole system: and that a new law providing for this should be drafted upon the basis of the findings and recommendations of a commission to be appointed by Congress to study the subject. Upon these principles the Mining and Metallurgical Society of America, the American Mining Congress and the American Institute of Mining Engineers have taken formal action in perfect agreement, while many of the local mining societies of the country have done the same thing.

The need for a revision of the mining laws has been agitated for a good many years. Society after society has voted in favor of it, commission after commission has recommended it, but the final step to bring it about has not yet been taken. There are certain reasons for this, such as the inertia of Congress, the opposition of certain persons who conceive that their private interests will be adversely affected and the hugeness of the task of writing a new law. In discussions of this question some congressmen have offered to introduce and push any bill that the mining societies would put in their hands, but this was beyond the means of the societies. The preparation of such a bill—assuming the work to be thoughtfully done—is a task involving a great deal of time and expense. This is why the study of the question, the hearing of opinions and wishes in all parts of the country and the drafting of a bill should be delegated to a commission of congressional authorization. Such points as these ought to be brought out in the forthcoming convention.

The Mining and Metallurgical Society of America has had mining-law revision under consideration for a good many years. The report of its committee on mining laws is probably the most instructive literature upon the subject that has been offered. Following this report and the discussion of it in meetings of the society, a series of resolutions was submitted to the membership. Some of these resolutions were carried by an all but unanimous vote, others by only a bare majority, illustrating the nature of the differences in opinion that develop when details come into question. In issuing its invitations to the convention in Washington, the council of the Mining and Metallurgical Society said that it would offer only those resolutions upon which its membership was substantially unanimous. At a meeting of this council last week that action was rescinded, and it was decided to offer only those resolutions embodying the broad principles that there should be a complete and coördinating revision of the mining laws and that a commission to study the matter should be authorized by Congress. All other points, such as the question of extralateral rights and the question of discovery as a prerequisite to location, will come naturally within the purview of such a commission and need not be discussed at this time, when the main thing is to get a commission.

A matter which will, however, be usefully discussed in Washington pertains to the nature of such a commission—whether it should consist of three members, or five, or seven; whether lawyers or mining men should predominate in it; whether it should be paid or unpaid. These and many other questions are of vital importance. The great idea in the forthcoming meeting, however, is for mining men from all parts of the country to assemble in Washington and let Congress know that they want to have something done; and that, moreover, they will be able to propose a specific, practicable and conservative program, respecting which everybody will be substantially in agreement.

The Kennecott-Braden Deal

One of the most curious transactions in copper-corporation affairs is that which was announced last week, whereby the Kennecott Copper Co., operating mines in the Copper River region of Alaska, is to take over the Braden company, operating mines in Chile; and furthermore, is to acquire the interest (about 400,000 shares) of the Guggenheim Exploration Co. in the Utah Copper Co. No reason based on economy in operation of these far-apart mines has been advanced, nor has the public been apprised of any explanation of what it is hoped to accomplish.

The Kennecott, Braden, and Guggenheim Exploration are concerns in which the Guggenheims are largely interested. The Guggenheim Exploration Co., which is essentially a holding company, has been advertised in the squibs in the Wall Street journals as about to be dissolved. The Braden company has been borrowing several millions of the cash assets of the Guggenheim Exploration. The Kennecott company, which represents a huge investment in Alaska by the houses of Morgan and Guggenheim, was offered to the public for investment several months ago, in connection wherewith there has been a shrewd stock-market propaganda. The Utah Copper Co. plays no part in the deal, but the Guggenheim Exploration Co. owns a large block of its shares.

The Braden company owns a great mine, but it has experienced disappointments and probably was still far short of the time when it, going alone, could safely begin the payment of dividends. On the other hand, the Kennecott company, which made its début in Wall Street about the time when copper rose to 20c. per lb. last spring and soon afterward discovered what was heralded as the richest copper bonanza ever known, will soon be

in a position to begin the payment of dividends. The Braden and Kennecott mines are, in short, the antitheses of each other. Both are situated in remote regions and are subject to violent vicissitudes of climate, labor conditions, etc. The Kennecott mines are far up in the Northern Hemisphere and the Braden mines far down in the Southern. The latter have low-grade ore, a lot of it, and the probability of long life. The Kennecott mines have phenomenally high-grade ore, but there is doubt as to how long it will hold out. The idea of the Braden-Kennecott combination appears to be to average things. The Braden stockholders will probably not object to this. The Kennecott company is too new a thing to have a large list of stockholders of the investment class.

The strangest thing in the deal is the taking-over of the Utah shares from the Guggenheim Exploration Co., the latter receiving Kennecott shares in exchange. If the Guggenheim Exploration Co. is going into liquidation and is going to distribute its assets among its stockholders, the latter will get Kennecott shares instead of Utah shares. The principal Guggenheim stockholders are quoted in the Wall Street prints as talking as if they liked this. Of course there's no accounting for tastes. The Kennecott company will naturally increase its list of stockholders.

Some Prodigious War Wastes in Minor Items

High-explosive shells, which according to the newspapers are being fired at the rate of 1,000,000 a day on some of the 100-mile battle fronts in Europe, are of forged steel, made hollow to contain the bursting charge of explosive, and the nose of the shell threaded, into which is later screwed the nose detonating fuse. Between the time the shell is completed ready for shipment and its fusing prior to the action in which it is required, this opening in the nose of the fuse is closed by a plug screwed in temporarily.

The British have been using a brass plug for this purpose. The 4½-in. high-explosive shell manufactured in Canada has a brass plug which weighs 10½ oz., is very carefully machined and threaded, and screws into the nose of the projectile easily by hand, but has a square recess in the top for the insertion of a square-end wrench in case it cannot be unscrewed by hand. In the absence of specifications or an analysis of this particular plug, it is not possible to say just how high-grade this particular brass is, but if it conforms to specifications for other war material it can be assumed to be of the very highest grade and therefore the most costly. When the shells are fused in the battle area, these plugs are taken out and thrown away and are a total loss. If 1,000,000 of them were thrown away in one engagement in one day, some idea can be formed of the prodigous waste of war, so far as this item of copper and zinc is concerned. This of course is by no means the only use of copper and zinc in ammunition or for that matter on the explosive shell itself. The same shell that has this nose plug wasted has a copper rotating band near its base and has a time detonating fuse in its nose, both of which are converted into fragments on the explosion of the shell.

These same plugs when used for Russian shells are made of zinc. Information is not at hand about the grade required or specified for this purpose, but in any event the cost is excessive and the waste and loss complete.

There is no valid reason for making these temporary plugs of the most expensive material available, and evidently this has dawned upon those at the head of the munitions manufacturing department in England, because wood plugs are now being used for this purpose in place of the more expensive metals. Recently a manufacturer of war material was approached for a bid on a large number of these nose plugs. His figure, scaled down to the minimum, was more than a million dollars. This price being unsatisfactory to the representative of the foreign purchaser, the bidder made an alternative figure, which was less than $^1/_{100}$ of the first, if he were allowed to make the plugs out of wood. The turning of these plugs from wood and the cutting of a satisfactory thread on them is said to be one of the most difficult manufacturing details, but they are now being turned out and used and, so far as is known, with perfectly satisfactory results.

We have it from an authoritative source, that one reason why the Russian supply of ammunition was so slow in coming forward was because, prior to the exigencies of the recent campaigns, the Russian specifications required that all of their projectiles be nickel-plated, and neither the time nor the nickel was available for fulfilling these requirements on the vast number of shells that were being expended on the battle front. Nickel-plating the projectile of course reduces the wind resistance during its flight and therefore increases both its range and penetration, but with the modern grinding machine it is probable that nickel-plating the projectile does not gain any advantage over proper grinding and polishing, which are now done so cheaply and efficiently by United States manufacturers.

When these time fuses, which are very delicate pieces of mechanism, are manufactured and shipped, it is necessary to have them protected from moisture and dirt and dust. This is accomplished by covering them with a veil of tin-foil, which is wiped over the conical fuse. These veils are peeled off and thrown away when the fuse is put in the shell.

There was in the market recently an order for 25,000,000 fuses for the Russian government. The bidders were unable to find sufficient supplies of tin-foil, or the sources of such supply, to fill this order, and after a great deal of haggling, they succeeded in getting the specifications changed, substituting for tin-foil a lead-foil tinned on both sides, and by this means succeeded in providing sources for war material for the coverings required. This order of 25,000,000 was only a small part of the total order in hand, to be placed at that time.

This gives another idea of the prodigious waste of the less common and semi-rare metals in this war, and in both cases these wastes are minor items.

Mr. Manning is already showing in his conducting of the Bureau of Mines his earnest desire to live up to the traditions of Doctor Holmes. The guiding spirit is to make the bureau a useful thing to the mining industry and to keep in close touch with the men engaged in that industry in order to help in solving their problems. There is no policy of aloofness in this bureau, but rather the idea that mining men who visit Washington are welcome and that it is a good thing to talk matters over. This is of course just as it ought to be.

Liquidation Plan, Guggenheim Exploration Company

The Guggenheim Exploration Co. sent out a circular letter to its stockholders on Nov. 23, giving its liquidation plan. The letter, which is signed C. K. Lipman, the secretary, reads in part as follows:

For some time the directors have had under consideration the advisability of liquidating the business of the company and of distributing its assets among the stockholders. It is believed that the present is an opportune time for accomplishing that purpose. The most valuable single investment of the company consists of 404,504 shares of the capital stock of the Utah Copper Co. The directors deem it impracticable to dispose of this large block of stock in the open market at its fair value, and they consider it unwise to distribute it among the stockholders under conditions likely to result in a substantial shrinkage in values, to the injury of all concerned.

An opportunity has now presented itself which will enable the company to sell these shares to the Kennecott Copper Corporation on terms that will obviate these difficulties. It is proposed that the latter corporation shall purchase this entire block of Utah Copper Co. stock by giving in exchange therefor 1½ shares of its own stock for each share. The Kennecott Copper Corporation is perfecting arrangements with a syndicate which will purchase the requisite number of shares of the Kennecott Copper Corporation received by the Guggenheim company, whereby the stockholders will be enabled to elect whether they desire their proportions of the proceeds of the sale of this block of stock to be distributed to them in the shares of the Kennecott Copper Corporation or in cash at the rate of $75 per share for the stock of the Utah Copper Co. so sold.

The Kennecott Copper Corporation was organized on Apr. 29, 1915, under the laws of the State of New York. It has issued 720,000 shares of stock, without nominal or par value. Its present capital is fixed at $6,000,000. On May 27, 1915, it acquired the mining claims and property in Alaska known as the Kennecott mines, and shortly thereafter there was conveyed to it the mining property in Alaska formerly belonging to the Beatson Copper Co. These constitute copper producing properties upon which extensive valuable mineral deposits have been developed. The extraction of ore has been in progress on these properties in constantly increasing volume for several years past. The Kennecott Copper Corporation has now outstanding an issue of $10,000,000 first-mortgage 6% 10-year gold bonds, convertible into stock in the ratio of 40 shares of stock for each $1,000 bond. It has no floating debt except for current liabilities and for advances made against copper already sold.

The Kennecott Copper Corporation proposes, if it can do so on fair terms, to acquire additional properties and property rights, and to that end contemplates an increase of the number of its shares, which are to be issued without nominal or par value, from 720,000 to 3,000,000 shares, and of its capital from $6,000,000 to $15,000,000. The 2,280,000 of new shares are intended to be devoted to the following purposes, to the extent stated:

1. For the purchase of the 404,504 shares of Utah Copper stock owned by the Exploration company, 606,756 shares.
2. For the purchase from the respective owners thereof the shares of stock, convertible bonds and convertible debentures of the Braden Copper Mines Co., 800,000 shares.
3. For the purchase from the Alaska Syndicate of 48,174 shares of the capital stock of the Copper River & Northwestern Ry. Co., of the par value of $100 each, being its entire outstanding capital stock, of $23,020,000 par value of the 5% 50-year gold bonds of said railway company, being all of its outstanding bonds, and of 13,000 shares of the capital stock of the Alaska Steamship Co., of the par value of $100 each, out of a total authorized outstanding capital stock of 30,000 shares, 200,000 shares.
4. For the retirement of the $10,000,000 of convertible bonds of the Kennecott Copper Corporation, 400,000 shares.
5. For the compensation to be paid to an underwriting syndicate in consideration of the services rendered by it to the Kennecott Copper Corporation to meet the cash requirements of the proposed plan, which involves alternative offers of cash to the holders of the securities mentioned in the above subdivisions (1), (2) and (4), 65,000 shares. Total, 2,071,756 shares.

The remaining 208,244 shares of new stock and such of the shares above specified as may not be used for the purposes indicated will be available for the general corporate purposes of the Kennecott Copper Corporation.

The Messrs. Guggenheim, who are officers and directors of your company, are the owners of large holdings of the stock, bonds and debentures of the Braden Copper Mines Co. and of the stock and bonds of the Kennecott Copper Corporation. They are also members of the Alaska Syndicate, and as such are largely interested in the securities which the Kennecott Copper Corporation proposes to purchase from that syndicate and in the shares of stock of Kennecott Copper Corporation owned by such syndicate. Messrs. J. P. Morgan & Co. are likewise the holders of large amounts of the bonds of the Kennecott Copper Corporation, and are members of the Alaska Syndicate. That firm, as well as the Messrs. Guggenheim, and the directors of some or all of the corporations herein named, may become subscribers to the underwriting syndicate, when organized, and participate in its compensation.

Upon the consummation of this proposed sale of the shares of the Utah Copper Co., it is the present purpose of your directors, while retaining in the corporate treasury property exceeding in value the capital stock of your company, to make a distribution of a portion of its assets among its stockholders, as follows:

a. The proceeds of the Utah Copper Co. stock, by paying to such stockholders as shall elect to take their proportionate share of such proceeds in cash, $36.38⅓ in cash for each share of the Guggenheim Exploration Co. and to such stockholders as shall elect to accept shares of stock in the Kennecott Copper Corporation 72.77% of a share of the stock of the latter company for each share of the stock of the Guggenheim Exploration Co. held.

b. 97,750 shares of the capital stock of the Chino Copper Co., by transferring to each stockholder of the Guggenheim Exploration Co., 11.72% of a share of Chino stock for each share of the stock of the Guggenheim Exploration Co.

c. 69,500 shares of the common stock of the American Smelting and Refining Co., by transferring to each stockholder of the Guggenheim Exploration Co. of 8.33% of a share of common stock of the Smelting Company for each share of stock of the Guggenheim Exploration Co.

d. 154,300 shares of the capital stock of the Ray Consolidated Copper Co., by transferring to each stockholder of the Guggenheim Exploration Co. 18.50% of a share of the stock of the Ray company for each share of the stock of the Guggenheim Exploration Co.

Pan-American Scientific Congress

We are requested by the authorities in charge of this congress to announce that in addition to the general topics described in the preliminary program, issue of Apr. 15, the executive committee of the Second Pan-American Scientific Congress, which is to meet in Washington Dec. 27, 1915, to Jan. 8, 1916, has authorized the following important special topics, which will be discussed in a series of Pan-American conferences, a conference on each topic:

Mining—The mining law of each country and the changes that may be made to aid the development of mineral resources. History of the mining industry in each country with reference to the beginnings of that industry. The development of the Patio process. Bibliography of mining.

Metallurgy—Present methods of concentrating ores and the development of concentration methods.

International relations in the exchange of ores and metals. Bibliography of metallurgy:

A and B. Mining and Metallurgy—Development of hydroelectric power for mining and metallurgy, the amount probably available, and specific benefits from its utilization.

C. Economic Geology—The relation of geological work to the development of the country. A bibliography of economic geology.

D. Applied Chemistry—Natural and artificial nitrates; the present status and the outlook for these industries.

Safety Last

Pumping a man full of compressed air is still considered a joke by some people. Besides the case recently reported by the *Journal*, a worker at the Midvale Steel Works in Pennsylvania was subjected by two facetious fellow workmen, to an air hose containing air at a pressure of 80 lb. per sq.in. Immediate injury was not discovered, but soon after the man was suddenly taken ill while at work. At the hospital it was discovered that almost every internal organ had been ruptured by the air pressure, and it is not expected that the man can live. The fool-killer is a long way behind in his work.

Revision of Mining Laws

The Council of the Mining and Metallurgical Society of America—at the invitation, and under the auspices, of which a convention of mining men is to be held in Washington, D. C., on Dec. 16, to urge upon Congress the desire of the mining industry that the mining laws of the United States be revised—requests us to publish the following rules for the conduct of this convention, adopted at its meeting on Nov. 18:

The meeting to comprise three sessions, the first beginning at 10 a.m., the second at 2 p.m. and the third at 8:30 p.m.

The meeting to be organized with the president of the Mining and Metallurgical Society in the chair. The presiding officers in the several sessions to be the presidents of the M. M. S. A., the American Institute of Mining Engineers and the American Mining Congress, or representatives of those organizations.

A committee on credentials, three members, to be named by the Mining and Metallurgical Society of America.

The several sessions to be open to all persons interested in the mining industry, but the right of voting to be limited to accredited delegates and other persons especially invited.

Credentials to be: (1) Membership in the societies invited; (2) Representatives, one each, of chambers of commerce especially invited. Representatives, one each, of operating mines in the United States, provided that any such mines have no representation through membership in a society, or otherwise. Representation in all cases to be limited to citizens of the United States. Credentials to be passed upon by the committee on credentials, whose decision will be final.

A committee on rules, three members, to be appointed by the chairman.

A committee on resolutions, five members, to be appointed by the chairman.

All resolutions to be submitted to the committee on resolutions.

The committee on rules to have the right to make provisions limiting and concluding debates, if necessary.

We are further informed that the outlook is for a large and representative attendance. Persons attending the meeting are requested to register in the record book that will be provided for the purpose. Official headquarters will be in the Raleigh Hotel; registration in the United States Bureau of Mines; meetings in the Auditorium of the United States National Museum.

All persons expecting to attend the meeting are requested to notify F. F. Sharpless, secretary, Mining and Metallurgical Society of America, 52 Broadway, New York, as soon as possible. This is particularly important in the case of persons going from New York, in order that adequate sleeping-car accommodations may be provided.

Cyaniding in Closed Vessels

Recent discussion among cyanide metallurgists on the gold fields of South Africa has tended toward the saving of cyanide by carrying out the process in closed vessels. According to the *South African Mining Journal,* Sept. 25, 1915, in a paper presented to the Chemical, Metallurgical and Mining Society of South Africa by H. A. White, it was indicated that the average consumption of cyanide was 0.4 lb. per ton of ore treated, while zinc consumption was 0.32 lb. According to this, the annual requirement of sodium cyanide on the Rand is therefore about 5,000 tons, and it was said that, owing to its high price at the present time, any method of saving cyanide would be a distinct economy.

While efforts have been made recently to reduce the cyanide consumed, any actual reduction of consumption has been more than counterbalanced by a consequent loss of gold. H. M. Leslie believes that more definite beneficial results may be obtained through what he calls a "closed system" of cyanide treatment, which is in effect the carrying out of the process in closed vessels, so that there shall be no loss by evaporation.

Laboratory experiments have been carried out, and a considerable variety of information has been acquired, all of which tends to show that the loss by evaporation is great and that some steps should be taken to avoid it. Some authorities go even so far as to believe that the possible saving by using closed vessels may reach as much as 30% of the total now consumed. The matter will be further discussed, and a trial will be made to see just what can be done with the suggestion.

A New Flotation Experiment

SALT LAKE CORRESPONDENCE

A 25-ton experimental flotation plant employing the Fields process is being installed at the Ohio Copper Co.'s mill at Lark, under the direction of L. M. Walton, engineer for the Fields Electrical Flotation Co. This plant is being installed by John D. Fields and Irwin McNiece, who believe it will be of benefit to the General Exploration Co., now operating the Ohio Copper property under lease, and if it is successful a larger plant will be installed.

The recovery at the Ohio Copper mill has been only 64 or 65%, and if the Fields process is successful it will be used to treat the accumulated tailings, which include a 3,000,000-ton slime pile which carries about 0.8% copper. The 25-ton experimental plant is being installed in the western part of the mill, where it can cut in on any part of the feed. Experiments will be started first on the slime pile.

In a general way the process combines flotation and leaching and appears to be adapted to the handling of partly oxidized copper ores. Concentrates and electrolytic copper are produced. The crushed ore or tailings are placed in a cell with water to which a little sulphuric has been added, and agitated by air under 50 to 75 lb. pressure. Electric current, at from 10 to 25 volts and amperes depending on the size of the cell, is passed through the solution between copper electrodes. The current breaks down the water into hydrogen and oxygen, and these gases assist in the flotation of the sulphide particles, which are skimmed off. The oxidized portion of the ore is dissolved and deposited as electrolytic copper. The cost of treatment by this process, as indicated by experiments carried on at Maxville, Mont., on 1.57% copper ore, was approximately $1.25 per ton of material treated. A recovery of 92% was made. It is expected to have the experimental plant ready by the first or second week in December.

Canvass of Belgium's Metals

The Havas correspondent at Geneva, according to the New York *Times,* says that the German authorities at Ghent, Bruges, Mont. St. Amand, and Ledeberg have ordered by poster that all industrial establishments must declare how much copper, brass, and bronze they have, and in what forms. The directors of the industries are obliged to declare all old copper and extra pieces. The penalty for inexact or incomplete declarations is a fine of 20,000 marks, or imprisonment.

PERSONALS

Alfred Quimby, who is operating a gold mine in Guatemala, is visiting New York.

E. J. Collins, of Duluth, is in the Cobalt and Porcupine districts of Ontario on a trip of investigation.

Kirby Thomas has moved his office from 43 Exchange Place to Room 2744, No. 120 Broadway, New York.

Charles A. Banks, of the Jewel-Denero Mines, Ltd., and the Idaho-Alamo mines, both of British Columbia, is on his way to London.

Benjamin F. Tibby has opened a laboratory for microscopic analyses of rocks and ores at 419 Judge Building, Salt Lake City, Utah.

W. G. Norrie, mining engineer, lately of Vancouver, has been appointed manager of the Silver Standard mine at New Hazelton, British Columbia.

The Lehigh Portland Cement Co. announces the naming of Harold M. Scott as assistant secretary and the appointment of B. H. Rader as western sales manager.

E. Downie, president of the American Security and Investment Co. of Duluth, is in the Cobalt district in Ontario in reference to some projected operations there.

Charles W. Newton, general superintendent of the Consolidated Interstate Callahan Mining Co., Wallace, Idaho, was in Butte last week on business for the company.

J. G. McNulty returned to New York after several weeks spent examining pyrite deposits in Vermont, and has now gone to examine a copper property west of Sudbury.

Garnett Alfred Joslin, recently appointed mining engineer for the Ray Consolidated Copper Co., at Ray, Ariz., was married Nov. 9 to Miss Jessie E. Heber, of Los Angeles.

E. E. Kirkland, of Rome, Georgia, is opening a deposit of kaolin on his property near Lindale station. Several cars have been shipped recently and equipment will be installed.

Walter O. Snelling, formerly of Pittsburgh, Penn., has brought property in Long Island City, N. Y., on which he proposes building a large laboratory for chemical research.

W. W. Leck, superintendent of the merchant mill department of the Pennsylvania Steel Co.'s plant at Steelton, Penn., has been made superintendent of all the Steelton rolling mills.

R. J. Johnston, former assistant to the superintendent of the Donora plant of the American Steel and Wire Co. has been appointed superintendent of the zinc works of the company at Donora.

Frank L. Dalas, formerly chief electrician of the International Smelter Co., Miami, Ariz., has joined the electrical and mechanical department of the Youngstown Sheet and Tube Co., Youngstown, Ohio.

C. A. Buck, vice-president Bethlehem Steel Co., returned recently from Chile, where he has spent some months in the supervision of the new construction in connection with the company's Tofo iron mines.

Dr. S. J. Schofield, of Kingston, Ont., a graduate of Queens University and lately with the Canadian Geological Survey, has been appointed professor of geology and mineralogy in the University of British Columbia.

Gerald G. Dobbs, formerly chief engineer, ore mines and quarries, Southern District, Republic Iron and Steel Co., has been appointed superintendent of the Raimund Mining Division for the same company at Bessemer, Alabama.

E. V. Bray, vice-president A. L. Young Machinery Co., sailed from San Francisco on Nov. 20 for Celebes, Dutch East Indies, where he will design and construct a milling plant for the Minto concession of the Bolong Mongondou Company.

Alexander W. Behr, vice-president of the Russian-American Chamber of Commerce, Moscow, is now in this country in the interest of closer trade relations between Russia and the United States. His address is the Plaza, New York.

E. M. Hamilton, F. A. Beauchamp and S. E. Woodworth announce that they have become associated as metallurgical engineers under the firm name of Hamilton, Beauchamp, Woodworth, Inc., with offices and testing laboratory at 419 the Embarcadero, San Francisco, Calif

J. D. Mooney, for several years in charge of the sales of the mechanical rubber goods division of the B. F. Goodrich Co., Akron, Ohio, has become associated with the Hyatt Roller Bearing Co., Harrison, N. J. Prior to Mr. Mooney's engineering-sales experience he was an associate editor of the "American Machinist."

C. H. Williams, former assistant superintendent of the Schoenberger steel works of the American Steel and Wire Co. at Pittsburgh, has been appointed assistant to the superintendent of the plant at Donora. He has been succeeded by William Pickford, formerly superintendent of the bessemer department of the Schoenberger works.

OBITUARY

Joseph G. Hendrickson died at his home in Philadelphia, Nov. 4, after a short illness, aged 69 years. He was the founder of the Ajax Metal Co., which was established in 1880. He retired as president of the company a little over a year ago, and since then has been chairman of the board, also chairman of the board of the Ajax Metal Co. of the South, Birmingham, Ala., and president of the Ajax Lead Coating Co. He was a member of the Union League of Philadelphia.

William Carmichael died at Biwabik, Minn., Nov. 12, aged 69 years. He was born in Scotland and came to this country when a boy with his parents, who settled at Bruce Mines in Canada. In 1869 he went to Minnesota, settling at Tower on the Vermilion range. When the Mesabi range was opened he went to Hibbing, having risen to be mine captain. He was superintendent of the Rust Mine near Hibbing for a time, but in 1897 went to Biwabik where he was superintendent of the Duluth and McKinley mines. Later the Oliver Iron Mining Co. added the Graham and Weed mines at Mesaba to his charge. He was considered one of the foremost mining men on the Mesabi.

SOCIETIES

Society of Chemical Industry—The regular meeting of the New York section was held at Rumford Hall, New York, Nov. 19. The subject for the evening was "Industrial Chemical Research" and the program included addresses by G. R. Fonda, C. F. Burgess, R. F. Bacon and W. H. Walker.

Mackay School of Mines—The second session of the Prospectors' Short Course at the Mackay School of Mines of the University of Nevada will be held from Jan. 30 to Feb. 26, 1916. The work of the course will include both lectures and laboratory exercises, and the subjects taken up will be prospecting, assaying, mineralogy, geology, prime movers, chemistry, hygiene, sanitation, first aid to the injured, and mining law. In addition to these regular courses there will be a number of special lectures upon subjects of interest to the prospector. In the short time available it will be impossible to cover in detail any of the subjects taught, but an attempt will be made to acquaint the members of the class with as many practical points connected with these subjects as possible. This course is designed primarily to aid the prospecters of Nevada, but is open to residents of other states. Those who desire to attend should present themselves at the office of the Registrar in Morrill Hall, Reno, Jan. 30, and register. No charges will be made for instruction, but a fee of $5 will be collected to cover in part the cost of supplies used during the course.

INDUSTRIAL NEWS

The American Car and Ship Hardware Manufacturing Co., general offices and works, New Castle, Penn., is making large additions to its present plant.

The Bayard Chemical Co. is equipping a plant at Edgar Station, Woodbridge, N. J., for the manufacture of phenol, salicylic acid and a general line of pharmaceutical chemicals. Post office address is Woodbridge, N. J.

E. E. White, agent of the Mass patent drill hole compass, announces that 12 of these compasses have been rented to prominent exploring companies and drill contractors in the United States, Canada and Russia and are proving very successful.

The Homestead Valve Manufacturing Co., Homestead, Penn., is manufacturing an angle-type blow-off valve, to be used in connection with its plug cock, where a double blow-off arrangement is desired on steam boiler blow-off lines. The body of the "Hovalco" valve is of semi-steel, and the seat and disk are made of Monel metal. The valve is designed for 250-lb. pressure in 1¼ to 3-in. sizes and with screwed and flanged body.

Editorial Correspondence

SAN FRANCISCO—Nov. 17

The State Highway is Completed from Yreka to Hornbrook. The next advance will be to extend the road to the Oregon state line. Yreka is connected by a branch railroad to Montague, connecting with the Southern Pacific. The situation of Yreka in relation to the mining interests of the county is such that the mining men would be greatly benefited by good roads, in the building of which they should be aided by the State Highway Commission. The U. S. Steel Corporation is reported to be interested in manganese deposits near Sawyers Bar, but unless the wagon road from Etna to Forks of Salmon is widened and otherwise improved, or a new road is built following the trail to Orleans, there will be small prospect of developing the manganese. These improvements would permit transportation of ore by way of Etna and Yreka, or by Orleans to tidewater. But Siskiyou County and the wideawake towns should not wait for the Highway Commission to act in their behalf. The development of mines in Siskiyou County depends very largely upon good roads, and good roads depends very largely upon good citizens. Siskiyou County has the good citizens and should have the good roads.

The Dutch-Sweeney-App Mines in Tuolumne County, recently taken over by W. J. Loring, will be financed by American money, the Bewick, Moreing & Co. interests taking no part in the enterprise as a corporation or firm. Mr. Loring states that it is not at present possible to take British money out of the Empire and invest it in American mines or other enterprises without the consent of government. So he has interested Eastern investors in the exploration and development of this property. The three mines adjoin and for the sake of economical operation should have been worked under one management from the beginning of their productive period. The Dutch was developed into a good producer three or four years ago by C. H. Segerstrom, who installed modern machinery and extended development into the Sweeney ground. He got the property on a paying basis and would have undertaken to place the App on the same basis if he could have obtained the mine or secured control. Captain Nevills had numerous chances to sell the App, but about the time the proposed purchasers were ready to act the captain jumped the traces. He was a money-making miner and grew rich and was often broke. Always a hard man to deal with, the mine investors with the money and the ability to mine by modern methods concluded they would have to wait for Captain Nevills to die before undertaking to relieve him of the operation of paying mines which he was handling by early-day methods. Captain Nevills obliged them. He died, and the properties in Tuolumne and Amador Counties went into the hands of creditors. Then the chief creditor died. In the past year the Melones mine interests took over the Dutch-Sweeney, and it is probable the same interests would have considered the App in good time. Now that the three properties are in the hands of Mr. Loring, with Albert Burch in the position of manager for Bewick, Moreing & Co. interests in Amador and Eldorado Counties, the effect of British activity in the development of California gold mines will in a short time become quite evident, even if the company must now depend largely upon American investors. The showing made by the Plymouth Consolidated in Amador County under the management of Mr. Burch and the superintendency of Mr. Parks, and the active preparation at the Montezuma in Eldorado County and now the undertaking of the operation of these properties in Tuolumne County is proof enough that there is some inducement held out by the quality of the properties taken hold of. California has other mines that stand in the same need of money and men, and only await the application of modern methods to put them again in the producing class.

BUTTE—Nov. 18

The Montana Power Co. completed another of its many hydro installations. This time it is the Volta plant, situated 11 mi. northeast of Great Falls at the Big Falls of the Missouri River. This plant has a capacity of 90,000 hp., of which 61,600 hp. is now available. The plant will furnish the additional power required for the operation of the first division of the Milwaukee road and other large demands for power. The electrolytic refinery and other departments of the plant being installed by the Anaconda company at Great Falls will be ready for operation by Feb. 1, and a large amount of electric power will be needed there. The new equipment at the Washoe works at Anaconda is practically finished and the requirements there for additional power will likewise be large. Combined with the growth of the cities furnished with light and power by the Montana Power Co., this has made such an increase in the call for electric energy that all additions to the company power resources are practically taken in advance. The Volta plant is the largest of the company's hydro-electric plants. Its construction took three years. The equipment consists of four units of 15,000 hp. each and two smaller units of 800 hp. each, while provisions are made to bring the capacity of the plant up to 90,000 hp.

SALT LAKE CITY—Nov. 18

The Utah Iron and Steel Co., recently incorporated, has started operation at its plant at Midvale, and will supply iron and steel for building and manufacturing purposes. At present the plant is making round and square iron from ¼ in. to 4 in. in section, and flat material from 1x⅛ to 8x2 in. After the first of the year mine rails of 8, 12, 16, 18, 20, 25 and 30 lb. per yard will be manufactured. Other equipment will soon be installed, including an openhearth furnace. It is expected to manufacture structural angles for heavy construction. At present concrete-reinforcing bars are being made. C. W. Whitley is president. The properties and business formerly conducted by the Silver Bros. Iron Works Co. has been taken over by the Salt Lake Iron and Steel Co., which has assumed the obligations of the old company. The company announces that it is equipped to make nearly all kinds of iron, steel, brass and copper work, and asks to be allowed to bid on local iron and steel work, before orders are placed with eastern firms. A specialty is made of mining and especially designed machinery. O. C. Beebe is president.

Directors of the Utah Chapter of the American Mining Congress have passed a resolution, endorsing the resolutions of the Mining and Metallurgical Society of America, which has called a convention of mining men to be held in Washington, D. C., Dec. 16, for the purpose of urging upon Congress the necessity of revising the mineral-land laws affecting mining locations. Certain resolutions of the Mining and Metallurgical Society of America have been adopted by nearly unanimous vote and these the society will introduce at the meeting of Dec. 16. The subject is covered in the proceedings of the Society supplemental to Bulletin No. 87, Aug. 31, 1915, Volume 8, No. 8. Delegates of the Utah Chapter will be appointed for the purpose of presenting this resolution at the meeting on Dec. 16. The matter will also be taken up with Utah's Senators and Congressmen here with a view to getting them to take an active interest in the subject. The Secretary of the Mining and Metallurgical Society has been writing to the officials of mining companies here in Utah urging them to attend this convention or send representatives. R. C. Gemmell, governor of the Utah Chapter of the American Mining Congress, in a letter Nov. 16, to officials of Utah mining companies, outlining the above, says, he "realizes it is difficult for many of us here to get away for a trip of that kind, and therefore would respectfully suggest that if you cannot go yourself, you take the matter up with the officers of your company in the east, recommending that they send a representative of your company to the meeting." Mr. Gemmell states he has made such a suggestion to the New York officers of the Utah Copper Co. and adds that the meeting is a very important one and as many mining companies as possible should be represented.

WALLACE, IDAHO—Nov. 12

The Passing of the Ray-Jefferson into the control of the Days, reference to which is made in The Mining News of this issue, is a matter of deeper significance than appears on the surface. Prior to the meeting of the stockholders of the Ray-Jefferson in this city on Nov. 6, J. B. Beaty, secretary of and acting for the Consolidated Interstate-Callahan Co., who is also attorney for the American Metals Co., had offered 55c. per share for all or for a majority of the stock of the company, 1,500,000 shares, being on a basis of $825,000 for

the property, and it is learned from reliable sources that this offer was raised to practically a million when the stockholders met for the purpose of adding 500,000 shares to the capital stock of the company. This offer was met by Harry L. and Eugene R. Day, managers of the Federal and Hercules companies, respectively, both of whom were at the meeting, with the announcement that they stood ready to duplicate any offer that was made for any amount of the stock, and that as they had undertaken to finance the company, they felt that they should be given the preference by any stockholders who desired to sell. This talk won; the Interstate-Callahan offer was turned down, and the meeting proceeded to increase its capitalization by 500,000 shares which were turned over to the Days for their financial support and which gave them the control of the company. The Ray-Jefferson joins the Interstate-Callahan on the west and the development of both properties leads to no other conclusion than that the great orebodies of the latter extend into the former. The original Callahan ground lies next to the Ray-Jefferson. Reverting to the controversy within the Interstate-Callahan company over the appointment of a receiver and for the control of the company, which will engage the attention of the federal court at Coeur d'Alene the coming week, it will not be difficult to discover a motive for the control of the Ray-Jefferson outside of the actual value of the property. Since the appointment as receiver of the Interstate-Callahan by the state court, of Eugene R. Day, who is awaiting action by the federal court before taking charge of the property, the impression has grown that the ultimate purpose of the Callahan faction, which is trying to wrest control, is to dissolve the Consolidated company and combine the original Callahan property with the Ray-Jefferson. The receiver was already a large stockholder in Ray-Jefferson, had already guaranteed large financial support and the actual control of the property by him and his associates was clearly foreseen. That the Interstate-Callahan company believed this to be the purpose is plainly indicated by its eagerness to secure the Ray-Jefferson at almost any price, and it is equally evident that the Days, in meeting any offer, regarded it as essential to consummating their plans. In contending for the removal of the receiver in the federal court, it is expected that this phase of the case will be given much attention, in connection with the splendid financial condition of the Interstate-Callahan company, as showing that there was no valid ground for the application for a receiver and that it was not made in the interest of the stockholders of the company.

DEADWOOD, S. D.—Nov. 11

Lithium Ore is being Produced at three mines in the Keystone district, and several others are yielding these ores intermittently. The principal producing mines at present are the Hugo and Peerless, operated by H. Reinbold and the Bob Ingersoll, owned by C. H. Kamman. Amblygonite is the principal ore mined; it averages about 5% lithium and is worth $38 per ton, f.o.b. the Atlantic Seaboard, which is equivalent to about $28 a ton f.o.b. Keystone.

Wolframite is Being Produced on a large scale at the Wasp No. 2. Since the first of the year the production of ore, hand-sorted, averaging nearly 50% tungstic acid, has brought on the market over $100,000. Several hundred tons of medium-grade ore has been piled on the dump awaiting the construction of the contemplated concentrating unit of about 25 tons daily capacity. T. J. McGowan is taking out ore which will be shipped to McNish and Mills for concentration. The Black Hill Tungsten Co. is preparing to resume work in both mine and mill. Tungsten ores are also attracting attention around Hill City, where within the last few weeks, more than 50 locations have been filed on tungsten outcrops.

MORENCI, ARIZ.—Nov. 19

The Unionists Are Jealous of the Duncan tent colony, which is being added to by about 30 strike deserters daily. Although Gutierrez de Lara, organizer, denies the report that he advised the strikers, in public address, to consider means of breaking up the colony, he says that Duncan is the place for those who cannot distinguish between right and wrong; and that if supplication will not avail to bring them to a proper state of mind, a little physical force might turn the trick. The strike will be fought to a finish. Now is the time to "teach the mining companies their lesson" and to "stop, once and for all, assaults on organized labor." Everybody coming in is halted by strikers at the depot and his identity and business ascertained. The deputy sheriffs look on, or perhaps vouch for the "neutrality" of the visitor. Only 65 troops are still enjoying their outing here. Sunday train service between Morenci and Guthrie, Morenci So. Ry., and Sunday passenger service between Clifton and Hachita, N. M., A. & N. M. Ry., have been discontinued.

OATMAN, ARIZ.—Nov. 19

The Oatman District, which is enjoying such a substantial boom just now, is reached by wagon or automobile from Kingman, Ariz., about 25 mi. northeast, or about 12 mi. northeast from Needles Calif. Both points are on the Santa Fé. The old camp of Oatman is situated on rolling foot hills 10 mi. east of the Colorado River and is surrounded by mountains on the north, east and south sides. The population has increased from about 500, six months ago, to about 2,000 at present, and the dwellings now being erected have a look of permanency. The town enjoys a newspaper, ice plant, running water and other luxuries. Several properties in the district have changed hands recently, and much development work is being done. According to reports, there are any number of orebodies of all sizes and descriptions, assaying from $20 to $1,200 per ton. The Gold Roads mine, U. S. Smelting Co., ships about $65,000 gold bullion monthly, and the United Eastern has ore blocked out to the value of 8 or 10 million dollars. A few days ago the James mill at Secret Pass sent to Kingman a gold bar valued by the bank at about $850, the cleanup of only 105 hrs. run. The new slogan throughout the county is that "The greatest knocker in Mohave County is opportunity."

COBALT, ONT.—Nov. 20

Local Agitation for Coinage of a Small Cobalt Coin of 5c. denomination for Canadian circulation is being pushed, and some hope that England may also be induced to come into line on this financial innovation. It is argued that cobalt is as available for coins as nickel and it is hoped to have in circulation a distinctively Canadian coin which will be designated in the vernacular a "cobalt" in emulation of the ubiquitous and nimble American "nickel." Also there is the local motive of enlarging the market and uses for cobalt which is distinctively a Canadian product and which is found there in such superabundance.

The Future of the Silver Market is an ever present subject of discussion in this camp. When the war began all the "wise ones" predicted a rise in silver. Various reasons were advanced and high authorities were quoted to back the arguments. In fact, managements of the companies in the financial centers seemed to be of the same opinion as the local "wise ones," for several of the companies made arrangements to hold all silver for the expected great and immediate rise. After more than a year of very low market the "bull" argument is again to the front with the same reasons and some others based on the real or imagined financial status of the world as affected by the present prodigious expenditures of Europe. It is argued that Europe must go on a silver basis in order to meet the extraordinary conditions which have arisen or are likely to result from the war. The optimists have the floor for the time and the good behavior of the silver market for several weeks aids them. To the outsider the great concern about silver can be understood better than sympathized with. This camp produces silver for from 10c. to 25c. an ounce and while the extra cent or two on the selling price is interesting, it is not vital to the present or immediate future of the mining industry of Cobalt. Several of the strong companies have for some time been storing silver in the banks against the expected rise, which has resulted in a growing dissatisfaction among the stockholders who claim that the small gain so far evidenced is hardly an offset for the loss in interest, and anyway they would like their money for present opportunities. Already letters of protest are being sent to the managements by large stockholders. It remains to be seen whether the "wise ones" are as right now marketwise as they were a year ago. No doubt a strong rise in silver would result in a greatly enlarged production from the camp, for it is known that several of the large companies are not now pushing output to the limit and in fact recently several of them have curtailed mining operations presumably in hopes of a better market at some future time.

BALFATE (VIA TRUJILLO), HONDURAS—Nov. 8

The Discovery of Asphalt in Honduras, near Jutigalpa, was mentioned in a recent number of the "Journal," giving it as tributary to Amapalla as an outlet for the product, etc. As a matter of fact, it is tributary to Trujillo, on account of the shorter distance—approximately 180 mi. with a standard gauge railroad being built and well under way by the Truxillo R.R. Co., (Truxillo and Trujillo are one thing), which is heavily financed; Jutigalpa being the objective point, with Trujillo as the ocean terminal. This will open a rich mineral country, chiefly gold and copper; the latter exists in veins with vertical exposures in creek cañons of from 10 to 45 ft., and is rich ore, some assaying 42% copper with a gold content of $800 per ton. Some have been worked in a crude way. Most of the church bells in Olancho were cast with metal from this ore.

The Mining News

ARIZONA

Gila County

OLD DOMINION (Globe)—Production of Old Dominion smeltery for October was 2,700,000 lb. of copper, an increase of 400,000 lb. over September. Concentrator is handling daily about 100 tons of ore from Arizona Commercial and about 600 tons from other sources. Old Dominion mine is producing 900 to 1,000 tons of ore per day, and pumps are handling 5,000,000 gal. of water daily. The unwatering of Big Johnnie shaft is progressing satisfactorily.

Mohave County

LEXINGTON (Kingman)—Sinking of three-compartment shaft at Lexington mines to depth of 600 ft. will be started soon. Cross-cutting will begin at 600-ft. level.

Pima County

NEW CORNELIA COPPER (Ajo)—New railroad from mine at Ajo to Southern Pacific R.R. at Gila Bend will be completed Jan. 15.

Yavapai County

BAUMANN (Prescott)—Stockholders of Baumann Mines Co., St. Paul, Minn., men, contemplate extensive campaign of development work at mines. One-mile wagon road now being built to property.

PITTSBURGH (Briggs)—Work of developing Pittsburgh mine, situated on Castle Creek near Briggs, has been resumed by C. E. Champie. Has large quantity of rich ore blocked out and will soon begin making regular shipments.

ARKANSAS

Sebastian County

A NATURAL GAS WELL, sunk at Fort Smith, Ark., by Harry Kelly, at 2,300 ft., is yielding 15,000,000 cu.ft. of gas per day.

CALIFORNIA

Amador County

ZEILA (Jackson)—Reported that Kennedy Mining Co., which recently purchased this mine, will sink a new shaft for development and operation of orebody disclosed about year ago.

PLYMOUTH CONSOLIDATED (Plymouth)—Report of W. J. Loring, representing Bewick Moreing & Co., states that company expended $830,000 in development and installation up to time milling of ore began. Form Aug. 1, 1914, to Oct. 1, 1915, gross production has been $686,074; surplus over all expenses being $218,030. Mine is equipped with 30 stamps but only 25 have operated. In period named 141,623 tons of ore were treated; average duty per stamp at present time is about 11 tons, and recovery, fraction under 90%. Total cost including development has run from $6,000 to $9,000 per month, making per ton cost under $2.90.

Butte County

ZENITH IRON (Forbestown)—Reported that men representing U. S. Steel Corporation have undertaken development of this iron and chrome deposit. Ore is being hauled to Oroville by motor truck and shipped to Pennsylvania by Western Pacific.

WHITLOCK (Chico)—Shipment of 22 tons of sacked ore to Selby first ore shipment from Chico for several years. Mine is situated on Butte Creek; owned by Frank Whitlock, K. D. Crowder and others. Ore hauled distance of about 15 mi. to Chico in motor trucks.

Calaveras County

CALAVERAS COPPER (Copperopolis)—On No. 4 level 15-ft. body of ore in hanging wall reported to assay more than 8% copper. Besides ore going to concentrator, some shipments are being made.

GREEN MOUNTAIN (Angels Camp)—J. B. McGuire and J. Ivers operating under lease on this gravel mine in Chili Gulch are taking out pillars left in old workings and receiving good returns. Some of gravel yielded at rate of $50 per car. Gold is coarse.

Eldorado County

EUREKA SLATE (Placerville)—W. J. Dingee reported to have installation of new machinery near completion. Old machinery is being overhauled and tested aërial tramway has been repaired and will be extended to railroad. Production of slate is expected to be resumed soon.

Inyo County

CUSTER (Darwin)—J. H. Thorndike has resumed work. The shaft is being straightened and preparations are being made for active development.

DARWIN DEVELOPMENT CO. (Darwin)—Knox 10-ton tractor has been received and will be used in hauling the ore 24 mi. to Keeler, nearest railroad shipping point. Company is operating under lease and purchase option.

Kern County

GENERAL PETROLEUM (Taft)—New pipe line in north Midway in course of construction, with 100 men employed and 100 to be added as soon as work is in shape to handle them. Pipe line will be 26 mi. long.

YELLOW ASTER (Randsburg)—Both mills, with total of 130 stamps, crushing about 300 tons of ore per day. Earnings for first eight months of 1915 totaled $305,584. Total costs of operation, $199,068; surplus, $106,516; dividends for period, $11,000.

Monterey County

PATRIQUEN (Parkfield)—Small retort being operated, producing 20 flasks of quicksilver per month. Shipments go out by way of San Miguela.

San Bernardino County

TRONA POTASH (Trona)—Large amount of machinery received and new surface buildings erected preparatory to increasing operations at Searles Lake. Refining plant at San Pedro near Los Angeles will be installed.

Shasta County

MENZEL (Redding)—A. Meagher and Frank D. Barbet are reopening this mine on Flat Creek and have 200 tons of ore ready for shipment to Mammoth smeltery at Kennett.

MAMMOTH (Kennett)—A 2-unit zinc-oxide plant is being installed to be operated in conjunction with baghouse, in further reducing fumes. Drill sharpeners are being installed at Sutro and Friday-Lowden. An air-pipe line is being laid from Mammoth compressors to Friday-Lowden, distance of 4,000 ft. Tunnel to be driven from this point will tap Mammoth 500 ft. below present No. 5 tunnel, which is main working level.

Tuolumne County

DUTCH-SWEENEY and APP (Jamestown)—W. J. Loring, principal partner of Bewick Moreing & Co., has interested American investors and taken over these 2 mines. Dutch-Sweeney was recently acquired by Melones interests, and App has been idle for about 2 years, being closed down prior to death of Capt. Nevills, original owner.

COLORADO

Clear Creek County

PRODUCTION DURING THE MONTH OF OCTOBER from the mines adjacent to Idaho Springs amounted to $48,200. Of this amount, $30,200 is represented by 87 carloads, or 2,175 tons averaging $14 a ton, shipped through the Chamberlain Ore Co. The balance of $18,000, is represented by bullion from the Argo mill to the Mint at Denver. The production is about $2,500 or 5½% more than for the same month last year.

CAPITAL MINING AND TUNNEL (Georgetown)—Adit which is being advanced on Aetna vein has opened 12-in. vein of high-grade ore, assaying 1 oz. gold, 40 oz. silver and 25% lead.

GEORGETOWN TUNNEL AND MINING (Georgetown)—This development tunnel is to be advanced an additional 100 ft. under contract awarded to Chas. Jones and Edward Wing. John Keating, of Georgetown is manager.

ALMADEN MINES CO. (Idaho Springs)—Entire property of this company, situated in Lower Fall River Mining District, has been sold to satisfy judgment amounting to $27,620. Property was purchased by George Neill, of Topeka, Kan., and J. A. Greenfield, of Bellaire, Ohio. Active development of mines will be resumed in near future.

Denver County

WESTERN CHEMICAL (Denver)—Continues to make large expenditures for increasing its manufacturing capacity. Business has increased markedly since withdrawal of competition by eastern manufacturers who are filling war orders. This company now sells more than 1,500 tons of sulphuric acid per month; product being derived from complex Colorado sulphide ores that are purchased at an average price of $12 per ton.

Teller County

BEQUA SAVAGE GOLD MINING CO. (Cripple Creek)—This is new incorporation organized to take over holdings of old company of same name. Directors for first year are J. S. Guyer, Jas. Yeomans, Albert Schumacher, J. T. Hawkins and Sarah Finegan. Property is located on eastern slope of Beacon Hill adjoining Gold Dollar, St. Thomas, Commonwealth and Little Nell properties. Campaign of development is under advisement.

SHOO FLY (Cripple Creek)—This property on southwestern slope of Womack Hill is being developed under lease by Hickman & Co. Old discovery shaft has been cleaned out and will be sunk to depth of 100 ft. Rich surface discovery, which was made about 50 ft. north of the shaft, will be developed through new shaft. Recent sampling of vein indicates high-grade ore. A 2½-ft. streak assays over 9 oz. gold for distance of 15 ft. along vein. Screenings from ore produced from surface openings assay 15 oz. gold. Western extension of Shoo Fly vein has been opened in Iowana property. Ground is included in Block 160 of Stratton Estate.

JERRY JOHNSON (Cripple Creek)—Property is being operated from 650-ft. level to surface by Caley Leasing Co. which is performing active development. Caley mill has been started and it is estimated that available low-grade ore in mine will keep plant busy for four or five years. Rich strikes have recently been made on 160-ft. and 550-ft. levels. Concentrates from mill are averaging about $28 a ton. Mine is being actively developed on 850-ft. level by Cripple Creek Deep Leasing Co. which controls ground below the 650-ft. level. Payable ore has been opened in new development. Since commencing operations this company has completed 275 ft. of crosscutting and drifting. Another crosscut will be started on 950-ft. level

IDAHO

Shoshone County

NATIONAL COPPER (Mullan)—Mill started Nov. 11, after much delay in getting equipment. It is reported that bins hold 12,000 tons of ore and mine is in condition to keep mill going at capacity, 500 tons, per day. Recent development has disclosed better grade of ore in drift from bottom 200-ft. shaft and also in upper workings, improvement being in both copper and silver.

COEUR D'ALENE ANTIMONY (Kellogg)—This company which took over old antimony property at mouth of Pine Creek is building mill, frame work of which is almost completed and much machinery on ground. Shipped one car that averaged 36% antimony and second car is in transit. Much ore in sight in mine, one shoot being 80 ft. long and 4 ft. wide. All ore will be milled and it is expected that shipping product of not less than 50% will be turned out.

COLONIAL MINING CO. (Kellogg)—Company, of which Watson and J. D. Beebe are controlling factors, was recently organized to take over Little Pittsburg property on Pine Creek. Contract let to Union Iron Works of Spokane for tram 1½ mi. long; to deliver ore at base of hill; tram is to be completed in 5 weeks. Ore will be hauled by team from end of tram to railway station, 7 mi. Company has ordered machinery for sorting plant and expects to ship 30 cars monthly of crude zinc ore.

RAY-JEFFERSON (Wallace)—Meeting of stockholders Nov. 6 increased capital stock from 1,500,000 shares, par value of 25c., to 2,000,000 same par. Additional stock taken by Harry L. and Eugene R. Day, manager of the Federal and Hercules companies, respectively, and gives them, with their former holdings, 850,000 shares, or practical control. Mill will be built on Beaver creek early in spring, and it is regarded as certain that railroad will be built from North Fork branch of the O.-W. R. & N. to Ray-Jefferson, distance of about 10 mi. Company owns 32 claims and large ore shoots have been developed on two veins, both lead and zinc.

INTERSTATE-CALLAHAN (Wallace)—Report of John A. Percival, president of the Interstate-Callahan company, for quarter ended Sept. 30, 1915, has been made public. Total receipts were $1,049,478; operating costs totaled $162,351 and improvements $23,935, leaving operating profit of $863,192. Tonnage mined was 29,021; shipments of crude ore and concentrate aggregated 15,443 tons—ratio of run-of-mine ore to shipping product of 1.879 to 1. Of crude lead ore 203 tons was shipped, assaying 19.54 oz. silver and 40.68% lead; of crude zinc ore, 2,506 tons, 49.01% zinc. Ore milled totaled 24,595 tons, 28.5% zinc. Concentrates produced were: Lead, 792 tons, 23.86 oz. silver, 53.33% lead; zinc, 11,942 tons, 48.66% zinc. Ratio of milling ore to total concentrates was 1.93 to 1. Total cost per ton of ore mined was $5.495, of which $3.389 represents cost of mining and $2.106 the cost of treating and shipping.

MICHIGAN

Copper

CALUMET & HECLA (Calumet)—Shipments of silver to United States Mint increasing steadily. The amount this month was $27,000.

NEW ARCADIAN (Houghton)—Third mill test showed 34 lb. of mineral per ton in 1,132 tons of rock. Showing is quite as good as two previous tests.

NEW BALTIC (Houghton)—Has operations well under way to reach Arcadian lode. Treasury is amply supplied with funds, $60,000 in all when last assessment is fully paid.

WHITE PINE (Ontonagon)—In addition to copper is finding considerable silver and some gold in its recoveries. Another important development is the realization that the shale carries commercial copper. When this property first opened and for the first few years of its underground opening work greatest difficulty was narrowness of rich standstone vein, bounded by shale. Shale does not run as high as sandstone in copper, but it does give a width of 30 ft. of profitable vein matter.

MINNESOTA

Cuyuna Range

ROWLEY (Barrows)—Electric pump installed and sinking will shortly be resumed.

CUYUNA-DULUTH (Ironton)—After idleness of over a year this company's Ironton shaft will shortly resume operations.

CRAFT (Crosby)—Drifting is progressing but no production will be shipped this season. The 40-acre tract immediately east of Craft has been optioned for lease on a 25c. royalty and 20,000-ton minimum. Grantees in transaction are not named.

CUYUNA-SULTANA (Ironton)—Soo Line now laying steel on spur to mine. If same is completed before navigation closes, the 6000-ton stockpile of manganiferous ore will be shipped. Daily production 200 tons. Mine and concentrator will be operated all winter.

Mesabi Range

LA RUE (Nashwauk)—Washing plant being thoroughly overhauled. It is planned to increase production to 300,000 tons next season.

Vermilion Range

SOUDAN (Tower)—Concrete foundations being laid for new steel shaft house, superseding present wooden one.

MISSOURI-KANSAS

NEW CENTURY (Galena, Kan.)—Has started up again after being shut down for few weeks making some improvements in plant. Installed new set of sludge tables to help handle slime that comes from fine sand in overflow from steam jigs, which formerly was carried off by water to supply pond. Is one of best equipped plants in district.

J. M. SHORT (Joplin, Mo.)—Has made an exceptionally good strike on his 10-acre lease on Banker land southeast of Joplin. At 145 ft. struck ore which assayed 29% zinc. Ore continues down to 165 level where it assays 19%, with same grade of ore in bottom of shaft. Will drill another hole or two and if they prove as good as first one, will build new plant to handle ore.

GRAND TOWER (Joplin, Mo.)—To build new concentrating plant on lease of 10 acres southwest of town. Plant will be 150 tons' capacity; run by electric power. Ground was worked several years ago, but shaft and ground caved in and ground was abandoned. New company has sunk new shaft; struck first ore at 65 ft. which continued down to 90-ft. level, giving 25-ft. face of good ore which assays from 10 to 20%.

MONTANA

Dawson County

NATURAL GAS NEAR GLENDIVE—It is reported that natural gas in commercial quantities was struck Nov. 17 in well, 11 mi. southwest of Glendive. Drill was sent to depth of 751 ft. and flow of gas showed pressure of 400 lbs. per sq.in. Two other wells will be drilled at once and gas piped to city where a franchise for its use has already been awarded.

Jefferson County

BOULDER MINING DISTRICT—Doctor Ironside, of Butte, who owns Shield property, 12 miles south of Boulder on Little Boulder River, is building concentrator. He has put up sawmill near mine to cut timber for mine and mill; expects to complete mill next spring. There is said to be fine showing of ore containing copper, silver and gold. Forty men are employed at property at present.

Lewis and Clark County

UNIONVILLE MINING DISTRICT—Reported that rich strike of gold quartz has just been made in an old tunnel at mouth of Arrastra gulch. Vein is declared to be 7 or 8 ft. wide and the ore to be free milling carrying from $50 to $75 of gold per ton. Mine is located 3 mi. above road to Unionville in neighborhood of East Spring Hill properties. Strike was made while doing assessment work.

Missoula County

RICHMOND (Saltese)—Shipments average one car of ore a week to British Columbia smelters. Ore carries 8 to 29% copper and $4 to $8 in gold. Construction of aërial tram postponed and wagon road is being built from Adair, 3 mi. from mine. Ore is now shipped by way of Saltese, 6 mi. from mine.

Silver Bow County

NORTH BUTTE (Butte)—Widows of eight of the 16 victims of the explosion at Granite Mountain shaft which occurred Oct. 19, applied for lump sum settlements of $4,000 each when they appeared before E. A. Spriggs, chairman of state accident board, at meeting held in Butte Nov. 11 to determine compensation. Board hesitates about giving lump sums because few of these women have had business experience, and it would defeat purposes of act for them to lose their compensation in short time. Compensation in all will amount close to $75,000. Injured men will not receive full compensation until their injuries are determined. In meantime they will receive $10 a week.

NEVADA

Mineral County

LUCKY BOY (Hawthorne)—A 600-ft. tunnel completed recently for haulageway and drainage. Upper workings 300 ft. above face of tunnel which is 1,200 ft. below original Lucky Boy shaft collar. Several leasers are working around 800-ft. level.

Nye County

TONOPAH ORE PRODUCTION for week ended Nov. 13 amounted to 9,189 tons, estimated value $191,362, compared with 10,343 tons week previous. The producers were: Tonopah Belmont, 2,887 tons; Tonopah Mining, 2,250; Tonopah Extension, 1,850; West End, 609; Jim Butler, 1,100; Halifax, 70; North Star, 53; and miscellaneous leasers, 370 tons.

Storey County

SIERRA NEVADA (Virginia)—Development on vein 2,500 level disclosed low-grade ore; 68 tons of ore saved averaging $11.42 per ton.

ANDES (Virginia)—Saved 15 cars of ore from stope above 175 level. Repairs to 250 level connecting with 250 level of Central has been started.

OPHIR (Virginia)—In Central tunnel 250 level disclosed 7 ft. good milling ore. Saved 359 cars of ore from stopes above north and south drifts; milled 312 tons.

MEXICAN (Virginia)—Sampling in west crosscut on 2,500 level and prospecting on 2,700 level. Winze on 2,700 level shows 3 ft. of vein matter in bottom; selected samples assay $50 per ton.

CROWN POINT-BELCHER (Gold Hill)—Saved 153 tons of mill rock from sill floor; north drift reopened to 130-ft. point; 86 cars mill rock saved; Jacket mill received 878 tons of dump rock and shipped bar of bullion.

UNION CONSOLIDATED (Virginia)—Extracted 105 tons of ore averaging $26.32 from south end of No. 3 stope on 2,500 level, and 56 cars of low grade in making room for timbers. Saved 50 tons of ore averaging $18.40 from raise in No. 1 stope. Top of raise in ore sampling $20 per ton.

NEW MEXICO

Grant County

J. T. OGLESBY (Pinos Altos)—Has arranged to finance custom mill for district. Plant will be erected on old Bell & Stephens mill site.

Lincoln County

WILD CAT LEASING (White Oaks)—North and South Homestake mines of the Wild Cat Leasing Co., and Old Abe mine, mills and water rights, also Miner's Cabin and Silver Cliff mines, were sold last week to Richard Wirhtman and associates, of New York, for $250,000. Edward Queen, formerly of the Wild Cat Leasing Co., will have charge of the properties. The new company will rush mining of tungsten ore, of which a carload was recently shipped that netted over $19,000.

PENNSYLVANIA

Allegheny County

PENNSYLVANIA SMELTING (Carnegie)—Day interests, identified with purchase of old smeltery at Northport, Wash., have announced purchase of refinery at Carnegie from Pennsylvania Smelting Co., and state that its capacity will be increased to take care of output of Northport plant.

SOUTH DAKOTA

Lawrence County

RATTLESNAKE JACK (Galena)—A chute of high-grade ore was encountered in the main workings. Two Wilfley tables are being installed in the mill and as soon as the Oliver filter is added the plant will resume operations.

Pennington County

BIG HIT (Keystone)—Shaft being unwatered and property undergoing repair for active development work.

INGERSOLL (Keystone)—Regular weekly shipments of a carload of spodumene are being made to the East.

COLUMBIA (Keystone)—At this property, financed by Supt. R. Blackstone, of Homestake Mining Co., shaft is to be sunk to the 200-ft mark, where further lateral work will be done. New shaft is 325 ft. from old shaft, which produced $100 ore. New shaft has disclosed ore; also found in crosscut on 100-ft. level.

TEXAS

Culberson County

HAZEL (Van Horn)—Is now being worked by Steele-Sutton-Steele Co., of Dallas. Last car shipped netted $125 per ton in silver and copper.

PECOS (Van Horn)—Which has been shipping copper ore for last six months, has been leased by P. B. Walker and associates, of El Paso and Mexico. They will start regular development at once and will sink 120-ft. shaft to depth of 200 ft., where they expect to find silver ore.

UTAH

Beaver County

CROFF (Milford)—Fifteen inches of silver-lead ore has been opened in bottom of Lucky Boy shaft, at this property in Lincoln mining district.

MOSCOW (Milford)—New electric hoist has been shipped and should be installed shortly. Cullen shaft is to be sunk 300 ft. deeper from 800 to the 1,100 level.

DAVIS LEASE (Beaver City)—A 30-ton mill test is being made on second-class ore from this lease at Fortuna. Ore is being hauled 10 mi. to Sheep Rock mill to be treated.

FORTUNA GOLD QUEEN (Beaver City)—Work at this property has been started under direction of R. N. Strickland. Material has been delivered for erection of mine buildings, etc.

LUMLEY & MOORE (Beaver City)—Joe Davis lease has opened ore running well in gold. Five and a half feet are exposed. Harris & McGillis lease on parallel vein has opened 12 ft. of ore.

MAJESTIC (Milford)—Last car shipped by this company from its Old Hickory mine in Rocky district, carried 3.85% copper and 2.2 oz. silver per ton. Work is being done from bottom of large open cut. Vein is 20 ft. wide.

Juab County

UTAH POWER AND LIGHT CO.'S CONSTRUCTION WORK on new substation, owned jointly by Eagle & Blue Bell and Chief Consolidated, is well under way. The transformers have arrived. An automatic voltage regulator is being installed.

EAGLE & BLUE BELL (Eureka)—Foundations for new 250-hp. hoist have been laid, and gallows frame is nearly finished. Much of electrical equipment has been delivered, and is being installed.

YANKEE CONSOLIDATED (Eureka)—Shipments from new strike have been started; these are high in silver. New tunnel is being driven to tap ore at greater depth, which will facilitate handling and allow for disposal of waste. About 125 ft. of work will be necessary to make connections with winze. New work has been started in southeastern part of ground where tunnel is being driven in search of Beck Tunnel vein. Shipments of high-grade zinc ore from old stopes being made by leasers.

Salt Lake County

WORK IN BIG COTTONWOOD is being done at the following properties: Reed's Peak, five men; Branborg, three men; East Carbonate, three men; Big Cottonwood Consolidated, five men; Tar Baby, four men; Price Mining, six men; Monte Cristo, six men; American Consolidated Copper, six men; Kennebec, three men; Cardiff, 115 men; Last Chance, two men; Thor & Venus, two men, total, 160 miners.

ALTA CONSOLIDATED (Alta)—Drifting has been started at 100-ft. point in winze sunk on Braine fissure.

PRICE MINING (Salt Lake)—Tunnel is in 120 ft., and still in heavy ground. Spiling and timbering is necessary. Property adjoins Cardiff in south fork of Big Cottonwood.

UTAH COPPER (Bingham)—Up to 30,000 and 31,000 tons of ore are being mined and milled daily. Of this Magna mill is handling about 20,000 tons and Arthur between 10,000 and 11,000 tons.

SELLS (Alta)—Ore has been opened from raise 70 ft. above tunnel level. This is thought to be downward extension of Skipper fissure, which produced ore from surface workings. Sells is being operated by A. O. Jacobson and associates, through main tunnel of South Hecla.

ALBION (Alta)—Eight carloads of silver-lead-copper ore, carrying gold, have been shipped by leasers since the middle of October. This comes from old Wellington workings. Ore occurs in strong vein 4 to 5 ft. between walls. Royalties from leasers are sufficient to pay operating and development expenses of company.

NEW ENGLAND GOLD AND COPPER (Bingham)—Suit has been filed in third district court by International Trust Co., of Boston, asking for receiver and foreclosure on this company's property. Action is based on default in interest on $390,000 bonds. Trust company, as trustee of mortgage and trust deed, has been requested by bondholders representing $373,300 to file action and bring about foreclosure. Interest due Feb. 1, 1914, was not paid; interest to date amounts to $46,800. Property consists of seven claims in south branch of Carr Fork, and adjoins Utah Copper and Last Chance claims. Recently operations have been carried on by leasers only.

Summit County

PARK CITY ORE SHIPMENTS for week ended Nov. 11 amounted to 2,156,224 lb. by four shippers. Heavy storms have interfered with ore hauling.

SILVER KING COALITION (Park City)—Working forces now amount to 300 men at mine and mill, as compared to 370 men before strike. Reorganization of force is in progress.

BIG FOUR EXPLORATION (Park City)—New mill at Atkinson is treating 250 tons of old tailing dumps daily. Plant is now in good running order, and efficiency has been greatly increased. Concentrates carrying up to 40% zinc being made.

VIRGINIA

Augusta County

CRIMORA MANGANESE CORPORATION (Crimora)—Has contracted with Ruggles-Coles Engineering Co., New York, for first unit of its new washing plant, which is to have capacity of 100 tons of washed ore in 10 hr. Mill will comprise Kennedy slugger-roll crusher, McLanahan-Stone log-washers and jigs and Stephens-Adamson conveyors and transmission machinery. Foundations are in and it is expected that mill will be ready in January. It is proposed to mine with Schofield-Burkett dragline excavators. W. L. Hogg, manager.

WASHINGTON

Stevens County

UNITED COPPER (Chewelah)—United Copper mine, 60 mi. north of Spokane, earned $4,423 net in September, according to official report of directors. Report states that profits for October will be considerably larger, as mine and mill were working at greatly reduced capacity in September; it is estimated that November earnings will be between $25,000 and $35,000. Mill has been increased by addition of 50 stamps, making 74 in all; plant now is operating at capacity, 235 tons of ore daily. "During the early months of the year we were endeavoring to adapt the new oil flotation process to saving the values from our concentrates," states President Conrad Wolfle, of Spokane. "This entailed considerable experimental work and necessitated tearing out our slime tables and installing the tanks and cells of the new system, as well as making exhaustive tests to ascertain the proper kind of oil required for our sulphide ores. It took some time to get the process down to a profitable working basis, but for several months our saving has ranged from 77 to 80%, which is as good as is being secured by any other plant in the northwest from a similar class of ore. The percentage of saving is being increased continually by further tests and improvements to the process."

CANADA

Ontario

ORE SHIPMENTS OVER THE T. & N. O. Ry., for October, were from: Cobalt proper, Beaver, 30 tons; Buffalo, 92; Cobalt Comet, 63; Coniagas, 32; Crown Reserve, 99; Kerr Lake, 57; La Rose, 37; McKinley-Darragh, 81; Mining Corporation of Canada, Cobalt Lake Mine, 216; Townsite City, 202; Nipissing, 103; Penn Canadian, 31; Peterson Lake, 141; Right of Way, 38; Temiskaming, 31; total, 1,311 tons; from New Liskeard, Casey Cobalt, 29; from Elk Lake, Miller Lake O'Brien, 23; from South Porcupine, Dome Lake, (gold) 31; Porphyry Hill, (gold) 20; from Porquis Junction, Alexo Mine (nickel), 799 tons.

CANADIAN COPPER (Sudbury)—Has given up option on copper property in West Shining Tree on which it was working.

TEMISKAMING (Cobalt)—Has declared 3% dividend; time of payment not being specified. It is 2½ years since company has paid dividend. There is large amount of cash on hand and ore reserves are estimated at about $250,000.

VIPOND (Porcupine)—With reference to rumors of dividend, President Ward states that while results of operations have been satisfactory, it would be premature to consider definite plans for dividend in immediate future. Report covering operations from Apr. 1 to Sept. 30 will be issued soon.

MOOSE MOUNTAIN IRON MINES (Sudbury)—Has been closed. This was largest attempt to work concentrating magnetic iron ores of Northern Ontario. Difficulty was experienced in getting satisfactory briquettes from fines. Over million dollars has been spent by MacKenzie & Mann, and Gates interests.

MANIGOTAGAN GOLD MINING AND DEVELOPMENT CO. (Toronto)—New company formed by Toronto men to operate claims in Gold Lake district of northeastern Manitoba. Section has been known for several years, but recent discoveries are several miles from Rice Lake where first properties were opened up. Development work in that section was unsatisfactory, but new property has all indications of making good. It is in the hands of responsible people and will get a fair chance.

CENTRAL AMERICA

Honduras

NEW YORK & HONDURAS ROSARIO (San Juancito)—The directors and officers of the New York & Honduras Rosario Mining Co. have sent out splendidly engraved announcements, to stockholders and friends, of the Thirty-fifth Anniversary of the company's corporate existence and uninterrupted operation, dating from Nov. 17, 1880.

The Market Report

Metal Markets

NEW YORK—NOV. 24

The outstanding feature of the metal markets last week was the extraordinary strength of copper, which advanced further on large business. Spelter also was stronger. Lead was stationary, but firmer in tone. Tin advanced.

Copper, Tin, Lead and Zinc

Copper—On Thursday, Nov. 18, the market opened at 19c., r.t., on which basis it had become firmly established on the previous day. A large business was done, and before the end of the day 19¼c., r.t., was realized on million-pound lots. The story of the following days is about the same up to Nov. 23, when the market rested at 19¾c., r.t. Some sellers were asking 20c., but, reports to the contrary notwithstanding, this price had not been realized on any important business up to the close of our week of record, and at the close copper was still available in large quantity at 19¾c., r.t.

The advance was orderly throughout the week. Whenever any producer sold all he wanted to at a certain price he raised his asking price ¼c. per lb., while others kept on selling at the previous price until they too had disposed of all they wanted to at that price.

The volume of business done during the week was large, possibly as large as in the previous week. The major portion of it appears to have been done, however, in the early part of the week at prices from 19@19½c., r.t. Business with domestic manufacturers predominated. There was a good demand from wire drawers and an improved demand from the rolling mills. The bulk of the sales was for copper to be delivered the first quarter of 1916. There were some contracts running ahead to May and June. The larger producers report themselves excellently sold up. In some cases the entire expected output for the next four months has been contracted.

Copper Sheets, base price is 24¼c. per lb. for hot rolled and 25¾c. for cold rolled, with usual extras. Copper wire is 20@20¼c. per lb., carload lots at mill.

Copper Exports for the week ended Nov. 6 are reported by the Department of Commerce at 5,820,478 lb., of which 2,241,175 lb. went to Sweden, 1,652,869 to France, 706,337 to Italy, and 508,744 to England. Imports for the week were 953,521 lb. metal and 969,248 lb. in ore and matte; 1,922,769 lb. in all. The chief imports were from Peru, Japan and Canada.

Visible Stocks of Copper in Europe on Nov. 15 were: Great Britain, 15,473; France, 1,645; afloat from Chile, 1,050; afloat from Australia, 3,400; total, 21,568 long tons, a decrease of 3,317 tons from the Oct. 31 report.

Tin—This market experienced a natural reaction from the sharp advance in the previous week. It might have gone further, keeping step with the decline in London, were it not that the supplies of spot tin here are so tightly held. The volume of business during the week was rather light.

Lead—A good business was done, but conditions were quieter than in the previous week. The St. Louis market was a little stronger, especially owing to the sharp demand for chemically hard lead.

Spelter—The conditions in this market are chronically mixed. The change from week to week in the confusion is purely relative, more or less. Last week was one of those in which the confusion was more. Spelter for prompt and early delivery sold up to 18½c. Contracts for December-January-February shipments were taken at 16½@16¾c. Some considerable business for the second quarter of 1916 was done at 14½c. The total volume of business was not very large. The major portion of what was done in some important quarters was for export. Sales to Great Britain were but trifling, the producers reporting that they could not realize the published prices. On the other hand, France was a free buyer. In this country the galvanizers did some buying, out the larger part of the business was with the brass makers. Brass special spelter for delivery during the first quarter of 1916 sold at 18@20c. per lb.

The continued strength of the spelter market causes a good deal of surprise. The explanation offered in a well-informed quarter is the following: The present American consumption for brass is about 240,000 tons, for galvanizing, 100,000 tons, for sheet zinc and miscellaneous purposes, 60,000 tons; the exportation is about 120,000 tons. This gives the total requirement at the rate of 520,000 tons. The present rate of production is probably about that, or only a little in excess of it. The accumulation of unsold stocks so far has been confined to the superior grades of spelter, of which there is undoubtedly an accumulation. The output of the new smelting works has not yet attained large proportions, and probably will not until after the end of this year.

Zinc Sheets base price was advanced ½c. on Nov. 18, making it $19.50 per 100 lb. Nov. 22 there was a further advance and the base price today is $22 per 100 lb., f.o.b. Peru, Ill., less 8% discount. Demand is good.

DAILY PRICES OF METALS IN NEW YORK

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St. Louis is given as the basing point. St. Louis and New York are normally quoted 0.17c. apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars. Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash. The difference between the price delivered and the New York cash equivalent is at present about 0.20c. on domestic business. The price of electrolytic cathodes is 0.05 to 0.10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands. Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St. Louis being the basing market. We quote the New York price at 17c. per 100 lb. above the St. Louis price.

Silver quotations are in cents per troy ounce of fine silver.

Some current freight rates on metals per 100 lb. are: St. Louis-New York 17c.; St. Louis-Chicago, 6.3c.; St. Louis-Pittsburgh, 13.1c.

20	24⅞	.....	.....	.....	.....	.....	.....	.....	.....	.....	.....
22	25⅛	82⅛	82⅛	96½	20.22	172	170	27⅛	5.74	100	20.92
23	25⅛	81⅞	82⅛	98	20.55	168½	167¼	27⅛	5.83	100	20.96
24	26⅛	80½	80⅞	98½	20.66	166½	165¼	27	5.67	100	20.96

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 3 per cent. discount. For convenience in comparison of London prices, in pounds sterling per 2240 lb., with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4.80. £15 = 3.21c.; £20 = 4.29c.; £30 = 6.43c.; £40 = 8.57c.; £60 = 12.85c. Variations, £1 = 0.21½c.

Other Metals

NEW YORK—Nov. 24

Aluminum—Conditions in the market are not changed, and metal for early delivery commands a high price. Futures are lower. Current quotations are 57@59c. per lb. for No. 1 ingots, New York. As high as 60c. is reported paid for one lot.

Antimony—Supplies are scarce and futures uncertain, owing to the difficulty about arranging for shipments of Chinese, and delays in transit. Business has been on a small scale this week, and prices have advanced again, ordinary brands bringing 39@41c. per lb. Cookson's is quoted at 47c. per lb., but is almost wholly nominal, as very little is to be had.

Antimony ore is also scarce. Only a small quantity is offered at about $2.40 per unit.

Quicksilver—Prices continue high in view of a good demand, with only moderate stocks. New York quotations are $105 per flask of 75 lb. for large quantities and up to $110 for smaller orders. San Francisco reports by telegraph an active market, with sales up to $105 per flask. London price remains £16 10s. per flask, with no discount from second hands.

Nickel—There is no change to be noted. Ordinary forms are still nominally 45@50c. per lb., according to size and terms of order. Electrolytic nickel is 3c. higher. The exports have been about the same as last year, a decrease in shipments to Germany being made up by an increase in those to Great Britain.

Minor Metals—Current quotations for **Bismuth** are $3 per lb., New York.—**Cadmium** is quoted at 7s. per lb. in London; $1.75@1.90 per lb., New York.—**Chromium metal,** 75c. per lb., New York.—**Cobalt metal,** 97% pure, is sold at $2 per lb.—**Magnesium,** pure, has gone to a high price, $6 per lb. being asked.—**Selenium** varies from $2.50@3 per lb., New York, for large lots; $4.50@5 for retail quantities.

Gold, Silver and Platinum

NEW YORK—Nov. 24

Gold production in the Transvaal in October was 797,631 oz., being 20,881 oz. more than in September, and 63,885 oz. more than October, 1914. For the 10 months ended Oct. 31 the production was 6,967,166 oz. in 1914, and 7,531,547 oz.—or $155,667,076—in 1915; an increase of 564,381 oz. this year.

Actual arrivals of gold from Europe at New York were $15,750,000 for the week.

Exports of gold from Australia in the months of July and August were £3,468,676, which compares with £444,271 in the corresponding months of 1914. The large increase this year was mainly in shipments to San Francisco from Sydney.

Platinum—Prices are still rising, and are fast becoming altogether nominal, each transaction being a separate negotiation. Sales have been made from $64 up to $70 per oz. for refined platinum. Some dealers decline to quote.

Silver—The silver market has suddenly advanced, owing to combined buying on Mint orders and on India and continental account. It closed at 26¼d. in London and 54½c. in New York.

Shipments of silver from London to the East Jan. 1 to Oct. 27, as reported by Messrs. Pixley & Abell:

	1914	1915	Changes
India	£4,679,500	£3,394,000	D £1,285,500
China	42,000	6,250	D 35,750
Total	£4,721,500	£3,400,250	D. £1,321,250

China has been taking very little silver this year, having sold as much or more as has been received in the country.

EXPORTS AND IMPORTS

Imports and Exports of the Minor Metals in the United States eight months ended Aug. 31, in pounds except platinum which is in ounces:

	Imports 1914	Imports 1915	Exports 1914	Exports 1915
Nickel	27,080,939	34,159,151	19,203,732	20,001,725
Antimony	10,031,198	12,942,755	3,673	950,867
Aluminum	10,559,359	6,332,873	18,939	40,102
Quicksilver			24,441	150,042
Platinum, oz	51,821	27,002	143	9

Exports include reëxports of foreign material. Exports of aluminum manufacturers—not included above—were valued at $642,133 in 1914, and $2,678,770 in 1915. Nickel and antimony include contents of ore, matte and regulus.

The tin smelting plant of the American Smelting and Refining Co. at Perth Amboy, N. J., will start up about Jan. 1, it is expected. The initial capacity will be 750 tons monthly.

Exports and Imports of Secondary Metallic Products in the United States, eight months ended Aug. 31, in pounds:

	Exports 1914	Exports 1915	Imports 1914	Imports 1913
Copper sulphate	6,925,087	10,038,396		
White lead	12,201,138	15,926,023		
Zinc oxide	20,069,717	28,473,070		
Zinc dust	47,557	293,358	3,025,911	903,738
Zinc dross	648,631	7,387,208		

The exports of zinc dust reported were all reëxports of foreign material.

Zinc and Lead Ore Markets

PLATTEVILLE, WIS.—Nov. 20

The base price paid this week for zinc ore was $100@108 for 60% grades. The base price paid for 80% lead ore was $64 per ton.

SHIPMENTS, WEEK ENDED, NOV. 20

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	4,796,000	310,000	$31,300
Year	183,567,750	6,338,640	25,693,990

Shipped during week to separating plants, 5,044,000 lb. zinc ore.

JOPLIN, MO.—Nov. 20

Blende, high price $118; base per ton 60% zinc, premium ore, $115; medium, $114@105; lower grades down to $100; calamine, base per ton 40% zinc, $80@70; average selling price, all grades of zinc, $101.67 per ton. Lead, high settling price, $65.75, base per ton 80% metal content, $64@70; average selling price, all grades of lead, $62.50 per ton.

SHIPMENTS WEEK ENDED NOV. 20

	Blende	Calamine	Lead	Values
Totals this week	13,307,750	2,238,480	2,360,100	$864,100
Totals this year	519,789,440	38,661,560	81,149,870	$23,510,480

Blende value, the week, $715,500; 47 weeks, $20,407,500.

Calamine value, the week, $74,850; 47 weeks, $955,080.

Lead value, the week, $73,750; 47 weeks, $2,147,900.

Sellers held out until noon Friday for $125 for premium ore, but buyers would not offer in excess of $115 and transactions were made at this figure. The advance for blende was $5; calamine advanced $10 and lead $6 per ton. The bulk of reserve ore has been held at Granby, 1,200 tons of the 4,000 tons being shipped this week, with the sale of another 1,000 tons for next week's shipment. Practically all smelting companies closed the week with large purchases for next week's delivery.

Iron Trade Review

NEW YORK—Nov. 24

The iron and steel markets are now fairly on the boom. The mills are everywhere full of orders and in some cases premiums are being asked for early deliveries.

The rush is not all for export trade, as domestic orders are piling up steadily and price advances have not checked the demand. The latest branch of the trade to show rising activity is structural steel. Orders for new construction are being placed rapidly. The demand for plates and shapes for shipbuilding have added to the rush, while new cars are being rather freely contracted for.

Exports from Baltimore for the week included 1,824,700 lb. tinplates to Glasgow.

The pig-iron market is strong and advances of 50c. per ton are recorded. Foundry-iron demand has shown a notable increase, and in some cases early deliveries are sought. Furnaces are going into blast where it is possible, and it looks as if November and December would improve upon the record production of October.

PITTSBURGH—Nov. 23

Buyers of steel seem to be exerting as much pressure as ever to secure the acceptance of orders by steel mills. Recent advances in steel prices were made with the full expectation that demand would be curtailed thereby, the mills feeling amply strong to stand such a decrease, and in the circumstance of demand being as heavy as ever further price advances are now predicted. Last Thursday noon the Carnegie Steel Co. advanced its price on bars, plates and shapes from 1.60c. to 1.70c., and the advanced price was at once adopted by other mills, making a total advance in these products from 1.40c. to 1.70c., or $6 a ton, in five weeks. Galvanized sheets are up $5 a ton, to a range of 4.50 to 4.75c., black sheets being stronger at 2.40 to 2.50 cents.

Steel interests are canvassing all possibilities of increasing production, but erection work promises to be slow and new construction is undertaken only where the conditions are particularly favorable. Pig iron and steel making capacity will not increase by more than a very few per cent. in the next twelve months, by additions at various points and the

completion of a few complete plants that have been under way for a long time.

The Pennsylvania R.R. system on Saturday decided not to buy any freight cars, finding prices and deliveries proposed under its inquiries for 9,000 cars unsatisfactory. The plate mills involved profess relief that the business is postponed. Other roads are slower than was expected in placing car orders, but nevertheless at least 15,000 freight cars have been bought thus far this month.

Inquiry for structural material has increased, indicating at least fairly heavy building operations next season. The demand for structural steel to date has been conspicuously light as compared with demand for other steel products.

Prices on Lake Superior ore for the season of 1916 are likely to be announced before the week is out, at an advance of 75c. or $1 a ton over the schedule obtaining in the past season, these prices having been the same as for 1912 and 1914 and the lowest since 1904. In ore circles it is stated that all the ore available can be sold in a few weeks, large reservations having already been made, and that the limit will be fixed by lake transportation facilities, rather than by mining capacity, and at 55,000,000 to 60,000,000 tons for the season, against the previous record of approximately 50,000,000 tons in 1913.

Pig Iron—The Republic Iron & Steel Co. has bought 25,000 tons of bessemer pig iron from a Shenango Valley furnace interest at $17 at furnace for shipment over the first three months of next year, the market thus being established at an advance of 50c. A few small lots had already been sold at the figure. Offerings of basic iron are limited and an early advance is predicted, with possibilities of continued and sharp advances as there are only two idle merchant furnaces now in the general district. Foundry iron is stiffening sharply, even in the face of a rather light demand, and quotations are 50c. higher than a week ago, with some furnaces quoting above the general range. We quote: Bessemer, $17; basic, $16@16.25; foundry and malleable, $16@16.50; forge, $15.50@16, f.o.b. Valley furnaces, 95c. higher delivered Pittsburgh.

Ferromanganese—Supplies from England are coming in more freely. The English price on contract is steady at $100, Baltimore, while domestic producers may possibly occasionally shade their former quotation of $110 on contract.

Steel—Quotations are difficult to obtain on bessemer steel, while openhearth is scarcely quoted at all, mills being completely sold up for near-by positions and being unwilling to quote for late deliveries. The market is regarded as quotable approximately at the following advanced figures, though the prices are largely nominal: Bessemer billets, $27; bessemer sheet bars, $28; openhearth billets, $28@29; openhearth sheet bars, $28.50@29, f.o.b. maker's mill, Pittsburgh or Youngstown. Rods are about $35 and forging billets about $48 at mill.

FERROALLOYS

Ferrosilicon, 50%, is quoted $83@85, Pittsburgh, according to quantity. Bessemer ferrosilicon is quoted from $33 for 16% down to $23 for 10%, all at furnace.—**Ferrotitanium** is 8@12½c. per lb., according to size of order.—**Ferrotungsten** continues to command high and irregular prices. A sale of **Tungsten** metal, 98% pure was made this week at $7 per lb. for a lot of 500 lb.; and higher prices are expected.

IRON ORE

The leading ore shippers on the Lakes came into the market last week and chartered all the available tonnage to carry ore next season. These charters were made at an advance of 10c. over those for the season just ending, making the rate net to the ship for 1916 delivery 50c. from the head of the lakes, 45c. from Marquette and 35c. from Escanaba.

The anticipated need of a larger quantity of iron ore than had been expected, combined with delays in November ore shipments caused by bad weather, have made heavy shipments of ore imperative in the short time remaining of the season. About all the wild boats available have been chartered, and it is understood that $1 a ton has been paid for ore from Duluth to a Lake Erie port.

Shipments of iron ore from deposits near Waukon, Iowa, are being made to South Chicago, where the ore will be used in the Iroquois Iron Co.'s stacks as an experiment. Possible shortage of Lake Superior ore has led the company to seek a reserve supply from Iowa and tests will be made at once to determine the practicability of its use in ordinary practice. Several thousand tons have been contracted for.

Imports and Exports of Iron Ore in the United States nine months ended Sept. 30, in long tons:

	1914	1915	Changes
Imports	1,094,972	971,098	D. 123,874
Exports	536,115	508,557	D. 27,558

Leading imports this year were 610,698 tons from Cuba and 151,619 tons from Sweden.

British Iron Ore Imports 10 months ended Oct. 31 were 986,518 tons in 1914, and 5,108,770 in 1915; increase, 122,252 tons.

OTHER ORES

Manganese Ore—In Great Britain, according to the London "Mining Journal," October imports were above the average, amounting to 60,931 tons, but owing to the fact that freights entirely govern business shipments are necessarily irregular. Prices remain nominal, but business has been done this week at from 1s. 8d. to 1s. 9d. The situation in India is one of sharp competition between sellers, the f.o.b. rates ruling there being from 6 to 6½d., with occasional shading. The conditions of war are tending to reduce output, and stocks are diminishing. The Bombay figures on Oct. 22 last were 85,649 tons.

Imports of manganese ore in the United States nine months ended Sept. 30 were 215,274 tons in 1914, and 173,992 tons in 1915; a decrease of 41,282 tons this year.

Imports of manganese ore in Great Britain 10 months ended Oct. 31 were 444,975 tons in 1914, and 270,745 tons in 1915; decrease, 174,230 tons.

COKE

Production in the Connellsville region for the week is reported by the "Courier" at 427,381 short tons coke; shipments 430,503 tons. Shipments of Greensburg and Upper Connellsville districts were 42,815 tons.

Connellsville—The market for prompt furnace coke is easier, there being offerings down to $2.15, while $2.10 has been done on one or two odd lots. Corrigan, McKinney & Co. are understood to have closed for their remaining requirements for next year, leaving very little uncovered contract business. We quote: Prompt furnace, $2.15@2.25; contract, first half, $2.35@2.50; year 1916, $2.25@2.35; prompt and contract foundry, $2.90@3.25, per net ton at ovens.

Exports and Imports of Fuel in the United States nine months ended Sept. 30, in long tons:

	Exports		Imports	
	1914	1915	1914	1915
Anthracite	3,062,057	2,594,754	18,257	2,524
Bituminous	10,902,780	12,421,960	980,284	1,077,799
Coke	485,171	573,084	83,980	36,602
Bunker coal	5,711,948	5,678,815		
Total	20,161,956	21,268,613	1,082,521	1,116,925

The bunker coal or coal furnished to steamships in foreign trade is practically all bituminous. The principal trade, both exports and imports, is with Canada.

Chemicals

NEW YORK—Nov. 24

The General Chemical Co. has declared an extra dividend of 15% on its common stock, payable in new stock. At the same time it is paying its employees a bonus of 10% on their yearly salaries.

Arsenic—Business is quiet, without change. Current quotations are $3.75@4 per 100 lb. for both spot and future deliveries.

Copper Sulphate—Business is steady and sales about as usual. Prices have been advanced and the current quotation is $8 per 100 lb. for carload lots and $8.25 per 100 lb. for smaller parcels.

Nitrate of Soda—Business is fair and prices are a little stronger. High ocean freights are keeping up the quotation. The current figure is $2.90@2.95 per 100 lb. for spot and December; $2.85 for later deliveries.

Pyrites—Imports at Baltimore for the week included 5,983 tons pyrites from Huelva, Spain.

Sulphuric Acid—60° Bé. acid is selling at $60 per ton, f.o.b. works.

Imports and Exports of Fertilizing Chemicals in the United States eight months ended Aug. 31, in long tons:

	Imports		Exports	
	1914	1915	1914	1915
Kainit	317,265	6,646		
Manure salts	150,973	13,647		
Other potash salts	182,091	67,427	2,746	960
Nitrate of soda	371,952	555,846	6,114	14,779
Sulphate of ammonia	51,483	25,745		1,294
Phosphates			899,100	157,806

Exports include reëxports of foreign material. Some phosphates are imported, but are not given separately in the returns.

PETROLEUM

Shipments of Mexican oil to the United States in October from Tampico were 986,616 bbl.; from Tuxpam, 681,968; total, 1,668,584 bbl. This does not include shipments to Europe

Engineering and Mining Journal

VOLUME 100 DECEMBER 4, 1915 NUMBER 23

Magnetic Separation in Sardinia

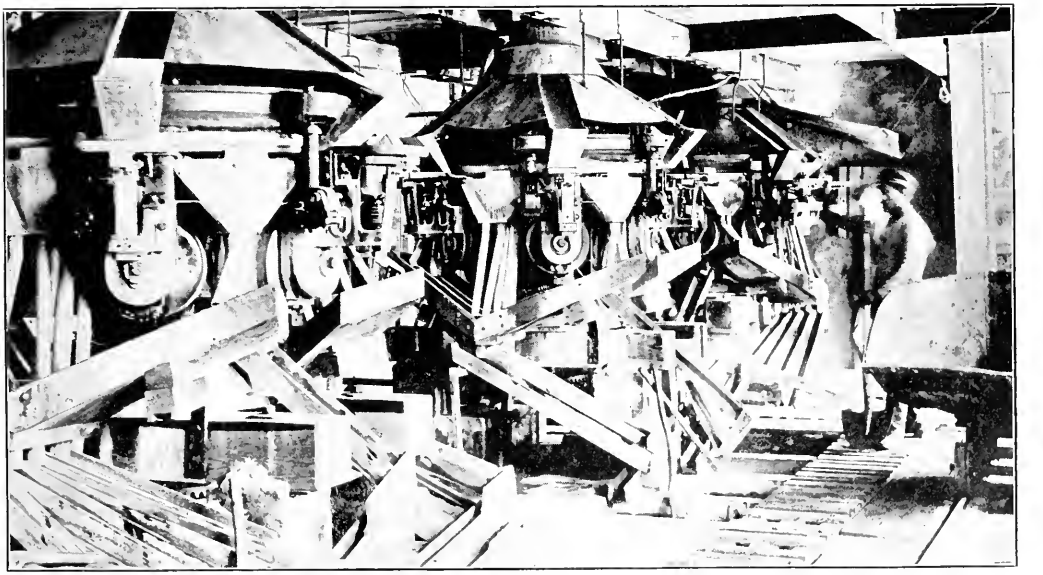
By Charles W. Wright*

SYNOPSIS—In order to improve the recovery at the Gennamari-Ingurtosu mine, Ullrich electromagnetic separators were installed. Results were immediately improved and have continued satisfactory. Description of the process and its cost are given.

The production of a high-grade blende concentrate from ores containing much siderite or pyrite cannot be accomplished satisfactorily by ordinary methods of milling. At most ore-dressing plants where such material is treated, a low-grade product or rich middling containing the blende and heavy gangue minerals is made in the jigs and on the tables. This product is first roasted or calcined so as to make the iron-bearing minerals more magnetic, and it is then separated by a magnetic separator. Such was the process employed until recently in the treatment of the blende-siderite ores at the Gennamari-Ingurtosu mine. The treatment costs, however, were high as well as the metal losses.

To improve these results a series of tests was carried out by the Elmore and Minerals Separation flotation processes, but only fair results were obtained, while the treatment costs were high. Tests were then made with the wet magnetic separators of the Electro-Magnetische Gesellschaft and with the Ullrich separators built by the Fried. Krupp Grusonwerk. The latter machines gave the best results and were therefore installed at our mill. They have now been in operation for over a year, and fairly accurate results as to their efficiency and costs have been obtained.

The occurrence of the blende-siderite ore at the Gennamari-Ingurtosu mine is in a lode that traverses a schistose country rock. This lode has been developed for 3 km. in length and averages from 3 to 15 m. in width. The blende ore is free from other sulphide minerals, and besides the siderite the gangue contains quartz, calcite and some barite, as well as a large amount of the altered schist. Portions of the lode contain well-defined veins, while other parts consist of a schist breccia, the ore forming the matrix. It is also noteworthy that the siderite occurs in greater quantities in certain parts of the lode and that



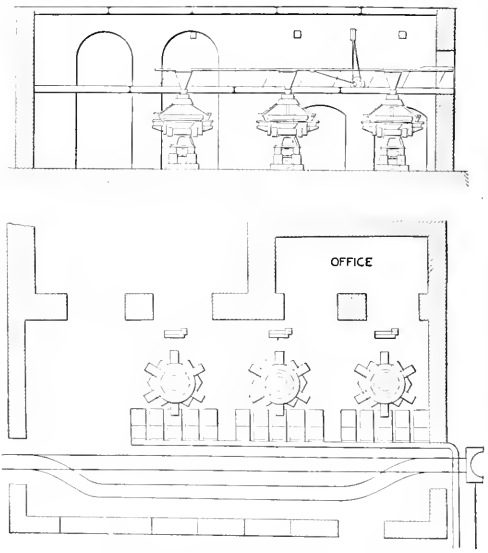
A ROW OF MAGNETIC SEPARATORS IN A SARDINIAN CONCENTRATOR

*Mining engineer, Ingurtosu, Sardinia, Italy.

when possible the ore from these parts is mined and treated separately.

The ore from the mine averages from 10 to 15% zinc. The richer ore is first treated on the *piazzale* by hand sorting and hand jigging to recover the coarse blende, and it is then sent to the mill for further treatment. The lower-grade ore goes direct to the mill. Here it is first reduced to 7 mm. and under, and then screened and 7 sizes made, 6 of which are treated in small four-compartment jigs, and that under 1 mm. size is treated on tables. The jigs produce a blende product, a rich middling of blende and siderite, which is sent to the magnetic separators, and a poor middling which is recrushed and retreated. Similar products are obtained from the tables. All of the rich middlings and in some instances the products containing an excess of siderite are sent to the magnetic-separator plant. The average tenor of the ore subjected to magnetic treatment is from 25 to 35% Zn and from 30 to 40% iron.

The former plant, used until last year for the separation of siderite from blende, consisted of an Oxland



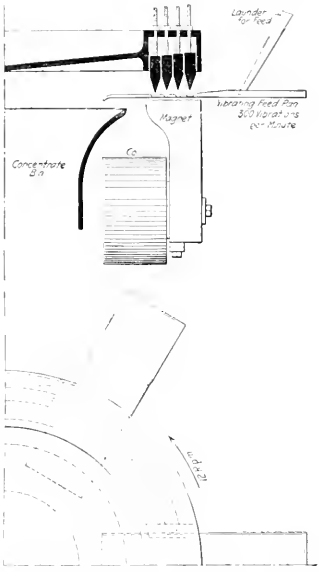
THE MAGNETIC SEPARATING PLANT

revolving calcining furnace and two dry magnetic separators of the Primosigh type. The capacity of this plant was about 1¼ tons per hr. The ore was first calcined in the furnace so as to reduce the siderite superficially to Fe_3O_4, thus making it more magnetic. The furnace was 10 m. long and had a diameter of 0.65 m. inside the fire-brick lining. It revolved at the rate of one revolution in 2½ min. and had a capacity of 1½ tons per hr. The ore before roasting was mixed with 100 kg. of fine coal per ton. The total cost of calcining was 5 lire per ton. The Primosigh separators were in drum form, with electromagnets inside. Passing around this drum and over pulleys at the side were four wide belts. As the ore traveled along a shaking trough under, and at right angles to these belts, the siderite was drawn up on them and carried over the side of the shaking trough, while the blende continued to the end and discharged into a car. To operate the Primosigh separators, 5 hp. was required, and the cost of this separation was 2 lire per ton. The concentrates from the separators contained 50% zinc and 10% iron, and the tailings carried 6% in zinc and 45% iron, the zinc recovery being 93%.

The Reformed Electromagnetic Plant

The new magnetic separation plant consists of a series of three Ullrich magnetic separators arranged in tandem, shown in the illustration. The siderite-blende ore is fed by a bucket elevator to a Ferraris shaking screen, which separates the ore into 3 sizes—0-2, 2-4 and 4-7 mm. Each size is fed to one of the separators along with about 4,000 liters of water per ton of ore.

The Ullrich separators consist of a series of six electromagnets arranged in sextants of a circle. A half-section of the machine is shown in the drawing. Above these magnets are four iron rings which revolve, passing from the positive magnetic field of the first pole to the negative field of the second pole and then to the third pole, which



SYSTEM OF MAGNETIC CONCENTRATION

is positive, and so on, completing the circle in about 5 sec. Between the six electro-magnets and these rings, and traveling at right angles to the rings, are six brass shaking pans, on to which the ore is fed from a central distributor. As the ore passes into the magnetic field, the siderite is drawn up from the pan by the iron rings and is carried off the side of the shaking pan into a trough divided into two compartments. Some of the blende is dragged off of the pan and drops into the first compartment along with some siderite, and this constitutes the middling product, which is retreated. The siderite free from blende is carried forward on the ring to the second compartment, where it is washed from the rings by small jets of water. The blende free from siderite is discharged off the end of the shaking pans into a central launder.

To operate an Ullrich separator, about 1½ hp. is required for the mechanism and a current of 10 amp. at 125

volts is required for the magnets. The entire plant is operated by a 20-hp. motor. The plant runs 10 hr. per day and treats from 2½ to 3 tons per hr.

The ore fed to these separators averages about 34% zinc and 38% iron, the concentrates contain 53% zinc and 5% iron, and the tailings carry 2½% zinc and 48% iron. The zinc recovery by this treatment is 96%, while 90% of the siderite is eliminated from the concentrates.

COST OF PLANT OPERATION

	Lire per Day
Power, 20 hp. × 10 hr. × 0.07 lire	14
Labor, 4 men at 3 lire	12
Repairs, per shift	6
Supervision, per shift	2
Amortization, 70,000 lire in 10 years	28
Total cost per day	62
Cost per ton treated (25 tons per day)	2.48

The total cost of the plant was 70,000 lire. The cost of operating is given in the accompanying table.

Injury to Mine Timbermen

By A. L. H. Street*

The Michigan Supreme Court was lately called upon to determine the liability of a mining company for injury to a timberman, caused by fall of rock, where he entered the place without looking and in advance of the usual announcement of the timber boss that it was safe to enter. (Vrelenich vs. Calumet & Hecla Mining Co., 154 Northwestern Reporter, 39.) The court holds that there can be no recovery under such circumstances; that the rule of law that requires an employer to use reasonable care to provide a safe place of work for his employees does not extend to the occupation of timbermen, for the very nature of their work is to make places safe for the miners to follow them. The employer's full duty to timbermen is discharged, the court declares, when reasonable rules are promulgated, the workmen are properly instructed, and when suitable tools and materials are furnished for the work, with competent men to perform it.

The fellow-servant rule was applied in a similar case by the same court (Kangas vs. Cleveland-Cliffs Iron Co., 154 Northwestern Reporter, 41). Plaintiff was a timberman working on a night shift and was injured through fall of a rock through a hole leading up into an old stope, and suit was brought on the theory of negligence of the day crew in not blocking up the hole. But recovery was denied on the ground that the members of the two crews were fellow-servants. The court expressly decides that it is not necessary, in order to constitute men "fellow-servants" within the rule in force in Michigan, exonerating an employer from liability for their negligence toward one another, that they be engaged in the common work at the same time. It is sufficient that they be engaged in the same work designed to effect the same general purpose.

Recent Scarcity of Monazite from Brazil, according to a consular report from Madras, has directed attention to the possibilities for commercial development of the large deposits of monazite sand in Travancore, South India. The production of monazite in British India in 1913 was valued at over $200,000. Most of the output was exported in a raw state. A European firm recently purchased land in South Travancore for the express object, it is said, of carrying on an export trade in monazite. It is now announced that under a recent order of the British Government the export of monazite sand from British India except to the United Kingdom is prohibited.

*Attorney, Security Bldg., Minneapolis, Minn.

Conservation of Mineral Resources*

For purposes of illustration and comparison the losses caused by the waste that conservationists hope to lessen or to eliminate are usually expressed in tons or in terms of monetary value, but as our individual ideas of the value of money vary widely, I should prefer to discuss these losses in terms of a labor-unit value. The statement that in certain industries a loss of $1,000,000 per day is caused by waste conveys vaguely the idea of great loss, but if we express this by stating that a loss of 500,000 days of labor is daily caused by waste, this statement conveys the same idea to all, namely, that the labor of 500,000 employees is wasted every day—a concrete statement of fact that gives a more definite conception of what waste really means, for going one step farther, we see that if this waste could be avoided we would immediately have available the labor of an army of 500,000 men, which could profitably be employed in other productive industries.

I have introduced this homely example because it directs attention to the value of labor as a national asset and as the real basis of our prosperity and the foundation of all wealth. The engineer should remember that the conservation of labor is more important than the conservation of coal or other resources which the Creator has furnished us in most abundant supply, for labor that is unnecessarily expended is an absolute loss and never can be regained.

Conservation of Labor the Great Aim

Conservation of labor is more important than any other economic issue and should be adopted as a governing principle of national policy. The object of the engineering sciences is to produce a given product or to accomplish the greatest quantity of work of any kind, with the least possible expenditure of labor. This is sometimes called engineering efficiency, but is more broadly described by the term conservation of labor.

I may perhaps make this meaning clear by a concrete example illustrating the application of the principle of conservation of labor to mining. If we assume that one ton of iron ore can be mined and prepared for shipment to the blast furnace from average mines at an average cost of one day's labor, it would be an economic waste to attempt to mine iron ore from deposits that require two or three days' labor per ton of ore produced, because by employing one day's labor at a mine of the first-mentioned class the same quantity of ore could be produced and two days' labor would be released for employment in other useful work; and it would be a similar economic waste to attempt to recover ore from the tailings or waste dumps of a mine of the first class, if the recovery of each ton of ore from this material required the expenditure of two or three days' labor.

The same principle of the conservation of labor may be applied to all mining and metallurgical industries, the rule being that labor is unwisely expended when the labor cost of producing any product exceeds the average labor cost at which the product can normally be produced.

*Excerpts from an address delivered by H. M. Chance at the dedication of the Mines Building at Pennsylvania State College, State College, Penn., Nov. 5, 1915.

I would now like to say a few words in defense of the coal-mine managers and engineers whom conservationists of the extreme type charge with wholesale waste in the mining of coal. The fact that many graduates of this School of Mines are now employed in coal mines justifies discussion of this subject in some detail.

Most of our bituminous coal is mined from coal beds that are nearly or quite horizontal, and it will easily be understood, even by those who never have visited a coal mine, that as the coal is removed some method must be provided for supporting the roof of the workings; that is, for sustaining the great weight of rocks that lie upon the coal and extend from the coal bed up to the surface of the ground. By what is known as the longwall system of mining some coal can be worked without supporting the roof, which is allowed to settle down and fill the space made by the removal of the coal, but in most mining districts the use of this system is not feasible and the roof must be supported to a greater or lesser extent as the coal is removed. Timber, structural steel and concrete or rubble masonry have been used for this purpose, but these materials are costly and therefore are used sparingly. At present prices the cost of timber, rubble masonry and concrete per cubic yard is respectively about $12, $4 and $6, while loose material such as sand or gravel, or broken stone (brought into the mine and used for the purpose of supporting the roof) will vary in cost in different localities, but will range usually from 75c. to $1.50 per cu.yd., plus the cost of timber or masonry necessary to confine and hold these loose materials in place.

To Waste Coal Is Sometimes To Save Labor

As the value of coal in the ground as measured by royalty rates is rarely greater than 10 or 15c. per ton, in using concrete or rubble masonry, or even loose materials to support the roof, the engineer must so design these supports that each cubic yard of material so used will permit of the mining of from 15 to 40 tons of coal, but this is rarely possible, as in most cases a cubic yard of masonry or concrete would be necessary for each 10 or 15 tons so mined. If this method were adopted the cost of the coal would be increased about 30c. per ton.

As it is obviously foolish and wasteful to use high-priced materials when other cheaper materials are available, the mining engineer has preferred to substitute in place of masonry for supporting the roof, certain portions of the coal bed itself, which by the plans for working the coal, are not to be mined but are to be left as pillars to support the roof, thus substituting in place of concrete or rubble masonry costing $4 or $5 per cu.yd., coal that has a nominal value (but no labor value because no labor has been expended upon it) of but 10 or 15c. per cu.yd. The coal left as pillars to support the roof is thus utilized and performs a necessary and useful function, yet the principal part (perhaps two-thirds) of the 200,000,000 tons our friends the conservationists claim is willfully and avoidably wasted every year is this coal that is left in pillars to support the roof. I think we can safely claim that this is not waste, but on the contrary is engineering efficiency of the highest type, in that it utilizes the cheapest and least valuable material available to support the roof and saves the whole labor cost of building supports of other materials.

Investigation as to what becomes of that part of the 200,000,000 tons claimed as wasted, that is not utilized as pillars to support the roof, will disclose the fact that a large portion is coal that is left in mine workings that are abandoned because the roof is unsafe and because a continuance of operation would result in injuries or loss of life. Coal left in the mines in order to conserve human lives cannot be classed as avoidable waste. A small part of the 200,000,000 tons is lost because it is intimately mixed with refuse and because the labor cost of recovering it and separating it from the refuse would be greater than its value.

Relative Values of Our National Assets

If we are to realize the full benefits of conservation, it becomes necessary to distinguish clearly between the relative values of the assets sought to be conserved, otherwise waste of the more valuable assets may result from the efforts to conserve those of less value. From an industrial and economic point of view our national assets may be grouped as to relative values in the following order:

1. The life of the workman.
2. Labor.
3. Capital (the accumulated products of labor).
4. Supplies needed for current consumption.
5. National resources—timber, minerals, water power, fish, animals, fertility of the soil, etc.

The acceptance of the principle of conservation as applied to human lives is shown by the extension of "safety-first" methods to nearly all industries. "Safety first" has always been the motto of the mining engineer. Most mine accidents are caused by unusual or unforeseen conditions, or by ignorant or careless workmen, or by lack of knowledge of what constitutes a dangerous condition. Mine accidents have rarely, if ever, been traced to a disregard of the safety-first principle by engineers.

Next in importance to the conservation of life, engineers have always placed the conservation of labor. In conserving labor by so directing its application as to secure the best results at the lowest labor cost, the engineer protects the capital invested in industrial enterprises and secures satisfactory profits as compensation for its use.

Capital is increased by conservation of the supplies carried in stock to meet the requirements for current consumption, and accumulated wealth grows principally from the surplus thus saved.

A proper regard for the conservation of our national resources is imposed upon the engineer by the ethics of his profession, and we can feel sure that this duty will be performed efficiently and conscientiously by the graduates of the Pennsylvania State School of Mines and of other similar institutions.

In preparing this brief discussion of the conservation of mineral resources in its relation to the work of the School of Mines, my object has been to present the subject in a form capable of being understood by the student at the very threshold of his entrance upon the study of engineering. A further object has been to furnish a reply to the exaggerated and misleading statements promulgated by conservationists—a reply which could be understood by those who are not familiar with mining and metallurgical work, and which would show by simple and logical arguments that the engineer should not risk human life, waste the labor of employees, risk the loss of the capital of his employer or waste materials or supplies by attempting to carry out in practice doctrines or theories based upon the teachings of conservationists of the extreme type.

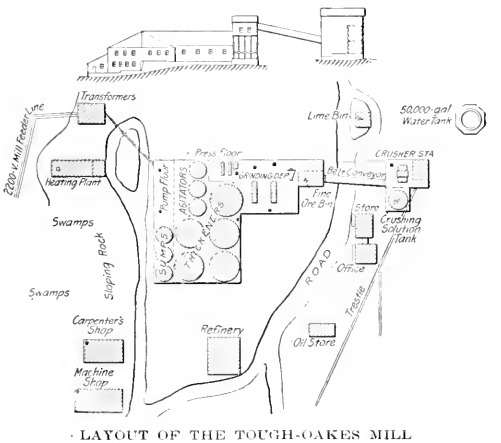
Building the Tough-Oakes Mill—II

By John A. Baker*

SYNOPSIS—Continuing the description and cost of the erection of the Tough-Oakes mill. The heating system, electrical motive-power machinery and equipment, piping and transmission machinery are discussed in detail. Finally, the metallurgical operation of the mill is described.

Since it is necessary to maintain a temperature of about 65°, the problem of economical heating during eight months of the year merits careful consideration. Low-pressure steam, using the gravity-return system, is employed. The boiler is of the inclosed-firebox type, designed for carrying 15 lb. of steam as a maximum. It is rated to supply 8,500 sq.ft. of steam radiation. The water level of the boiler is 5 ft. below the bottom of the lowest radiator in the mill. This factor is important if the radiators are to be kept free from water.

The boiler building has concrete retaining walls and floor. It is 15 ft. wide and 50 ft. long, with 12-ft. wall.



LAYOUT OF THE TOUGH-OAKES MILL

Included in this is a coal bin, 15x10x12 ft., at the eastern end of the building. The boiler setting is a combination of a brick arch and stone side walls lined with one course of brick. The stack is of steel and is 36 in. in diameter and 60 ft. high.

The total area of all radiators installed is 6,000 sq.ft. The total cubic contents of all buildings heated is 338,000 cu.ft. This gives a ratio of 1 sq.ft. of radiator surface to 56 cu.ft. of volume. This is over 10% less than the amount recommended by radiator manufacturers, but has been found ample, even in the severest weather.

The average coal consumption per day is about 2.5 tons, costing $10 per ton. With attendance, this amounts to $30 per day, or a total of $7,200 for eight months. In round figures, then, the heating of every 1,000 cu.ft. of building volume costs $50 per annum.

*Formerly Construction Engineer for Tough-Oakes Gold Mines, Ltd

The total cost of installation, excluding boiler plant, is $13 per 1,000 cu.ft. Including boiler plant, the cost is $21 per 1,000 cu.ft. The detailed cost of the boiler house is shown in the accompanying table.

TABLE 6. COST OF BOILER HOUSE

	Labor	Material	Total	Labor in Cost	Supervision	Total
Clearing, excavation and foundations..	$222.60	$93.81	$316.41	70%	.....	.....
Building and erection	265.45	358.30	623.75	42%	.....	.....
Boiler setting and equipment	759.09	1313.70	2072.79	36%	.....	.....
Totals	$1247.14	$1765.81	$3012.95	41%	$198.95	$3211.90

The weight of the boiler, stack and trimmings complete was 14,000 lb. and the laid-down cost at the mill site was $1,140. Six thousand red brick at $22 per M and 400 firebrick were used in the setting. The main steam line is 7 in. and the water-return main 5 in. in diameter. The summarized cost of the heating system distributed among the various buildings is shown in Table 7.

TABLE 7. COST OF HEATING SYSTEM

Building	Labor	Material	Total	Labor in Cost	Supervision	Total Cost
Crusher station.	$109.77	$248.48	$358.25	31%	.....	.....
Cyanide plant..	731.45	2800.95	3532.40	20%	.....	.....
Office	14.58	43.44	58.02	25%	.....	.....
Storehouse	6.03	20.00	26.03	23%	.....	.....
Carpenter shop.	25.59	46.03	71.62	35%	.....	.....
Machine shop..	53.98	107.37	161.35	33%	.....	.....
Totals	$941.40	$3266.27	$4207.67	22%	$499.40	$4707.07

Floor radiators costing 19.5c. per sq.ft. are used in the crusher station, office and shops. In the cyanide plant, wall-type radiators costing 22.4c. per sq.ft. are employed on account of the limited floor space. Cost of maintenance is higher for this type than for the floor radiators. This statement may appear to be contradicted by the higher cost of labor in the crusher station. This is not the case, however, since the higher labor charge in this case is due to the extra work on the trench and box carrying the pipes between the two buildings.

Electrical Power Equipment

All power used on the property is supplied by the Charlton & Englehart Power Co. The transmission line is 28 miles long and carries 33,000 volts. The frequency is 60 cycles, and the voltage is stepped down to 2,200 at a central transformer station. From here, the mill feeder line of 000 copper 1,630 ft. long connects with the mill transformer station. All mill motors use 550 volts. There are two sets of outside lightning arresters, pole-mounted. Cedar poles 30 to 35 ft. long and not less than 7 ft. at the top were used, the maximum distance between poles being 120 ft. All pole fittings are galvanized, and poles are securely guyed and dead-ended. As the line crosses a low-lying area covered with muskeg, some difficulty was at first experienced in digging post-holes, owing to the surface water. The muskeg is about 2 ft. deep over a bed of impervious clay. A box, open at both ends, 36 in. square and 30 in. deep, was forced down through the muskeg to the clay. This sealed off the muskeg water and permitted the remainder of the hole to be dug with ease. The cost of the pole line is given in Table 2, and

also in Table 9 of detailed electrical costs. It is at the rate of $3,930 per mile.

At the mill transformer station the voltage is stepped down from 2,200 to 550 volts in a bank of three 150-kv.-a. single-phase Westinghouse transformers. Space is left for a second bank in the same building. A main oil-switch of 450-kv.-a. capacity with indicating wattmeter is placed on the secondary side of the transformers. From the switch the main circuit runs to the busses of the mill switchboard upon which are six plain disconnecting switches controlling the motor circuits. All 550-volt conductor used in the mill is cable and is placed in conduit. The data on the various circuits are shown in Table 8.

A 10-kv.-a. lighting transformer, 2,200 primary to 110 secondary, is connected directly to the high-tension bus bars. A separate meter and switch control the 110-volt side. The lighting mains run along the outside walls of the mill to two Crouse-Hinds distribution panels, one in the central portion of the cyanide plant and the other in the crusher station. From these centers, 12 separate lighting circuits control the group lighting. Tungsten lamps are used throughout. For general illumination in the cyanide plant, 600-watt nitrogen-filled tungsten lamps with ground-glass bulbs are employed. If properly erected, these lamps last 5 or 6 months. No arc lamps are used.

TABLE 8. MOTOR-CIRCUIT DATA

Circuit No.	Length Ft.	Wire Size	Conduit Size	Motors Hp.	R.p.m.	Driven Machinery
1	120	2	1¼	40	580	2 centrifugals, vacuum and triplex pumps.
				20	690	Low-pressure air compressor.
				15	1120	5 thickeners, 3 agitators, 4 diaphragm pumps.
2	125	2	1¼	10	890	Conveyor belt and lime elevators.
				10	890	2 Dorr classifiers and elevators.
3	280	2	1¼	50	580	2 crushers, elevator, trommel and skip hoist.
4	50	4	1¼	40	580	16x60 Hardinge ball mill.
5	20	00	2	100	580	5x20 tube mill.
6	20	00	2	100	580	5x20 tube mill.
Main Feeder	2 Circuits 75	250,000 C.M.	2½	All motors		Total mill load.

Total shipping weight of all motors, transformers, starters, etc., 46,000 lb. Laid-down cost, 18c. per lb.

All motors are of the Westinghouse G.M. mill type. With the exception of the circuits Nos. 3 and 4, all machines are much underloaded. Conductor size permits of 25% overload on each machine on the circuit. All motors 40 hp. and over have panel-type starter and ammeter. Smaller machines have the standard starter. With this starter an asbestos-lined box with knife switch, starting and running fuses is used. The summary of the detailed electrical costs is given in Table 9.

TABLE 9. COST OF ELECTRICAL EQUIPMENT

Building	Labor	Materials	Total	Percentage of Labor	Supervision	Total
Crusher station	$65.60	$856.68	$922.28	7.1	.....	.....
Cyanide plant	559.09	5,789.03	6,348.12	8.7	.....	.....
Transformer station	171.17	3,508.15	3,679.32	4.7	.....	.....
Machine shop	70.02	194.00	264.02	26.9	.....	.....
Power line	420.16	712.00	1,132.16	38.0	.....	.....
Total	$1286.04	$11,059.86	$12,345.90	16.4	$760.45	$13,106.35

The total cost does not include the transformer building.

The number, size and cost of motors and transformers can usually be estimated at an early stage of mill design. In the case of the Tough-Oakes, the total laid-down cost was $8,282. The ratio between this sum and the total of Table 9 gives us 1.6, a useful factor for estimating purposes.

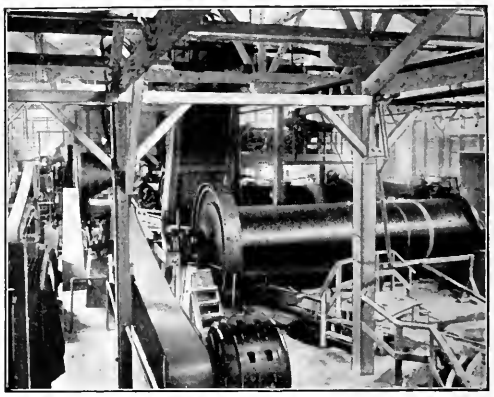
Estimating the amount of pipe that will be used in a mill is not so easy as might appear. While in no sense a standard, the exact bill of piping used in the Tough-Oakes should be of interest and is given here.

DETAILS OF PIPING ON THE PLANT

Size, In.	Amount Ft.	Price per 100 Ft.	Size, In.	Amount Ft.	Price per 100 Ft.
¾	51	3.00	2	1,900	9.90
1	102	3.50	2½	250	16.07
1¼	163	4.00	3	1,173	21.04
1½	880	4.25	3½	473	25.27
1	1,209	4.59	4	3,708	29.94
1¼	240	6.50	5	104	42.25
1½	1,430	7.42	6	150	54.45

These prices are for carload lots f.o.b. Swastika and are the lowest of several competitive bids. The foregoing list comprises all the pipe in the mill, whether water, solution, pulp or air, but it does not include the piping used in the heating system nor in connection with the refinery. It also includes the mill water-service pipe—a 4-in. line 1,200 ft. long.

All the thickener overflow pipes and main solution lines are 4-in. The 6-in. line is used on the gravity return from the presses to the No. 4 thickener. The large size is necessary on account of the small head available. Lunkenheimer all-iron clip gate-valves are used exclusively on all lines. Pipe work was started on Jan. 21 and completed Mar. 14. Five men composed the pipe-fitting gang. Wages were $3.25 for pipe fitters and $2.75 for helpers. A power-driven cutting and threading machine taking pipe up to 4 in. was available during the work.



REGRINDING DEPARTMENT

SUMMARY OF PIPING COSTS

Total cost of all pipe	$2,300
Total cost of valves	490
Total cost of fittings	600
Total cost of labor	1,050
Total cost of installation	$4,440

Of the total, labor comprises only about 24%. Valves and fittings cost about 50% as much as pipe. If we deduct the 1,200 ft. of 4-in. supply line containing almost no fittings, we get a figure of 60% for this ratio, which is nearer correct for straight mill work.

The mill water-supply line previously mentioned runs from the mine water tank to the mill water tank. For 100 ft. of its length the pipe lies in a box filled with sawdust. For 300 ft., rock cut was necessary to secure the required 4 ft. of cover. The balance is ordinary earth

excavation. Total cost for labor and material, from Table 2, is $2,291.58, or $1.91 per ft. This cost is rather high, as freezing weather was encountered before the work was completed. Under favorable weather conditions $1.70 per ft. could be achieved.

The mill water tank is 22 ft. in diameter by 20 ft. high, with sides and bottom of 3-in. British Columbia fir, and holds 50,000 Imperial gallons. It cost $464 f.o.b. Swastika. The bottom of the tank is 27 ft. above the ground. The substructure is of 10x10-in. timber on concrete piers. Costs are shown in Table 2.

Transmission Equipment and Machinery Installation

All bearings are of the ring-oiling type; split cast-iron pulleys are used throughout. A liberal factor of safety was allowed in all shafting, and the number of sizes used reduced to three—$1\frac{15}{16}$-in., $2\frac{7}{16}$-in., $2\frac{15}{16}$-in. The laid-down cost of all transmission equipment, excluding belting, was $1,534. Cost of belting was $2,050, making a total first cost for all transmission equipment of $3,584. Endless stitched rubber belts are used on all motor drives. All transmission and conveyor belting is of the best-quality rubber. Balata is used on the two elevators.

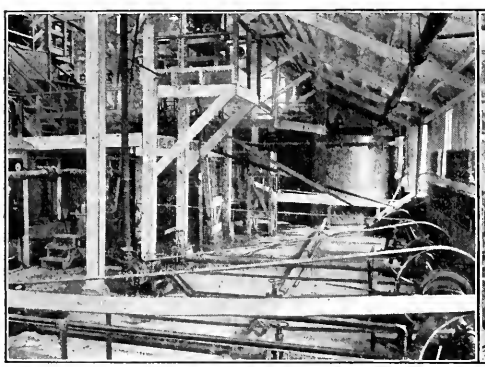
The data on piping and transmission already given are included under the heading of "Machinery and Equipment" in the main tabulation of cost given in Table 1.

In righting to carry it back over the 22 ft. of weighing platform and onto the down-grade, where gravity returns it to the shafthouse. A $\frac{1}{2}$-in. cable is used. The trestle is 950 ft. long, with a 10% grade for two-thirds of the way and 4% for the remainder. The track is 26-in. gage, using 20-lb. rails. The average height of trestle is 12 ft. and the hoisting speed is 150 ft. per min.

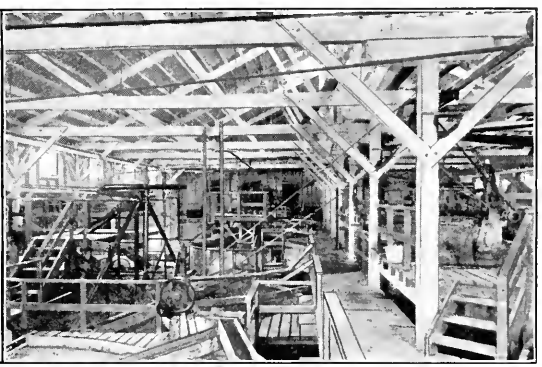
From the ore bin, holding 75 tons, the ore is drawn out through an arc gate into a 12x20-in. all-steel Buchanan jaw crusher set to 2 in. The product falls to a 14-in. 6-ply Balata-belt elevator with 12x7x7-in. manganese-steel buckets running 375 ft. per min. on 36-ft. centers.

The elevator delivers to a 30x60-in. Gates-type revolving screen running 20 r.p.m. and having $1\frac{1}{2}$-in. round perforations in $\frac{1}{4}$-in. plate. The oversize of this screen returns to a 10x16-in. all-steel crusher set to $1\frac{1}{8}$-in. with special smooth jaw-plates for fine grinding. The product from this machine drops to the same elevator and is returned to the screen. The undersize of the screen falls to a hopper, whence it is fed to the incline conveyor belt delivering to the cyanide-plant ore bin. This belt is 14-in. 5-ply rubber conveyor belting running at 125 ft. per min. on a 14° slope. It is driven by a separate motor.

The large crusher runs 250 and the small crusher 275 r.p.m. Each crusher is driven through a split friction clutch on a main lineshaft. Another clutch cuts out the countershaft driving the elevator, trommel and skip hoist.



PUMPING FLOOR, SHOWING ZINC FEEDER



INTERIOR OF THE TANK AND AGITATOR ROOM

In fact, this account is a blanket one covering everything that could not be properly charged to any of the other work orders. Besides all machinery proper, it includes the initial charges of pebbles and balls, amalgamating tables, all launders, elevator housings, platforms and walk-ways, guard rails and labor incident to trying out and adjusting machinery before it went into regular operation.

In the crusher station, labor forms 24% of the total; in the cyanide plant 17% and in the combined machinery installation, 18% of the total.

At the crushing station, floors and stairways were completed on Dec. 20 and machinery installation commenced on that date. The motor and shafting were turned over on Feb. 20 and the first rock was crushed on Mar. 8. The skip coming up the incline runs over a platform scale of 3 tons' capacity. The average weight of ore is 1.45 tons. The skip is then pulled up over a tipping device, and the empty skip acquires sufficient momentum

The crusher station has a normal capacity of 15 tons per hr. and often makes 20 tons when all conditions are favorable. The ammeter of the 50-hp. motor driving this department springs between 35 and 45 amp.

Description of the Cyanide-Plant Arrangement

The crushed-ore bin is flat-bottomed and holds 165 tons when filled up to the conveyor discharge. Of this, 85 tons will run out by gravity. From three chutes along one side of the bin, the ore is delivered by eccentric plunger feeders to a 12-in. conveyor belt traveling 75 ft. per min. This belt spills into the scoop box of a 16x72-in. Hardinge ball mill running 30 r.p.m. and set with $2\frac{1}{2}$-in. fall toward the discharge end. Sodium-cyanide solution titrating 2.5 lb. KCN per ton is added to the scoop box. The ball load is between 4 and $4\frac{1}{2}$ tons.

Under these conditions the capacity of the mill has been found to be between 85 and 90 tons per 24 hr., using 40 to 45% moisture. A lower moisture gives a

finer product but less tonnage. With 55 to 60% moisture a large quantity of coarse oversize is thrown out. It is hoped that by leveling up the mill, decreasing the speed to 29 r.p.m. and using a choke plate to raise the ball load, a considerable increase in capacity will be obtained. On medium-grade ore, $20 to $25 per ton, tube mills and cyanide plant will handle 110 tons. A screen test of the ball-mill feed and discharge is shown.

SCREEN TEST SHOWING BALL-MILL WORK

Feed (Average of 3 tests)	%	Discharge	%
On ⅜x1⅜	7.4	On 2-mesh	1.3
On 2-mesh	64.1	On 4-mesh	3.6
Through 2-mesh	28.5	On 10-mesh	7.1
		On 20-mesh	20.2
		On 60-mesh	18.7
		On 150-mesh	15.2
		Through 150 mesh, sand	11.0
		Through 150 mesh, slime	18.2

The ball-mill discharge is split between two duplex Dorr classifiers, each 20 ft. long, but except for the extra 4 ft. of length, standard machines. The rakes are lengthened 6 in. to prevent fine sand banking near the overflow. They are set on a slope of 2¼ in. per ft. The sand coming over the head end gravitates to the feed box of a 5x20-ft. tube mill equipped with a scoop of 26-in. radius. Pebbles are fed through the scoop and the load is kept 4 in. above center.

Moisture is kept at 40% of the total. The mills are provided with cast-steel heads, manganese-steel head liners and cast-iron gears. The shell liners are chilled cast iron with concentric ribs known as the Globe type. A set of shell liners weighs 10,500 lb. Exact power-consumption measurements are not at present available, but the ammeter registers between 70 and 80 amp. under normal conditions. A 100-hp. motor drives each mill through a 72x18-in. clutch pulley, thus leaving a margin for the use of manganoid balls if found desirable. Pulley centers are 22 feet.

The discharge from either tube mill may return to its classifier or to a 12-in. bucket elevator which raises it to two amalgamated copper plates from which the pulp returns to the classifiers. Each plate is 5 ft. wide and 30 in. long. Longer plates were tried out, but as the bottom one caught no gold and became corroded from the action of the cyanide, it was discarded.

Classifying and Filtering the Pulp

The dilution in the classifiers is kept between 5 and 6 to 1, the specific gravity of the ore being 2.7. The primary, or No. 1, thickener is a standard Dorr machine of heavy pattern. It makes one revolution in 8½ min. The pregnant solution overflowing it carries $4 to $5 per ton on medium ore and runs by gravity to a clarifying filter box containing twelve canvas vacuum leaves. Each leaf is 9 ft. 6 in. by 1 ft. 6 in. When precipitating at 375 tons per 24 hr., an average rate, this gives 70 sq.ft. per ton per hr. Experience shows that an allowance of 100 sq.ft. per ton per hr. would be better on Tough-Oakes ore.

An 8x10-in. vacuum pump delivers the clarified solution to the 16x10-ft. pregnant sump. A tipping-box with a counter measures the tonnage going into the tank. A 5½x7-in. triplex pump, with connection to Merrill zinc feeder on the suction side, forces the solution through two 36-in. 16-frame Merrill presses. The barren effluent carrying 2 to 6c. per ton can gravitate to No. 1 agitator, No. 1 thickener, or the 16x10-ft. barren-solution sump.

The vacuum and triplex pumps are belt-driven from the pump-floor lineshaft, which also drives two 3-in. Gwynnes centrifugal slime pumps. These pumps run 1,600 r.p.m. and handle the crushing and barren solutions. The crushing solution, being the overflow of No. 2 thickener, runs to a 16x10-ft. sump and is elevated continually by the centrifugal to the upper 20x10-ft. storage sump. The barren-solution pump is used only intermittently and is cross-connected so that it is available for handling crushing solution. A small motor-driven low-pressure air compressor is located on the pump floor. It has a capacity of 217 cu.ft. of free air per min. to 25 lb.

Returning to the primary, or No. 1, thickener, the underflow is elevated by diaphragm pump through 4-in. suction pipe to the first agitator at 40% moisture. The pump is of the constant-stroke variable-speed type, with a normal speed of 25 pulsations per minute. It is driven from the main lineshaft running the full length of the building. This shaft is supported on boxing mounted on the sides of the central row of posts. From it are driven all thickeners, agitators, diaphragm pumps and the sump elevator.

Agitation and Continuous Decantation Systems

The Dorr agitators are 16 ft. in diameter by 12 ft. high, with 6 in. fall between each tank. The arms make two revolutions per minute. Air is introduced at the top. The piping permits either crushing or barren solution to be added to secure the desired dilution—in this case 2.75 to 1. Present practice is to add cyanide sufficient to bring the solution in the first agitator up to 3 lb. per ton, or 0.15% KCN. Adding a portion of the cyanide to the tube-mill circuit is contemplated. As the experimental work indicated high acidity, dry lime was first added to the fine-ore bin. Practice showed the acidity to be not nearly so great, and it was found better to add the milk of lime to the thickeners. A protective alkalinity of about 1 lb. per ton, expressed as NaOH, is employed. The agitators dissolve about $2 per ton on medium-grade ore. The washed pulp from the last agitator will assay $1.60 to $1.80 and the same product in the final thickener discharge, $1 to $0.80c. There is no material difference between the plus and minus 200-mesh material. The solution going to waste assays 15 to 20c. per ton, which at 37% moisture means 7 to 12c. per ton soluble loss. This will undoubtedly be cut down when time has given an opportunity to perfect all details of the metallurgy. Thorough mixing of the solution and pulp entering the decantation thickeners is absolutely essential. The underflow solution value is at times double that of the overflow. The mill has not been running long enough to give representative figures for pebble and ball consumption, cyanide loss and cost per ton. Approximate estimates for the latter two items are 1¼ lb. and 2 lb. per ton.

The raw precipitate is worth $35 per lb. It is acid-treated in a wooden tank and then melted in a tilting furnace, using a No. 400 crucible. The resulting bullion is 600 fine in gold and 250 fine in silver.

The Houghton Copper Co., Winona, Mich., reports that during 1914 the sinking of the winze below the 820-ft. level was continued and bottomed at the 1,020-ft. level. The 620-ft. level was run north 383 ft. The 1,020-ft. level was extended 397 ft. to the south of the winze and 334 ft. to the north of the winze, and some good copper ground was encountered on both sides. Expenditures amounted to $23,440 and liabilities exceeded current assets by $7,650 at the end of the year. A mill test is to be made of about 7,500 tons of accumulated rock from development work.

Callow Flotation Process*

SYNOPSIS—The Callow pneumatic process is the result of development and modification of former systems. Its operation is described. Different oils affect different ores in various ways, but there is nothing but actual experiment to determine what will happen. The theory is that the process is an electrostatic one.

Early in 1909 I did a great deal of work with the Macquisten flotation process and was instrumental in the tube-plant installation at the Morning mill, at Mullan, Idaho. This work was followed by a large amount of experimenting on the different kinds of existing flotation processes, the outcome of which was the development of the pneumatic process.

The first application of pneumatic flotation for the treatment of ore was made at the mill of the National Copper Co., at Mullan, Idaho. The plant went into operation about Apr. 10, 1914. The flow sheet is shown in Fig. 1. Since that date, the process has been adopted by nearly all the other mills in the Cœur d'Alenes treating lead and lead-zinc ores, notably the Gold Hunter, Morning, Hercules, Bunker Hill & Sullivan, Caledonia, Last Chance, Hecla and Standard. The same process, too, has since been adopted by the Inspiration Copper Co., the Arizona Copper Co., the Anaconda Copper Mining Co., the Magma and other copper companies, and by the Silver King, Daly-Judge, Dusquesne, and El Rayo mining companies, on lead, zinc and other ores.

The Callow Floating Apparatus

The various elements composing the Callow process are shown in Fig. 2. In the mixer *A*, operated by compressed air, the oil, air and water are mixed and emulsified. In cases where the oil, or frothing agent, can be fed into the crushing or grinding machine, this mixer, or Pachuca tank, can be dispensed with, the tube mill discharging direct to the separatory cell.

The initial or roughing separatory cell *B* consists of a tank about 9 ft. long and 24 in. wide, with a bottom inclined at from 3 to 4 in. to the foot. It is 20 in. deep at the shallow end and 15 in. deep at the other end. It may be built of either steel or wood, but wood is preferable. Fig. 3 shows the cell in detail. The bottom of the tank consists of a porous medium made of four thicknesses of loosely woven canvas twill, properly supported by a backing of perforated metal to prevent its bulging when under air pressure. Through this porous medium compressed air is forced by a blower. Porous brick or any other ceramic material that will give the necessary fine subdivision to the air may also be used. Some of these have been tried out, but for practical and mechanical reasons the loosely woven canvas twill seems to serve all purposes better than anything else.

The space underneath this porous bottom is divided into eight compartments, each connected by an individual pipe and valve with the main air pipe. By this means the air pressure to each compartment can be regulated (by throttling the valve) to correspond to the varying hydraulic head within the tank, and so as to discharge a uniform amount of air throughout the length of the bottom. A pressure of from 4 to 5 lb. is commonly used, each square foot of porous medium requiring from 8 to 10 cu.ft. of free air per minute.

Each longitudinal edge of the tank is provided with a lip and an overflow gutter for the reception of the froth discharged. The lower end of the tank is furnished with a spigot discharge fitted with a plug valve operated by a float, to maintain a uniform water level within the tank

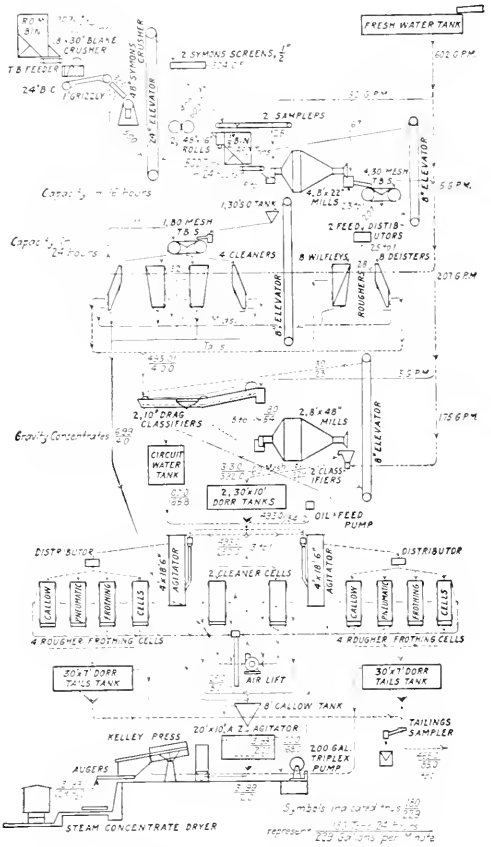


FIG. 1. NATIONAL COPPER MINING CO'S MILL

and thus, in turn, maintain a uniform and constant discharge of froth under all the varying conditions of feed supply incident to practical milling operations. The water level may of course be varied, but is usually maintained at about 10 to 12 in. below the level of the overflow lips.

The tailings are discharged through the spigot, and the frothy concentrate is conveyed to the cleaner separatory cell *C*. This cleaner cell is a machine of the same construction as the rougher. In operation, however, it

*Excerpts from a paper by J. M. Callow, Salt Lake City, Utah, to be presented at the February, 1916, meeting of the American Institute of Mining Engineers at New York.

usually has a lower air pressure. The tailing from the cleaner is returned to the original feed, a closed circuit thus being maintained. The concentrate from the cleaner is the finished product.

The machines may be run either in parallel or in series without any sacrifice in the capacity for a given number of cells. Recent experience goes to show that on some ores the series treatment gives slightly cleaner tailings; on others it does not. It is not necessary to extend this arrangement of cells beyond two cells in series. In a heavily mineralized ore this arrangement is decidedly advantageous, and in such a case the rougher concentrate might be of high enough grade to dispense with the cleaning operation. The froth from the second cell in the series might be returned to the original feed, in the same way that the tailings are returned from the cleaner when practicing a roughing and cleaning operation. A number of such combinations are possible.

At the mill of the Inspiration Copper Co., Fig. 4, the feed goes to 12 primary roughers, the tailings from which are classified into sand and slime, the sand going to tables and the slime to 12 secondary roughers. The concentrate from both the primary and secondary roughers goes to four cleaner cells, and the tailings from the cleaner cells are pumped back into the circuit.

Froth Formation and Pulp Density

The froth is generated as the result of injecting the finely divided air into the bottom of the already emulsified pulp; it continues to form and to overflow as long as it is furnished with pulp of the proper consistency, adequately mixed with the right quantity and kind of oil or frothing agent. Measured from the water level within the tank, the froth produced may be from 14 to 16 in. thick and will be more or less voluminous, coarse or fine-grained, dry or watery, according to the character of the ore and the kind and quantity of oil introduced. The condition of the froth may be varied, therefore, by changes in the kind and quantity of oil used and the quantity of air injected. In some ores rich in sulphides, and where a comparatively low-grade concentrate will suffice, the cleaning cells may not be necessary, but on low-grade ores having a high ratio of concentration and when a concentrate of extreme cleanness and of maximum grade is required, a cleaner is desirable.

The pulp to be treated may be of varying density, from 2½ of water to 1 of ore, up to 5 or 6 to 1. For a mixture of sand and slime, the former ratio is preferable, but for pure slime, minus 200-mesh, the larger proportion of water is allowable. The particular density is not a matter of so much importance as the supplying of pulp of uniform density, since each variation in the density of the pulp requires a readjustment of the oil supply, the quantity of oil increasing in proportion to the increased volume of the pulp, independent of its solid contents.

The Oils Used and Froth Character

The oils used may be broadly divided into "frothers" and "collectors." The pine oils are good frothers, and coal tar and its various subdivisions are good collectors. On some ores crude pine tar will in itself combine the properties both of frothing and collecting; on others, this may have to be enriched by the addition of some one of its more volatile constituents, such as refined pine oil, turpentines, or wood creosote.

Generally speaking, the coal-tar products are poor frothers, and to get a sufficient volume of froth to insure a high recovery, it is often necessary to add refined or crude pine oil, creosote, etc. At the Inspiration mill, for instance, the mixture is 80% crude coal tar, 20% coal-tar creosote; at another plant on similar ore, 45% El Paso coal tar, 40% coal-tar creosote, 10% creosol and 5% pine oil. At Daly-Judge a mixture of 40% crude coal tar, 40% creosote and 20% pine oil was used. In the Cœur d'Alenes on zinc ore straight wood creosote was used; on the ore of the National Copper Mining Co., plain turpentine will work, but pine oil is better.

At Inspiration, from 1½ to 2 lb. of the mixture per ton of ore was used; at Daly-Judge, 1 to 1½ lb.; and at the National, $\frac{3}{10}$ lb. of oil is sufficient. In the experimental work at another plant the oil consumption was approximately 1 lb. of mixture per ton; but since the entire plant has been in operation, and the circuit water reclaimed and used over again, the oil consumption has dropped to 0.35 lb. At present the proper kind or kinds of oil and the quantity requisite can be determined only by experiment; no scientific way has thus far been found.

The stability of the bubbles depends to some extent upon the oil used and the nature of the gangue in the pulp

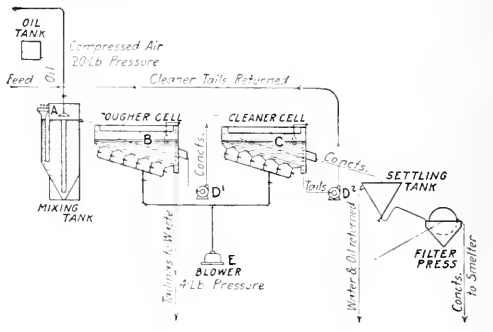

FIG. 2. CALLOW PNEUMATIC PROCESS

treated. Pine oil makes a brittle froth, which dies immediately on arriving at the surface. Creosote and light oil make a more elastic envelope, which at times will expand into bubbles 3 or 4 in. in diameter before bursting. Pine-oil bubbles are rarely over ¼ or ½ in. in diameter. Castor oil, olive oil, candle-makers' oil (oleic acid), palm oil, sperm oil and other oils of a lubricating nature have in general been replaced by oils more or less soluble or miscible in water—such as turpentine pine oil, and all the coal- and wood-tar distillations. The extremely volatile hydrocarbons, as naphtha, gasoline, ether and alcohol, seem to be of little use except as means for making the pitchy ingredients of coal and wood tars more soluble or miscible. A large, coarse and elastic bubble seems necessary to the recovery of coarse-grained mineral, but for the very fine and colloidal mineral, a small and comparatively brittle bubble is necessary.

The National Copper Mining Co., using approximately 950 cu.ft. of air at 4 lb. pressure, and treating 500 tons per day on eight roughers and two cleaners, required 35 hp.; this shows a requirement of 3.5 hp. per cell, equivalent to 12.53 tons per hp., or 1.25 kw.-hr. per ton.

Another company using approximately 9,600 cu.ft. of air at 5 lb. pressure and treating 2,100 tons per day on 48 roughers and 12 cleaners, requires 240 hp., equivalent to 3.5 hp. per cell, 11.45 tons per hp., or 1.56 kw.-hr. per ton. The experimental plant of the Inspiration Copper Co., using approximately 950 cu.ft. of air at 5 lb. pressure and treating 200 tons per day with four roughers and one half-size cleaner, required 24 hp.; deducting 4 hp. for two 2-in. centrifugal pumps, the figures become 4 hp. per cell, 10 tons per hp., or 1.79 kw.-hr. per ton. A maximum figure would be 2½ kw.-hr. per ton of feed, using 5 to 5½ lb. air pressure, generated by Roots or Connersville positive blowers.

The oil mixtures in use cost from 1.25c. per lb. up to 3c. per lb., depending on the percentage of creosol and other high-priced oils used; on most ores, 1½c. per lb. is a safe average figure, and a consumption of 1 to 1½ lb., or from 1.25c. to 1.5c. per ton of feed, averaging 2½c. would be a safe estimate.

Labor will vary, of course, with the size of the plant. At one plant consisting of 60 cells, two men per shift operate the entire plant, equivalent to a cost of 1¼c. per ton. One man per shift on a 250-ton plant means a cost of 5.4c. per ton. Assuming a life of three months per blanket, a capacity of 50 tons per cell, and an allowance for repairs to blowers, motors, pumps, etc., we have ½c. per ton as a liberal allowance.

With power at 1c. per kw.-hr., and a consumption of 2½ kw.-hr. per ton, the cost would figure 2.5c. per ton of feed. The estimated cost on a 2,000-ton flotation plant, or larger, would be approximately as shown in the table.

FLOTATION COST ON A 2,000-TON PLANT

	Per Ton, Cents
Labor	1.25
Oil	2.50
Maintenance	0.50
Power	2.50
Total	6.75

On a plant of 250 tons the extra labor costs per ton would bring it up to approximately 10c. per ton of flotation feed. Actual figures from a large plant treating over 2,000 tons by flotation gave 6.1c. per ton. The flotation feed in this case represents 60% of the crude-ore tonnage, making the cost 3.5c. per ton of crude ore treated.

The Reasons for Flotation Phenomena

So far no satisfactory explanation of flotation phenomena has been advanced. At my instigation and under my direction, a large amount of research work has been done in an endeavor to formulate some logical explanation of the phenomena, and perhaps to find some scientific way of conducting flotation experiments in place of the empirical methods now in vogue. Although the latter object has not yet been attained, still these experiments have resulted in the formulation of a theory that appears to be well grounded and that may prove of interest and value to others engaged in this art. This theory refers flotation ultimately to electrostatic action.

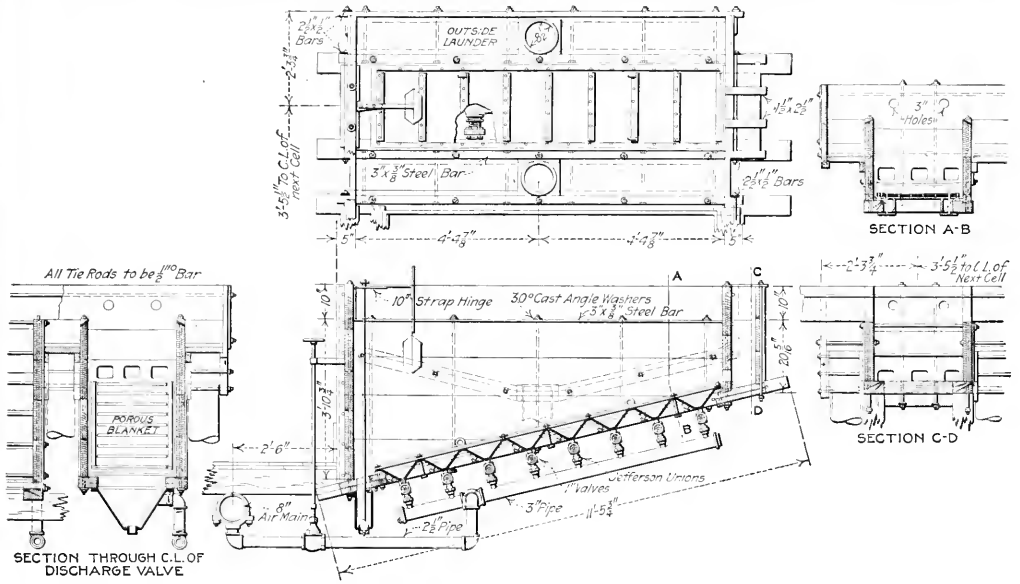

FIG. 3. DETAILS OF THE CALLOW FLOTATION CELL

Much work has been done at the Mellon Institute, at Pittsburgh, under the direction of Dr. Raymond C. Bacon, and lately by James A. Block at the station of the United States Bureau of Mines in Salt Lake City. The result of all of this work is summed up in the following statement:

In considering the connection between flotation phenomena and the physical properties of the minerals concerned, there are two parallelisms:

First—It has been noticed for some time that the minerals that floated were not easily wetted by water, while those that were easily wetted did not tend to come up with the froth.

Second—There is a parallelism between certain electrostatic characteristics and the flotation properties of ores.

In the first-mentioned theory, surface tensions and contact angles should be considered. Certain minerals, such as galena, will float on the surface of still water, while gangue particles, since they possess a greater adhesive attraction for the water than the water's cohesive attraction for itself, will be drawn through the surface film into the interior, and sink because of their greater specific gravity. These properties of floatable minerals and gangues are increased by the presence of oil and acid. Oil sticks to galena with greater tenacity than it does to silica, and an oil surface is still less easily wetted than a galena surface. The acid in the water causes a still greater

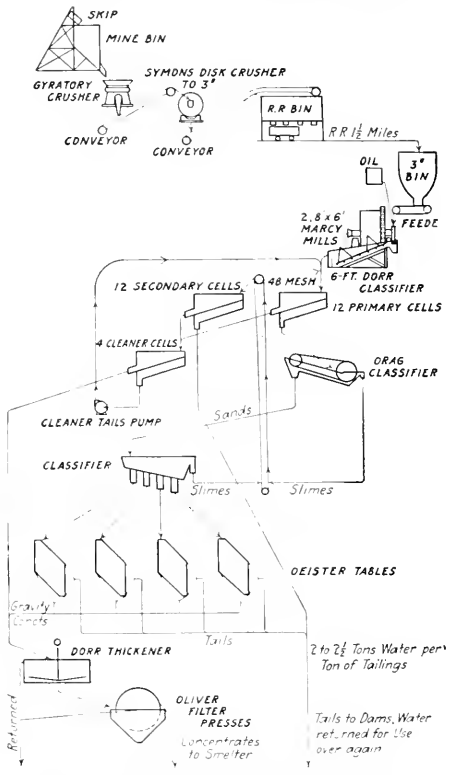

FIG. 4. INSPIRATION COPPER CO.'S MILL

difference in the various surface tensions. This, it seems, is without question the explanation of the action in the Macquisten process, in which the ore particles are lifted to the surface where they can be removed by skimming off the surface layer of the liquid.

With reference to the second parallelism, it has been noticed that extremely small amounts of certain colloidal impurities, such as saponin or tannin, were detrimental to flotation; while others, such as Congo red and methylene blue, did not interfere and were, if anything, beneficial. In classifying these, the injurious ones generally came under the head of what physical chemists call electronegative colloids, while electropositive colloids were not harmful. Suspended particles will generally migrate when placed in an electric field, and this classification comes naturally from the direction of their migration. This migration is called electrophoresis, or electrical endosmose, and is the result of the formation of contact layers around the particles by the liquid containing them, very similar to the formation of surface films when liquids come in contact with air. These contact films almost invariably have a difference of potential between their inner and outer surfaces. An air-water contact film has, for instance, a difference of 0.055 volt, and other contact films have similar charges. This causes the particles to act like charged solids and to be attracted by electric charges of opposite sign.

The charges on solids and nonmiscible liquids can be conveniently studied on the stage of a microscope.

This work naturally led to the study of the charges exhibited by various ores and minerals, and in that work an interesting parallelism was observed—namely, that floatable minerals seemed to have positive charges and non-

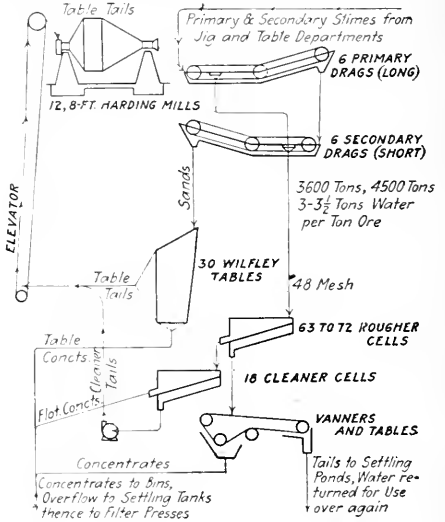

FIG. 5. ARIZONA COPPER CO.'S MILL

floatable gangues, negative charges. Some gangues were found with positive charges, but they were characteristically hard to handle, having a tendency to come up with the froth. These charges sometimes vary with the acidity or alkalinity of the liquid, and this variation is not inconsistent with the effects of acidity or alkalinity on the flotation of ores.

It has been noticed that these electrostatic properties depend on the condition of the surface of the particle and not upon the composition of the mass. For instance, lead oxide, which is ordinarily negative or neutral, when covered with a sulphide coating takes upon itself a positive charge.

Effect of Contact-Film Charges

Recent investigations on the coagulation and deflocculation of slimes, on the coagulation and dispersion of colloids and along similar lines show that these contact-film charges, although small, have an important bearing on the dispersion or coherence of particles suspended in liquid mediums. In fine suspensions and in colloidal solutions, these charges may often be neutralized by the introduc-

tion of oppositely charged ions, precipitation generally taking place whenever these charges fall below certain limits. Oppositely charged contact films have a general tendency to coalesce, while similarly charged films, if their charges are great enough to overcome natural cohesiveness, do not seem to coalesce, but to repel each other, and if the weight of the particles is small enough in relation to their size and surface, permanent dispersion will take place, the particles distributing themselves through a liquid in much the same manner that gas will fill a container.

In view of the above observations, it seems possible that flotation is the result of difference in polarity in the

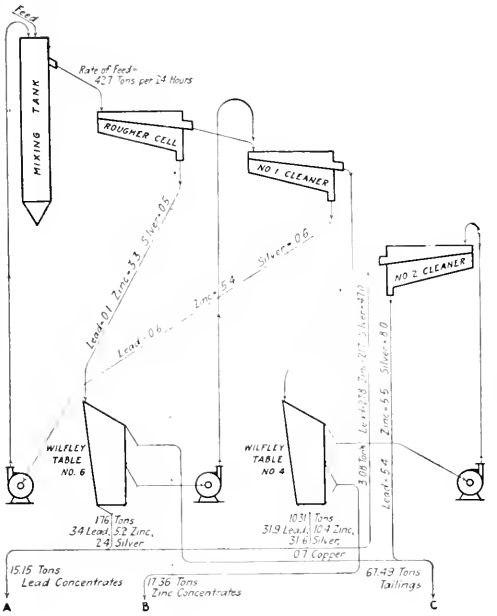

FIG. 6. FLOTATION AT THE DALY-JUDGE MILL

A	B	C
27.8 Pb = 84.95% total lead	3.9 Pb = 13.82% total lead	0.1 Pb = 1.37% total lead
12.1 Zn = 18.07% total zinc	42.4 Zn = 72.61% total zinc	1.4 Zn = 9.32% total zinc
31.4 Ag = 47.27% total silver	27.8 Ag = 48.02% total silver	0.7 Ag = 4.71% total silver

4.0 Insoluble	7.9 Fe	
	3.2 Insoluble	

charges on the various ore particles and on the bubbles. Since oil contact films and air contact films have both been proved to have negative charges, the positively charged minerals will adhere to either. The bubble mantles in a flotation machine are undoubtedly composed of oil or of oil in emulsion, since pure water alone will not froth. The same forces, then, that cause oppositely charged colloids to agglomerate and precipitate, cause the minerals to adhere to the oil-covered bubbles; and the same forces that keep the particles of an oil emulsion dispersed, keep the gangue particles repelled from the bubbles

Expressed briefly, the theory is as follows:

That oil flotation is an electrostatic process. It is a scientific fact that when a solid particle is suspended in water, the water will form around the particle a contact film which generally possesses an electric charge, the amount and polarity depending upon the nature of the surface of the particle and the electrolyte in which it is suspended. The presence of these charges can be demonstrated by the fact that the particles possessing them will migrate when placed in an electric field. It has been demonstrated that floatable particles have charges of one polarity (positive), and that nonfloatable particles have charges of the opposite polarity (negative); that the froth is charged negatively and so attracts the positively charged or floatable minerals and repels the negatively charged or nonfloatable ones. It is this, it is believed, that causes the floatable minerals, galena, sphalerite, etc., to adhere to the froth, and the gangue minerals, silica, etc., to remain in the liquid where they can be discharged as tailings.

A Word from Russia*

I finally left London on Apr. 5. I had been prepared to start on Mar. 19, but a few days before that, the wound in my leg, which I had received in the Caucasus, began to trouble me. It grew a little more painful every day, until on the 18th I consulted a surgeon, who said that an abscess was forming where the bullet was still lodged Consequently, I had to go into a hospital for an operation to have the bullet removed. This delayed me practically two weeks.

After I had reached Petrograd, I stayed there 10 days on business and then went to Moscow for a two-day visit. From there I went to Batoum and thence to our establishment at Danzoul, 40 mi. farther south. The Turks had voluntarily retired from the vicinity of our property early in March, on account of their rear being threatened. Much to my surprise, they had done no great material damage to the works. It is nothing short of marvelous that they had not done so. The local natives, however, had looted all of the private houses and had stripped them absolutely bare. The upholstered furniture and mattresses, which they did not wish to carry away with them, had had their coverings torn off. The only personal belonging that I recovered was the Brunton compass presented to me by the boys at the Braden mine. This had been found by a Russian soldier on a mountain side several miles distant from my house, where it had evidently been dropped unintentionally.

Besides looting the houses, the natives had done much willful damage to them—some not having even a door or window left. At the mine, as well as the reduction works, the warehouses had been looted. They had taken about 10 tons of explosives, all hand tools and instruments of every description, in addition to such material as leather and vanner belts. But this is all as nothing compared to what they might have done with a few matches or with a few boxes of dynamite. It is true that before going away they placed several mines, including two under my house; but these were probably for future use.

The collecting again of a staff and the making of the necessary repairs will be a big undertaking. However, nothing can be done until the Dardanelles is opened and the war with Turkey as good as settled. Fortunately, all of the old staff members whom I would want to re-

*Excerpts from a letter from R. T. White, of the Caucasus Copper Co., reprinted from "Teniente Topics." The letter is dated May 16, 1915, and sent from Tiflis.

engage, are anxious to return; but now there is very little labor available, and besides, general conditions are not such that we could do anything at the present moment.

Two weeks ago the commandant of the province of Batoum issued orders that all foreigners should be excluded from the district; so for the present I am obliged to stay in Titlis, where I am simply waiting to see what is going to turn up next. I am in hopes that the order will be sufficiently modified within a few days so that I can return to Danzoul.

The St. Paul Electrification

C. A. Goodnow, assistant to President A. J. Earling, of the Chicago, Milwaukee & St. Paul Ry., in charge of the electrification work, states concisely the following advantages to be expected from electrification:

Our new electric locomotives have a capacity for hauling 3,200 tons on a 1% grade, while the maximum capacity for one of our steam locomotives on a 1% grade is 1,900 tons. In other words, our trainloads can be increased about 68% by electrical operation.

A Mallet steam engine costs 15c. to 25c. per mi. for repairs, while repairs to our electrical engines, so far as we can judge, will approximate 4c. per mi.

The first stretch of track on which electric engines will be put in service Dec. 15 comprises only one division—from Deer Lodge, Mont., to Three Forks. When the second division—from Three Forks to Harlowton, Mont.—is completely electrified we shall be able to judge how much the company will save from the reduction of interdivision expense. This will be a very considerable item. A steam locomotive, in common railroad practice, is not run through from one division to another. At the end of the division a steam engine must be cleaned and overhauled. The flues may be leaking, a cylinder may be hot or the firebox may be out of order—all reasons why it is impractical to run a steam engine from one division to another. An electric engine, on the contrary, may safely be run indefinitely without being laid up at division points.

Through what is called regenerative braking, moreover, a train on the down-grade is made to return for subsequent use 21% of the electric power required to move a train of similar tonnage up the same grade. This was proved in tests which I witnessed on the Butte, Anaconda & Pacific electrified railroad.

By electrification we eliminate fuel trains carrying company coal, and we do away with the necessity of maintaining wayside coal and water stations and cinder-pit expense.

Flotation at Idaho Springs

The Oneida-Stagg Mining and Milling Co., of Idaho Springs, Colo., is planning additional development calculated to open up more ore and facilitate the handling of orebodies now available. The mill, which was originally designed to treat ore by the continuous-decantation system of cyanidation, has been remodeled and is now equipped to treat 50 tons a day by oil flotation. It is estimated that the milling cost is about 85c. per ton. The cost of the oil is reported to be about 3c. per ton of ore treated.

The ore is delivered to a grizzly, the fines passing to the mill bins and the coarse to a Beales crusher and thence to the bins. The ore is delivered automatically to the stamps, and the pulp from the stamps passes to the concentrating tables. The concentrates are delivered to storage bins by a screw conveyor. The middlings pass to a Dorr thickener. Slimes and sands are delivered to a Dorr classifier, from which the sands go to waste and the slimes to a Dorr thickener.

The feed for the flotation machine is taken from the thickener, and the oil is added before the feed reaches the machine. The concentrates from flotation join the table concentrates on the screw conveyor. The surplus water from the conveyor and the tailings from the flotation machine are returned to the Dorr thickener. The concentrate bin is provided with a steel floor covering steam pipes, so that the concentrates may be relieved of moisture before shipping.

Revision of Mining Laws

The Utah chapter of the American Mining Congress has recently proposed that mining men of the West who are unable to visit Washington on Dec. 16 should ask the heads of their companies in New York to send somebody to represent them.

E. B. Kirby has made the excellent suggestion that mining men who are unable to attend should send brief telegrams expressing their opinion, to be read in the convention. Such telegrams, if sent on Dec. 14 or 15, should be addressed to F. F. Sharpless, secretary, in care of the U. S. Bureau of Mines, Washington, D. C.

Both the secretary of the Mining and Metallurgical Society and the Director of the United States Bureau of Mines have received many inquiries from oil men and coal men with regard to consideration of revision of the laws pertaining to oil and coal lands. The purpose of the forthcoming convention is especially to urge revision of the laws applying to metalliferous deposits. However, the position of the mining societies is that the mining laws should be revised in whole, not merely in part, and if it be shown that the laws governing coal lands, oil lands, etc., should be correlated with those governing metalliferous deposits, the contention will probably receive a hearing.

The headquarters of the convention will be in the Raleigh Hotel. The management of that hotel has granted special rates to members of the convention. Representatives attending should establish their membership by registering promptly.

It has been impracticable to secure any special railway rates on account of the small number attending from any one city, but a special Pullman will be run from New York over the Pennsylvania R.R. for the accommodation of members and delegates. This will leave the Pennsylvania Station, New York, at 12:30 night, Dec. 15, arriving in Washington at 7:10 a.m. The car will be open after 10 p.m. The corresponding Pullman will leave Washington at 12:30 night, Dec. 16, arriving in New York 7:13 a.m., Dec. 17. Anyone desiring reservations on either of these trains is to notify the secretary, F. F. Sharpless, 52 Broadway, as soon as possible.

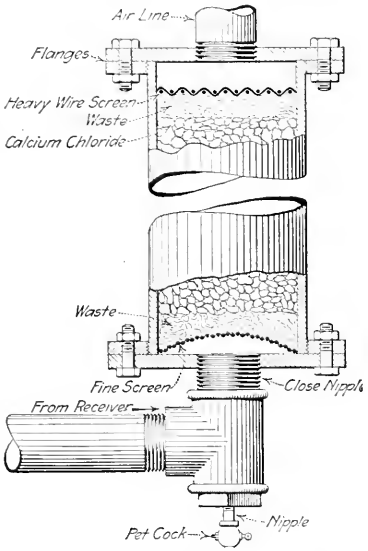
Coal Deposits on the Danish Island of Bornholm are being investigated by Danish and Swedish engineers with a view to their commercial exploitation.

Details of Practical Mining

Dryer for Compressed Air

By Charles Labbe*

Trouble is sometimes experienced with the moisture contained in compressed air. It rusts pipes, joints and valves and results in the latter frequently sticking and freezing. This trouble can be eliminated if the air be passed through a dryer containing calcium chloride or some other deliquescent material. A simple installation is the following, which may be made entirely of pipe fittings, available at nearly every mine: Use a piece of 6- or 8-in. pipe 3 or 4 ft. long (I used a 6-in. pipe, 4 ft. long, for a 10x12-in. compressor) and on each end screw



DRYER FOR COMPRESSED-AIR LINES

a flange to which is bolted a 2-in. flange or other size to fit the air main. At the bottom of the main chamber (the 6- or 8-in. pipe) place a concave wire screen (I used a 24-mesh screen over which was placed about 1 in. of cotton waste to keep the calcium chloride from running through). Next fill the chamber with calcium chloride to within about 3 in. of the top, then 1 in. or less of cotton waste, so that none of the salt will be carried into the piping, and place a heavy wire screen (about $\frac{1}{4}$-in. mesh) over the waste to keep it in place. At the lower part of the dryer a tee is connected by means of short nipples to the dryer flange and to a pet-cock which may be used as often as desired for draining. The dryer should be connected on the outgoing pipe of the air receiver. The calcium chloride has to be replaced from time to time, but this may be readily done by removing the flanges.

*Nelson, Nev.

Tempering Piston-Drill Bits

In a series of comparative tests of piston-drill bits made at the School of Mines, University of Missouri,[1] the following method was tried for tempering drill bits, and better results were secured than with any other method.

The graphite crucible containing a small quantity of salt (NaCl) was placed on the forge and the salt melted. The melting point of salt is about 800 deg. C., which is slightly above the critical temperature of the drill steel used. The steel to be tempered was placed on end in the crucible, the molten salt covering the bit to a depth of about $1\frac{1}{2}$ in. The steel was left in the salt until, on removing, the salt no longer clung to it; in other words, until the steel had reached the temperature at which salt melts. The salt itself got considerably hotter than its melting point, but by watching the steel carefully, it was possible to remove it almost immediately after it had attained the proper temperature.

The steel was plunged directly into a bucket of freshly drawn water. The temper obtained in this manner was believed to be as nearly uniform as it would be possible to get with any method without the use of much more elaborate apparatus. The bits were hard and tough and stood up remarkably well. It was not uncommon to drill from 12 to 15 ft. in hard granite with one piece of steel which certainly indicated a good temper for the bit.

Getting Powder to the Miner

Different schemes have been observed for furnishing the miner with powder. In some mines a special blasting shift is put on. Undoubtedly powder can be saved in this way, as the greater experience these men get in treating the ground in question fits them to judge more accurately the minimum amount of powder necessary.

It is less complicated, though more wasteful of powder, to have a man find out from the miners at the beginning of the shift the amount of powder and primers they will need. This information he sends to the surface where the various orders are made up in the powder house. Toward blasting time the orders are sent below in gunny sacks to an underground magazine where each miner or his helper can get his own as shown by his employee's number on the sack.

Sometimes enough powder is kept underground and each miner sends his helper to the magazine for what he needs.

The Kv.-A. Convention

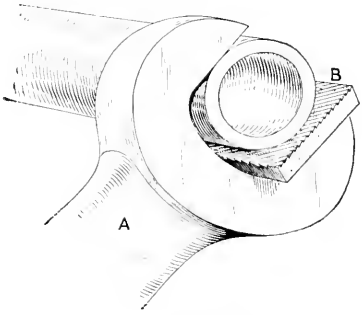
In alternating-current work there is generally a lag between the current and the voltage, so that multiplying the amperage by the voltage does not give the correct power in watts. For a three-phase current, amperage $\times$ volts $\times \sqrt{3}$ = kv.-a, called kilovolt-amperes. If this

[1]Bulletin of the School of Mines and Metallurgy, University of Missouri, August 1915.

kv.-a. is multiplied by the power factor the result is the power in kilowatts (kw.). This can be represented by a triangle of which the kv.-a. is the hypotenuse and the kw. the long horizontal length, in which case kw. $\times$ cos $\angle$ = kv.-a. Whenever the kv.-a. or the kw. are specified, the power factor should always be given to obviate any chance of misapprehension.

Emergency Pipe Wrench*

While doing erection work a considerable distance from where tools could be obtained it was discovered that no pipe wrench large enough to handle a 2-in. pipe could be found on the job. The difficulty was overcome, however, as shown in the illustration. A solid wrench *A*, slightly larger in the jaw than the diameter of the pipe, was secured. The space between the pipe and the jaw was



A PIECE OF FILE FORMS THE GRIP

then filled by inserting a short piece of file *B*. The wrench was then operated in the direction of the arm, the file teeth taking hold as well as a pipe wrench, and the work was quickly completed.

Draftsman's Erasing Knife†

A rather clever and efficient little scratcher for the draftsman's use can be made from an old safety-razor blade and a 5- or 6-in. piece of $\frac{1}{8}$-in. copper wire. The wire should be split longitudinally for about $\frac{1}{8}$ in. by a jeweler's hacksaw, and a portion of the blade soldered into position in this slit, using a small blowpipe with a candle as source of heat, or a blue gas flame.

Any soft solder and its appropriate flux, as tin and muriatic acid, will work, but the most convenient solder and flux is "Solderall," which is a pure tin, finely ground, mixed with flux and put up in tubes ready for use. After soldering, the steel may be ground to any desired shape, giving a very thin, sharp edge, which will remove an inked line without cutting the paper or tracing cloth.

Incidentally it may be mentioned that "Solderall" is part of every chainman's equipment in the surveying district of Arizona, it being supplied by the surveyor-general, together with a number of sleeves just fitting the tape used. If a break occurs in the field, the men fit the broken ends into a sleeve, put "Solderall" at both ends of the sleeve and hold a match under it.

The Hoisting Rope Question*

The matter of governing the use of hoisting ropes is one of great importance, inasmuch as in most mines the lives of many men for several hours in each day depend on the reliability of the ropes used to hoist the cages. This is well recognized, and in general the greatest care is exercised in inspecting the ropes and maintaining them in good condition. It is furthermore true that inspection of a rope is relatively simple, that the precautions against accident are easy to take and, particularly, that a good wire rope gives ample warning of being unsafe.

Nevertheless, distressing accidents do occur from failure of ropes, and practice in the methods of caring for, inspecting and retiring hoisting ropes varies greatly. Standardization is highly desirable in regard to the methods of rope fastening, to the ratio between rope and sheave diameters, to safety factors and the method of determining them and to the basis on which a rope should be retired from service. However, there were not obtainable, in this country at least, sufficient accurate data on which regulations as specific as desirable might be based.

In order to obtain technical information as complete as possible on this question of hoisting ropes, the leading rope manufacturers of the country were consulted and finally a conference was had at which representatives of the several manufacturers met with the chairman of the committee and discussed the matter in detail. Some of the most perplexing points were then referred to a committee of the manufacturers for further consideration. The general discussion and the report of this committee have brought out facts that are of great interest and technical value aside from their bearing directly on the question of safety.

Safety Factor

In considering first the matter of safety factors, questions arise as to what safety factor to require, what stresses to include in the divisor in determining such factor, and how to ascertain the dividend, or ultimate strength of the rope. As regards ascertaining the ultimate strength of the rope, the committee is convinced that it is both safe and economical to rely on the tables furnished by manufacturers in their catalogs or elsewhere. Since the strength of the material in the wire and the method of assembling the wires into the rope both have a bearing on the rope's strength, it is plain that there is much opportunity for variation. Nevertheless the product turned out is remarkably uniform and reliable. Each individual rope is not tested, but tests are made on ropes of the several constructions and classes of material, and these are constantly checked. The tables in the catalogs perhaps rather understate than overstate the strength of a rope, but the error is slight, is on the right side so far as safety is concerned and is not of enough consequence to affect seriously the matter of costs.

The total stress in a hoisting rope is made up of several factors. The most important of these is the dead load of the vehicle, its contents and the rope itself. Added to this is the stress caused by starting and acceleration; this may be extremely high if the hoisting engineer is reckless, careless or ignorant; the practice of starting with a slack rope, sometimes followed where the hoist is under-powered for its work, may put extraordinary tension on the rope.

*Abstract from "Rules and Regulations for Metal Mines," by Ingalls, Douglas, Finlay, Channing and Hammond; Bulletin 75, United States Bureau of Mines.

Then there is the bending stress when the rope takes the curve of the sheaves, drum or reel or straightens out when leaving it. These three stresses are more or less calculable. Finally there are extraordinary stresses, such as those that occur when a shaft vehicle is pulled at full speed into a constriction of the shaft or when it is overwound. These of course may be of such magnitude that no rope could be expected to withstand them. It is also true that high-speed hoisting is harder on a rope than low-speed and causes more rapid deterioration—a consideration of importance in determining safety factors.

Permissible Hoisting-Rope Safety Factor Difficult to Figure

What stresses shall be considered in calculating the rope safety factor? While those due to acceleration and bending are determinable, they are not easily so, and it seemed to the committee that it was desirable to make the provisions of this code easy of analysis and enforcement. It was therefore decided to calculate the safety factor on the basis of dead load only and make it proportionately greater.

It is evident that with so many different elements affecting the service of a rope, no single safety factor could be selected that would be effective and fair for all cases. It was the sense of the majority of the manufacturers' representatives that the service of ropes should be classified, taking account of the depth of the shaft, whether it be vertical or inclined, wet or dry, whether the hoisting be fast or slow, whether the water be "acid" or not, etc., and that the safety factor and other requirements should be varied to suit these several classifications. Such a course would be theoretically correct, but would result in provisions too complicated for a code such as this. The code therefore imposes a minimum safety factor for all installations and another below which no rope shall fall and remain in service; very deep shafts it exempts altogether.

However, the manufacturers' committee, of which mention has been made, went carefully into some phases of this matter and compiled some tables that represent good practice and constitute excellent rules for mining operators to follow. In the first place, the safety factor is varied according to the depth of the shaft, one is specified for new ropes and another below which no rope shall be allowed to fall. The factor is to be determined by dividing the manufacturers' figures for breaking strength by the dead load.[1]

TABLE 1. HOISTING-ROPE SAFETY FACTORS FOR VARIOUS DEPTHS OF SHAFTS

Length of Rope, Feet	Minimum Safety Factor for New Rope	Minimum Safety Factor When Rope Must Be Discarded	Percentage Reduction
500 or less	8	6 4	20
500 to 1,000	7	5 8	17
1,000 to 2,000	6	5 0	16⅔
2,000 to 3,000	5	4 3	14
3,000 and over	4	3 6	10

The several factors given in Table 1 are based on an actual safety factor of four and are made greater for the shallower shafts because in them the acceleration stresses and a good many of the possible extraordinary stresses are normally greater. In deep shafts it is well recognized that the spring of the rope acts to eliminate the shock of starting and to decrease the stresses of acceleration.

Then for the several depths of shaft, or lengths of rope in the shaft, maximum permissible hoisting speeds are specified. These are given in Table 2.

TABLE 2. PERMISSIBLE HOISTING SPEEDS WHEN SPECIFIED SAFETY FACTORS ARE USED

Length of Rope in Shaft, Feet	Maximum Hoisting Speed, Ft. per Min	Length of Rope in Shaft, Feet	Maximum Hoisting Speed, Ft. per Min
500 or less	1,200	2,500 to 3,000	2,500
500 to 1,000	1,600	3,000 to 3,500	2,750
1,000 to 1,500	2,000	3,500 to 4,000	3,000
1,500 to 2,000	2,000	4,000 to 4,500	3,250
2,000 to 2,500	2,250	4,500 to 5,000	3,500

Permissible Acceleration of Hoisting Speed

Finally, a table of permissible accelerations is given for various hoisting speeds which are not to be exceeded with the safety factors specified. These are shown in Table 3.

TABLE 3. PERMISSIBLE RATES OF ACCELERATION FOR CERTAIN HOISTING SPEEDS AND SAFETY FACTORS

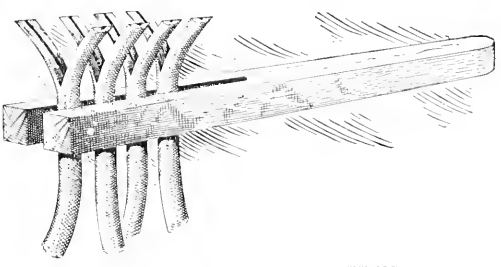
Speed, Ft. per Min.	Maximum Acceleration, Ft. per Sec.	Minimum Time of Acceleration in Which to Attain Speed Corresponding Thereto, Seconds	Speed, Ft. per Min	Maximum Acceleration, Ft. per Sec.	Minimum Time of Acceleration in Which to Attain Speed Corresponding Thereto, Seconds
500 or less	4 16	2	2,000	8 33	4
750	4 16	3	2,500	8 33	5
1,000	5 55	3	3,000	8 33	6
1,250	5 95	3½	3,500	8 33	7
1,500	6 25	4			

Device to Aid in Fuse-Spitting

By Lowe Whiting*

The device illustrated herewith is used in some of the iron mines of Michigan as an aid in blasting.

It consists of a slotted stick, 6 or 8 in. long, whittled from a piece of powder box. The ends of the fuses are



DEVICE TO AID IN FUSE SPITTING

forced into the slot, then split in the usual manner, ignited, and the stick snatched away to be used again.

It is found to be a considerable help in wet places, where the miner holds the ends of the fuses close to his body, bending over to protect them from the dropping water.

A Wire Rope "Don't"

Do not allow a wire rope to be pulled around a tree, stump or column, as such treatment tends to cause the strands to untwist and to curl up like a watch spring.—*Leschen Bulletin.*

[1]The factor of safety of all such ropes or cables when newly installed in shafts less than 3,000 ft. deep shall in no case be less than six, and shall be calculated by dividing the breaking strength of the rope, as given in the manufacturers' published tables, by the sum of the maximum load to be hoisted, plus the total weight of the rope in the shaft when fully let out.

*Manager, Whiting Engineering Co., Iron River, Mich.

Details of Milling and Smelting

Oxyacetylene Welding at Braden

By Alma Ek* and J. R. Thill*

An acetylene generator of the portable type arrived at the Braden mechanical shops in December, 1913. The machine came to Chile without any instructions as to its operation. No one then at the plant understood much about acetylene generators, and the lack of necessary instructions caused a great deal of work, worry and a few narrow escapes from serious injury. However, it was soon operated in such a way as to be a great help in the cutting of plates and structural steel. This was considered good progress, taking into account the manner in which it had been attained.

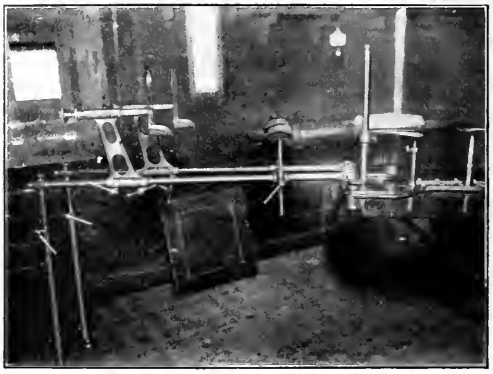
Welding was attempted under great difficulties, but was nevertheless tried because there was an enormous field for this class of work at the Braden plant. The first attempts at welding were made on blast-furnace water jackets. A number of these jackets were lying around, being perfectly good except for the last few inches near the top on the inside. Here the action of the acid in the wet concentrates charges ate away the metal until it finally gave out. To patch such a jacket in the shops with the previous equipment was costly, and at the same time a perfect job was almost impossible.

Having no one who understood the art of making a good weld, or even the proper flame to be used, it was necessary to do a lot of experimenting. The first attempts consisted of welding together two small pieces of steel plate and then breaking the weld by bending, and this naturally gave poor results. It was by this method, however, that the proper flame was discovered. After many trials a weld was made that was stronger than the original metal, being slightly heavier. An attempt was then made at welding a patch on the most worthless jacket at hand. Here the problem of expansion and contraction of metals was encountered.

The bad part of the jacket was first cut out, after which a plate was laid on top. The first three edges made a fairly successful weld, but the last seam continually cracked while cooling. After several experiments a jacket was welded successfully by first cutting away the worn portion and also including several inches of the flange and then taking a ⅜-in. boiler plate and welding first the seam across the face of the jacket. This was then heated with the torch and flanged into place, after which it was trimmed with the cutting torch and the other three seams welded. Since then all our jackets have been patched by cutting out the worn portion and flanging a plate, as shown in Fig. 1, and then welding by first doing the seam across the face of the jacket. Fig. 2 shows a number of blast-furnace jackets all welded, tested and ready for use. These have since been in service for almost one year and have stood up under such severe conditions that they may be pronounced an entire success.

*Master mechanic and assistant master mechanic, Braden Copper Co., Rancagua, Chile.

The first welding of cast iron was done under the most trying conditions. A nut fell from the safety air-discharge valve into the impellers of a No. 7 Roots rotary blower, cracking one impeller for a distance of 15 in. and the other for a distance of 9 in. This threw the faces out of line so badly that the machine was unable to run. This job was a difficult one. The impellers were first wedged so that they would come in line. They were then heated with a crude-oil torch to a dull red and welded, after which they were again thoroughly heated and allowed to cool slowly. The rough weld was then chipped and filed to a neat fit, and in 27 hr. from the time the blower was disabled it was again in first-class condition and has been running continuously ever since. Had this weld failed or been unsuccessful, the blower would have gone to the scrap heap. Since then many cast-iron welds



APPARATUS MADE FOR BRADEN HOSPITAL

This is used in connection with the X-ray machine in setting bones and dislocations of the lower extremities. It would have been very difficult to have made the apparatus in the Braden shops without the oxyacetylene flame.

have been made on hoisting-engine frames, large and small pulleys, cylinders, etc.

Figs. 3 and 4 show a broken motor frame. This motor is used on the blast-furnace charge cars. The bearing *A* was broken off completely, and *B* had two sections broken out. The most difficult part of this job was to keep the two bearings in line, owing to the position of the break, but by clamping a mandrel in the bearing *B* to hold the broken part *A* in position, little trouble was experienced.

After being successful with steel and cast-iron welding, we turned to copper, which offered many obstacles not previously encountered. The thermal conductivity of copper is high, therefore heat is much more rapidly dissipated than in either iron or steel. Copper also oxidizes rapidly. The oxide will dissolve in the molten metal, and unless the greatest care is exercised the mechanical properties will be changed materially. The molten metal will also dissolve gases from the welding flame, principally carbon monoxide and hydrogen. These gases will

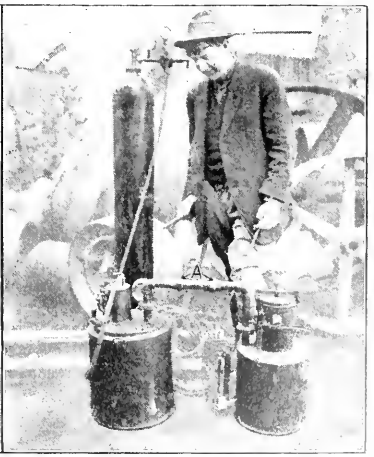

Fig. 7—Small portable outfit

OXYACETYLENE WELDING AT THE BRADEN COPPER CO.'S WORKS IN CHILE

produce blow-holes in the metal while cooling. Several attempts were made that were unsuccessful, owing mainly to blow-holes in the weld, but since obtaining a suitable flux to offset this difficulty, a number of copper cylinders used for electric heaters have been successfully welded and it is expected that all the blast-furnace water-cooled copper spouts will be repaired as they become worn.

The design and building of acetylene generators that could be more easily taken to remote parts of the Braden works were then undertaken. The result was the machine shown in Fig. 5, later the one in Fig. 6, and finally the small portable machine in Fig. 7. As they are all successful, a brief description may be interesting. The machine shown in Fig. 5 is built on the principle that the fine carbide drops from the hopper above into the water. The gas thus generated passes through a felt strainer, then through the water safety chamber, then through the reducing valve and into the service hose. The machine is not fitted with all the so-called automatic safety devices that are to be found on the high-priced portable or stationary generators. A good operator is mainly depended upon for safety, and without a good operator no machine is safe. The machine is also equipped with a good safety valve, which has never been necessary because of a feeding device developed at this works. The feeding arrangement deserves special mention. It consists of a hinged gate with the operating rod passing through the carbide to the top of the hoppers, where it is connected to the arm of the operating lever, which is so counterbalanced that the gate is closed automatically. This gives a positive feed, as the operating rod passing through the carbide acts as an agitator and prevents the carbide from arching over the opening. Trouble is experienced frequently with the more expensive slide-valve arrangement, which operates so slowly that the carbide often bridges and refuses to drop; on being loosened by shaking or jarring the machine, the carbide drops so quickly that the valve cannot be closed in time to prevent a dangerous pressure developing. The locally developed device has proved so successful that the hoppers of two factory-made machines have been changed to this arrangement.

The machine shown in Fig. 6 is the same as that in Fig. 5, with the exception of being a little larger and with all joints oxyacetylene-welded. Fig. 7 shows an acetylene generator designed especially to produce gas enough to do small jobs of cutting or welding in some place where too much time or expense would be involved in transporting a larger machine. It can be disconnected at *A* and each half carried by a man up a ladder if necessary. It can then be set on a flat place, connected and filled with the necessary water and carbide. It is not claimed that this machine is foolproof, but it is safe when used by an intelligent operator.

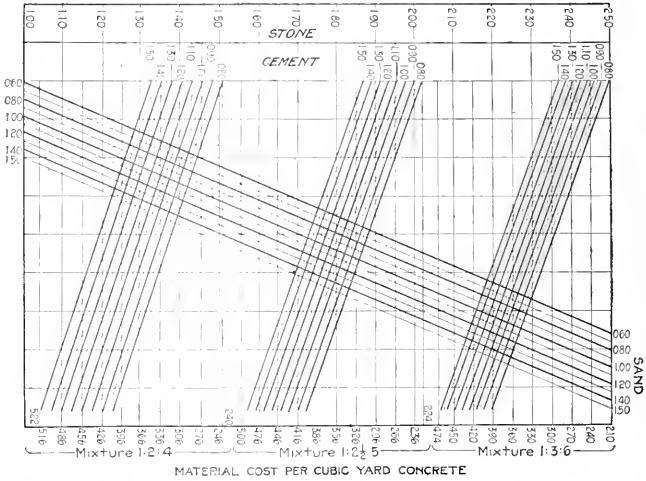
With the number of generators at hand the Braden company can now handle any piece of work that it pays to do by this method. It is found that not only can repair work be done more cheaply by this method, but also much new work, such as pipes, oil heaters, tanks and boilers. Joints can be made to stand a pressure of 100 lb. per sq.in. when required. This work is being done with a saving in both time and money.

The small engraving shows an apparatus that was made in the company shops for use in the Braden hospital, in connection with the X-ray machine, in setting bones or dislocated joints of the lower extremity of the body. It would have been a difficult piece of work for the Braden shops without the use of this process.

The Braden Copper Co. at present has three generating plants in operation—one in the machine shops, one at the smelting plant and one in the mill. There are also ready for immediate use two of the small portable generators.

Concrete Cost Computing Chart

A chart from which the cost of a cubic yard of concrete may be readily traced for different variations in mix and cost of material has been prepared by A. Pearson Hoover, contracting engineer with the John W. Ferguson Co., building contractors, Paterson, N. J., and New York City.



Begin with the cost of the stone on the left-hand scale; read along the horizontal line to the intersection with the long oblique lines representing the cost of sand; follow this proper cost line to its intersection with the inclined lines representing the cost of cement; from whence read horizontally to the right and obtain the total material cost of the concrete per cubic yard.

Cyaniding Concentrates

The application of flotation concentration brings up again the question of the cyanidation of concentrates. It is well to remember that former practice applies with the one difference of oil elimination. Roasting the concentrates is one procedure, but it has the disadvantage of leaving an objectionable carbon deposit. An alternative is in washing the concentrates with a hot alkaline solution—in other words, saponifying the oil and washing it out. The method may be of value in some cases.

Company Reports

Oriental Consolidated, Chosen

The Oriental Consolidated Mining Co., Usan District, Chosen, reports a profit of $660,095 for the year ended June 30, 1915. The mines produced 297,889 tons of ore having a gross value of $1,951,588, or $6.54 per ton. The following table gives a summary of the operating record for the year:

Receipts:	Per Ton Ore
From bullion	$3.29
From concentrates	2.16
From store profit	.04
From interest and other receipts	.12
Total	$5.61
Expenditures:	
Mining costs	$1.91
Milling costs	.48
Concentrate expense	.21
Transportation of ore	.01
General expenses	.48
Total operating and general expenses	$3.09
Development of outside mines	.07
Construction expenses	.24
Total expenses	$3.40
Surplus for year	2.21
Total to balance with receipts	$5.61

Mining costs consisted of 83.273c. per ton for supplies, 0.608c. for assays, 1.347c. for shops, stables, etc., 12.689c. for salaries and board, 78.726c. for payrolls and 14.661c. for electric light and power. The principal items of mining supplies were: Cordwood, 10.471c. per ton; mining timber, 26.498c.; lumber, 8.968c.; charcoal, 1.401c.; dynamite, 0.884c.; detonators, 1.512c.; candles, 7.573c.; fuse, 3.132c.; oils and lubricants, 0.855c.; drill steel, 1.682c.; iron, steel and rails, 2.291c.; tools and hardware, 0.909c.; miscellaneous supplies, including pipe and fittings, pump parts, etc., 7.267c.; and electrical supplies, 0.830c. per ton of ore.

The report gives the following quantities of supplies used: Cordwood, 8,042 cords; mining timber, 125,664 pcs.; dynamite, 168,040 lb.; detonators, 921,719 pcs.; candles, 172,560 lb.; fuse, 180,625 ft.; kerosene, 460 gal.; cylinder oil, 1,105 gal.; engine oil, 2,915 gal.; lubricants, 3,101 lb.; drill steel, 59,302 lb.; iron bar, 21,194 lb.; iron sheet, 14,568 lb.; steel, 784 lb.; and nails, 29,725 lb.

The principal items making up the milling cost of 48.207c. per ton treated were: Supplies, 14.907c.; assays, 0.615c.; shops, etc., 2.567c.; electric power, 16.340c.; salaries and board, 7.27c.; and payroll, 6.508c. per ton.

The following supplies were used in milling operations in the quantities stated. Cordwood, 3,239 cords; battery shoes, 586 pcs.; battery dies, 438 pcs.; bosses, 26 pcs.; tappets, 18 pcs.; cams, 12 pcs.; stems, 24 pcs.; cam shafts, 19 pcs.; crusher shoes and dies, 2 each; iron bar, 9,984 lb.; iron sheet, 12,889 lb.; steel, 3,209 lb.; candles, 1,200 lb.; kerosene, 655 gal.; cylinder oil, 140 gal.; engine oil, 770 gal.; lubricants, 1,292 lb.; quicksilver, 30,554 oz.; and nails, 3,589 lb.

The assay office ran 36,898 assays at a cost of 12.75c. per assay.

The ore reserves of the various mines operated by this company are estimated to contain 841,000 tons having a gross value of $1,841,085. The Kuk San Dong reserves were exhausted, and the property has been closed down. The company ended the year with $463,410 in cash after paying dividends aggregating $858,780. Current debts amount to $52,189. The company's store carries about $266,688 of supplies on hand.

American Smelting and Refining Co.

The American Smelting and Refining Co. reports a profit of $5,019,982 for the six months ended June 30, 1915, an increase of $53,290 over the same period in 1914. Dividends aggregating $3,004,900 were paid. The accompanying summary of income and profit and loss for the American Smelting and Refining Co. and the American Smelters Securities Co. gives a comparison for the first half of 1914 and 1915.

	Six Months Ended June 30, 1915	Six Months Ended June 30, 1914
Net earnings of smelting and refining plants and industries dependent thereon	$5,234,925.47	$5,462,094.17
Net earnings from mining properties	767,469.09	614,727.19
Total net earnings of operating properties	$6,002,394.56	$6,076,821.36
Other Income—Net: Interest, rents, dividends, commissions	754,958.68	705,432.78
Gross income	$6,757,353.24	$6,782,254.14
Charges Against Gross Income:		
Administration expenses	$449,105.75	$470,924.96
Research and examination expenses	23,492.23	30,390.31
Corporate taxes, including accrued income tax	71,480.03	74,378.83
Interest on debenture bonds	388,680.61	450,000.00
Amortization of discount on bonds	25,000.00	25,000.00
Depreciation	779,612.60	764,918.13
Total charges	$1,737,371.22	$1,815,562.23
Net income for six months	$5,019,982.02	$4,966,691.91

The company purchased and improved a zinc plant situated at Sand Springs, Okla. The total expenditures for property, additions, new construction and improvements was $860,212, of which $779,612 was charged off as depreciation. Cash on hand and in transit increased $11,114,600 during the period. Better conditions in Mexico are expected to help the company's showing in the near future.

The American Agricultural Chemical Co., New York, reports a net profit of $3,675,145 for the year ended June 30, 1915. Dividends amounting to $1,654,176 were paid on the preferred stock and $737,236 on the common stock. The profit stated was after charging off $890,393 for depreciation of plants and mines and $821,488 for freight, losses and contingencies. The report shows a total profit of $34,576,102 since the organization of the company, of which $24,799,401 has been paid out in dividends. Current assets total $35,359,732, of which $15,444,628 represents accounts and $8,795,492 bills receivable. Cash on hand aggregates $2,109,559. Current liabilities total $6,541,837, which includes $4,835,080 of notes payable. There are $9,428,000 of first mortgage 5% bonds and $7,500,000 of debenture 5% bonds outstanding. The sum of $157,408 was deducted from the year's profit to cover bad debts.

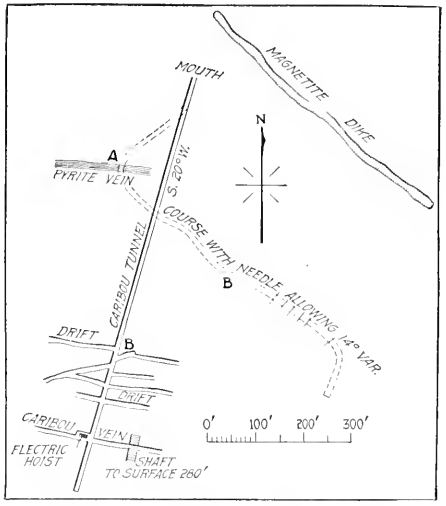
Correspondence and Discussion

Peculiar Magnetic Phenomenon

I wonder if any of the "Wise Men of the East" can explain the following uncanny magnetic freak. It has annoyed me much in not being able to solve it myself.

Last winter I had occasion to examine the old Caribou mine in Boulder County, Colorado, once a famous rich silver mine and now being opened up again by Henry P. Lowe. My attention was called by Norton H. Brown, superintendent of the mine, to certain magnetic disturbances. I hardly knew whether to take him seriously until I had verified every statement he made. The facts are as follows and were determined by me with a Brunton compass.

First: The Caribou crosscut tunnel is 900 ft. long, true course S20W. It cuts six veins all within a space of 200 ft., on which drifts are driven. Allowing the proper Colorado variation of 11° E and taking bearings



MAGNETIC COURSE IN CARIBOU TUNNEL

every 50 ft. in the tunnel gives the remarkably crooked course shown on the map by dotted lines, the two ends of the tunnel registering the right course, but all out of joint in between.

Second: At any of the drift and tunnel intersections, the needle reading of the tunnel is about S50°E, as per sketch, but if one goes 10 ft. or so into any of the 10 drifts, the needle reads all right, and one would think the "Tommyknockers" had possession of the mine when, holding a compass in one's hand in the tunnel, with the needle pulled around 70° from its proper course, one can back off into any of the drifts and watch the needle gradually swing around 70° to its proper North-Pole habits.

Third: Walking over the tunnel line on the surface, which rises 20°, and taking needle readings every 50 ft., as in tunnel, shows no such freakiness, but a uniform needle disturbance of 10° or S10°W in place of S20°W. The only observable geological condition that might affect the needle is the existence of a strong magnetite dike 10 ft. wide, standing vertical and running S50°E, which, strange to say, is identical with the tunnel readings for 600 ft. of its length and may give a clue to the mystery. At *A*, where tunnel readings change 90° from NE to SE, there is nothing but a small iron-pyrite vein crossing at right angles. It has no magnetic qualities, but I have thought possibly to one side of the tunnel it might change to magnetite and account for the unusual disturbance at that point.

One would naturally attribute the whole matter to the magnetite dike, but why does the needle read true at the mouth and face of the tunnel, which are two points the nearest and most remote from the dike? Also what influence can account for the needle reading O.K. only 10 ft. away from tunnel in any of the drifts? Why does a set of readings over the tunnel line at surface not agree with those taken in tunnel? Can the bore of the tunnel itself be magnetic? If so, why does it not act uniformly and who ever before heard of a tunnel hole acting as a magnet? Insulated wires of 250 voltage extend from *B* to the hoist, and I was working up a theory along that line until Mr. Brown told me the same conditions prevailed before the power line was installed. The rock formation is granite and schist.

If I had not observed this myself, I should be inclined to question if the author had not been out to a banquet the night before. The tunnel, however, is still there to back me up, and the Brunton compass will ordinarily do fine work, but it is sure locoed in Caribou tunnel.

Denver, Colo., Dec. 2, 1915. EDWIN E. CHASE.

NEW PATENTS

United States patent specifications listed below may be obtained from "The Engineering and Mining Journal" at 25c. each. British patents are supplied at 40c .each.

AIR-HOSE COUPLING. William Engle, Taylor, Wash. (U. S. No. 1,161,641; Nov. 23, 1915.)

ALKALI HYDROXIDES—Process for the Simultaneous Production of Soluble Alkali Hydroxides and Cement-Making Material. Arthur William Heyman, Northampton Borough, Penn. (U. S. Nos. 1,160,171 and 1,160,172; Nov. 16. 1915.)

ALUMINA—Crystalline Fused Alumina and Method of Making the Same. Leonard B. Coulter, Niagara Falls, N. Y., assignor to The Carborundum Co., Niagara Falls, N. Y. (U. S. No. 1,161,620; Nov. 23, 1915.)

ALUMINUM—Process for Producing Aluminum from Clay, Kaolin, and Other Aluminum Silicates. Grenville Mellen, East Orange, N. J., assignor of one-half to United Aluminum Ingot Co. (U. S. No. 1,160,431; Nov. 16, 1915.)

ALUMINUM—Process of Melting Aluminum or Aluminum Alloys. Grenville Mellen, Mount Vernon, N. Y. (U. S. No. 1,-160,130; Nov. 16, 1915.)

ALUMINUM—Solder. Joseph Cayocca, Sacramento, Calif. (U. S. No. 1,161,612; Nov. 23, 1915.)

AMALGAMATING MILL—Abrasive Amalgamating Mill. James B. Shackey, San Francisco, Calif. (U. S. No. 1,161,418; Nov. 23, 1915.)

The Juneau Gold Lode

F. W. Bradley, president of the Alaska-Juneau Gold Mining Co., in the application for the listing of the shares of that company on the New York Stock Exchange, gave the following succinct description of the Juneau gold lode:

The vein consists of slate carrying gold-bearing quartz irregularly distributed through it in the form of veinlets, stringers and masses. Dikes of metagabbro have intruded themselves into the vein, and these dikes in turn carry quartz similarly distributed. In some places the quartz is sparingly distributed, while in others it is more or less concentrated. It seems highly probable that this quartz can, to a considerable degree, be sorted from the inclosing vein matter, thus yielding a materially higher mill feed than the average of the mass.

From 1896 to 1914 a 30-stamp mill was operated upon the Alaska-Juneau property with the result that 295,807 tons of ore were milled, yielding $669,589.31, or at the rate of $2.26 free gold per ton. This yield was obtained by milling about 63% and rejecting about 37% of the ore mined. If the whole 472,783 tons had been milled, the free-gold recovery would have been about $1.50 per ton, as the rejected vein matter is also gold-bearing. No attempt was made to save the values in the sulphides which, if saved, would have added about 20c. per ton. A tailing loss of an equal amount is definitely known, so that the total value per ton would approximate $2. All of the ore was from selected surface workings scattered over the best known portions of the vein.

The main working tunnel, known as the Gold Creek tunnel, at an elevation of 425 ft. above sea level, has been driven since the aforementioned surface mining and milling work, and at a point 6,450 ft. from the portal an incline raise has been put through to the surface. In driving the Gold Creek tunnel, a portion of the vein on the west side of what is known as the Silver Bow fault was crosscut diagonally for a distance of 650 ft., disclosing bodies of ore the assay values of which average slightly less than $2 per ton. The ore extracted from both the Gold Creek tunnel and the intermediate level opened from the incline raise at an elevation of 495 ft. above the Gold Creek tunnel has been milled in the new mill erected on Gastineau Channel. Because of the mixture of waste with the ore, due to opening up these two levels preparatory to stoping, the mill-feed assay value of 50,000 tons milled up to Dec. 1, 1914, averaged $1.36 per ton.

The cubic contents of the vein above the Gold Creek tunnel level and between the eastern and western ends of the Alaska-Juneau property, totals approximately 500,000,000 tons of slate, metagabbro and quartz. From this there should be mined, from selected places, 80,000,000 to 100,000,000 tons of vein matter and quartz suitable for milling that should yield a net profit of from 70c. to $1 per ton, depending upon conditions of mining that cannot at this time be estimated within closer limits of ultimate profit. Areas will probably be found in which mining may profitably be conducted by sorting, leaving two tons in the stopes for every ton milled. Other areas will probably be found, all of which may be mined without the necessity of mine sorting, but on this there is nothing definite known.

The mining chances below the Gold Creek tunnel level promise an addition of twice as much tonnage of the same value as it is believed the vein will yield above the tunnel. These mining chances are based upon the fact that in a parallel vein two miles away, on Douglas Island, the orebodies are now being mined at a depth of 2,900 ft. below sea level. At that depth the Douglas Island orebodies still hold their size and average values.

First Steel Billets Made in Lake Superior District

DULUTH CORRESPONDENCE

On Wednesday, Nov. 24, the fires were lighted under one of the 500-ton blast furnaces of the Minnesota Steel Co., at Duluth, and the following day, Thanksgiving, the first steel billets ever manufactured in the Lake Superior district, where iron ore has been mined for about 65 years, were turned out. The other blast furnace will be ready to go into blast within a few days. Seven of the 10 open-hearth furnaces have been finished, and several of them are now in use. It will not be many weeks before all of the 10 will be ready.

There was quite a gathering of officials of the company and prominent men of the district in attendance when the first steel was turned out. The starting of this big plant marks an important epoch for the region where iron ore has been king for so many years and where steel has never been manufactured before. There are a number of blast furnaces manufacturing charcoal pig iron, but this is the first time that high furnaces, utilizing coke for fuel, have been tried. The steel billets will be shipped East to the United States Steel Corporation, the parent company. The rail mill and other mills will not be ready for some time, probably next spring, when another great step will have been taken in the steel business in the Northwest.

Most of the iron ore that has been delivered at the plant has come from the underground mines of the Oliver Iron Mining Co. in the Chisholm district, and steady shipments are now being made. The storage yards for fuel, limestone and ore are extensive, but it will not be necessary to load up in the fall with ore, as must be done in the East, as there is plenty of the raw material close by that can be hauled to the works at any time.

When fully completed, the Duluth plant will represent an expenditure of about $25,000,000. Employment will be given to a large force of men, and Duluth will be greatly benefited by having such a plant at its door.

Australian Gold Production

The gold production of the several states of the Australian Commonwealth for the eight months ended Aug. 31 is reported as follows, in fine ounces, South Australia being estimated:

	1914	1915	Changes	
Western Australia	$13,221	$04,256	D.	$ 965
Victoria	285,069	215,763	D	69,306
Queensland	157,289	171,467	I.	14,187
New South Wales	92,852	99,833	I.	7,981
Tasmania	17,500	11,360	D.	6,140
South Australia	4,000	4,000		.....
Total	1,359,922	1,297,679	D	62,243
Total value	$28,109,588	$26,823,025	D	$1,286,563

The small increases in Queensland and New South Wales were not sufficient to counterbalance the losses in the other states. Victoria showed the largest decrease.

while that in Western Australia was comparatively small. The general result shows a decrease of 4.6% in production and points to an approximate total of $40,000,000 as the contribution of Australia to the gold supply of the world in 1915. New Zealand has not made public the usual monthly statements of production this year. So far as can be estimated, it will show a decrease at a rate equal to, if not a little greater than, that of the Australian Commonwealth.

Willow Creek Gold District*

The Willow Creek gold district lies in south central Alaska, 10 mi. north of the head of Knik Arm, the farthest inland projection of Cook Inlet and the northernmost extension of Pacific Ocean waters in Alaska. This district is an area of rather indefinite boundary, lying in the southwestern part of the Talkeetna Mountains, and has gradually come to include not only the basin of Willow Creek, but all the mountainous portion of the little Susitna River basin.

The district lies along the contact zone of a great series of granodiorite intrusives that form much of the Talkeetna Mountains. As has been repeatedly pointed out, a large part of the gold deposits of Alaska occur in such contact zones. This is the condition in southeastern Alaska and in the Fairbanks, Chandlar, Iditarod and other inland districts. The geology of the Willow Creek district is therefore favorable to the occurrence of gold deposits. Were it not for the intense glaciation of this field, it would probably yield rich placers. As it is, the preglacial gravels that are most likely to contain the gold of placers have been swept away by glacial ice. The placers now found are chiefly post-glacial concentration, which are not likely to be so rich as the older gravels. In the absence of such rich placers and under the primitive conditions of transportation that existed until recently, there has been little to attract the prospector, and hence the region has not been so carefully examined for mineral deposits as its geological features would justify.

Though the Willow Creek district is the only part of the Talkeetna region in which commercial gold deposits have been found, other positive evidence of mineralization has not been lacking. Thus many of the northern tributaries of Matanuska River that cross the granodiorite contact carry some gold in their gravels, and the same is true of some of the eastern tributaries of the Susitna. All this evidence, together with what is known of the bedrock geology, makes it probable that other gold-bearing districts will be found in this province. In any event, the region in which the granodiorite intrusives occur is well worth prospecting.

The veins of the Willow Creek district occur in well-defined fissures, and there is no reason why they should not extend to considerable depth. Surface alteration is limited to a few feet, so that the present shallow workings can be regarded as evidence of the character of ore that deeper mining may reveal. The outlook for a permanent district is therefore hopeful.

Mining costs are now high, owing to the isolation of the district and the high price of fuel. The district, however, lies close to the line of the government railroad from Seward to Fairbanks, on which construction has now begun. Moreover, this railroad is also projected into the Matanuska coal field. When this project is completed, the district will be assured of an adequate transportation service and fuel at reasonable cost. Under these conditions, larger mining operations will undoubtedly be undertaken.

*From Bulletin 607, "The Willow Creek District, Alaska," by the United States Geological Survey, 1915.

Searles Lake Potash in 1916

At the recent annual meeting of the Consolidated Gold Fields of South Africa in London, Lord Harris in reviewing the company's American investments said:

Of course the interesting question there is, What is the American Trona Corporation going to do? We experimented first of all with a process which proved after a fair trial to be unsuccessful, or, rather, too expensive and wasteful for adoption, and we have now reason to believe that the process which has been substituted will be entirely successful, besides being more economical. It is not a difficult process and has only to be adapted to the special climatic conditions of the country. A very elaborate trial of the brine was carried out during the summer by an independent firm of chemists, and the results have been reported on by capable referees so encouragingly that the company felt justified in ordering the plant, which, I am happy to say, is of a standard type, and at present it is anticipated that potash will be produced next year—the most optimistic hope in the earlier months—when we shall most probably still have the advantage of the high price obtainable for potash at the present moment. All the work necessary to secure the company's title to the area located in accordance with the mining laws of California is being carried out, with a view to obtaining an indefeasible title from the United States authorities. These proceedings necessarily take time, but our legal advisers inform us that they have no doubt that such title will be granted us in due course.

The process developed by Charles P. Grimwood has been adopted for the recovery of the salts from the Searles Lake brine. For reasons of economy of operation and better shipping facilities for the refined products, it has been decided to produce at Trona (Searles Lake) only mixed salts from the first part of the process and to refine these mixed salts at the port of San Pedro, Calif., where a site has been leased from the Southern Pacific Co. Construction is now under way both at Trona and at San Pedro. The initial units are expected to produce daily 100 tons of potash and 30 tons of borax. No other salts will be produced at first. Pending the completion of the refinery at San Pedro, a crude potash-borax salt may be marketed.

Humphreys & Miller, employed in connection with the adoption of the Grimwood process, state that there should be a recovery of at least 85% of the potash and 60% of the borax. Production costs at tidewater are estimated at $19 per ton for the first few months, at $12.87 per ton when the triple-effect evaporators are working and at $8 per ton with an enlarged plant. With a freight charge to the Atlantic seaboard (via the Panama Canal) of $7.78 per ton, this would make a cost of approximately $20 per ton with the first plant and $16 per ton for an enlarged plant having a daily capacity of 400 tons of potash and 120 tons of borax.

The Trona Ry. has been in operation since October, 1914, and early in 1915 the construction of a pumping plant and 10-in. brine pipe line from the center of Searles Lake to the site of the Trona plant was begun. Additional supplies of fresh water, for the village of Trona and the operation of the plant, have been obtained from the mountains north of Trona and right-of-way secured from the Government for pipe lines over lands withdrawn from entry.

Editorials

Blast-Furnace Capacity

The estimated production of pig iron in the United States in the month of October was 3,159,500 long tons, the largest quantity ever reported in a single month. The number of furnaces in blast indicates that the November make of iron will be quite as large as the October. The production at present is at the rate of nearly 38,000,000 tons a year, or 7,000,000 tons more than was made in 1913, the year of greatest output. That is, the blast furnaces of the country are running rather close to what is practically their maximum capacity. The statistics of the American Iron and Steel Association show that at the opening of the present year there were 451 blast furnaces, with a total yearly capacity of 44,405,000 tons. To this must be added five furnaces, then under construction but now completed, which raise the total number to 456, with a capacity to make 45,265,000 tons a year. At the present time, therefore, there is about 85% of the blast-furnace capacity active, and it is hardly to be expected that this proportion can be exceeded.

It must be remembered that a blast furnace cannot run forever without repairs; and at least 10% of the existing stacks must be out of blast at a time for relining and rebuilding, no matter how great the demand for iron may be. The list of existing furnaces has been rather strictly revised in the last two or three years, and a number of old stacks have been abandoned and dismantled. There still remain some that, on account of antiquated construction and equipment or unsuitable location, cannot work at a profit unless the demand is great and prices high. If we take these into account, 85% of the rated capacity comes very near to full employment. Moreover, a furnace will not run up to its full rating every day in the year, and its production will not be 365 times the daily rated capacity, even if under favorable conditions it may be speeded up to an excess for a few days. With a nominal yearly capacity of 45,000,000 tons, a yearly production of something under 40,000,000 is the greatest that can be attained.

The year 1915, however, will not approach that total. Early in the year demand was at a low ebb, and the officially reported make for the first half of the year was only 12,233,791 tons. Since June the production has been gradually climbing until it has reached its present high point. The first rush came in the make of the steel companies' stacks, and almost up to the present time we have heard complaints from the merchant furnaces. These have gradually disappeared, however, as more and more have gone into blast and steel interests have been obliged to go into the market for pig iron to supplement the make of their own furnaces. The first demand in the market, and the strongest at the present time, is for steel in various finished forms, though foundry work is gradually catching up with the rush.

We hear from all quarters just now, as in most boom periods, of additions and improvements at various steel works to enable them to keep up with the demand. Much work of this kind is under way or projected. Not much is heard, however, of new furnaces or of increasing pig-iron capacity. Iron men apparently believe that the present blast furnaces will be able to furnish all the iron that may be needed in the next year or two and are not yet ready to undertake additional construction of blast furnaces. It must be remembered also that the building of a new blast furnace on modern lines is a slow and expensive work, much more so than an addition to a steel plant, necessary as the blast furnace may be.

The Alaska Gold Mines

The slump in the shares of the Alaska Gold Mines Co., which, through the Alaska-Gastineau Mining Co., operates the Perseverance mine, near Juneau, Alaska, has excited a good deal of apprehension among the stockholders, who are widely scattered throughout New England and the eastern part of this country, the Alaska Gold Mines Co. being the latest promotion of Hayden, Stone & Co. The previous promotions of that house—Nevada Consolidated, Utah Copper Co., Ray, Chino and Butte & Superior—have been phenomenally successful, without exception. The Alaska Gold Mines Co. is just entering upon the first stage of its fruition.

This company owns a portion of a great lode of gold-bearing ore known to be of low grade, but believed to be capable of yielding an enormous profit in the aggregate when exploited by modern methods on a huge scale. The company reckoned on obtaining a net yield of $1.50 per ton at a cost of 75c. per ton. In the last annual report of the company, D. C. Jackling, the managing director, estimated a minimum of fully developed, partially developed and probable ore at not less than 75,000,000 to 100,000,000 tons having a recoverable value of $1.50 per ton, and the ultimate production of this grade of ore from the entire property will unquestionably be far in excess of these figures." Four mill units designed to treat 6,000 tons per day were planned for the initial equipment, the ultimate that was in view being 30,000 tons per day, but the first four units, which are now nearly completed (and have been partly in operation for several months) have been found to be capable of treating 10,000 tons per day instead of 6,000, and it is thought that their capacity may be raised to 12,000.

Previous to the putting of this mill into operation, the greatest skepticism among engineers pertained to the claims of Mr. Jackling and his associates that they were going to be able to mine and mill gold ore in any way for so small a sum as 75c. per ton. Nothing like that had ever been attained in the Treadwell group of mines opened on a parallel lode on the other side of the Gastineau Channel. Mr. Bradley and his associates operating the Treadwell group were among the skeptics, but they became converted and undertook the development of the Alaska-Juneau property, which adjoined the Perseverance. Mr. Jackling has already showed that he can mine and mill for about 60c. per ton, beating his orig-

inal estimate by a handsome margin and thereby earning a new triumph for himself.

The recent slump in the shares of the Alaska Gold Mines Co. began with rumors that the ore was not turning out so high in grade as was expected. Mr. Jackling in an interview stated that an unexpected occurrence of low-grade "schist" (slate) had been encountered in a part of the mine from which it was hoped to draw a higher grade of ore, and this material having to be put through the mill had reduced the general average. Up to the end of October the new mill had treated about 900,000 tons of ore, assaying about $1.25 per ton instead of the $1.35 expected. The cost of mining and milling, however, had been 15c. a ton lower and the loss in tailings about 5c. a ton lower than estimated, wherefore the net return was only 30c. per ton below the estimate for the average ore.

The Juneau gold lode consists of slate carrying gold-bearing quartz irregularly distributed through it in the form of veinlets, stringers and masses. Dikes of metagabbro have intruded themselves into the lode, which dikes in turn carry quartz similarly distributed. In some places the quartz is sparingly distributed, while in others it is more or less concentrated. The nature of the occurrence of the gold-bearing quartz in this lode implies irregularities in returns, portion by portion or month by month. These irregularities have always been recognized by the managements of both the companies developing the great lode. When the lode is so opened that ore can be drawn from a great many places, which is not yet the case, such irregularities will tend to be equalized in a true general average. It is premature to jump at the conclusion that the Juneau ore is not going to yield so much per ton as was expected.

As to the value of the shares of the Alaska Gold Mines Co., opinions will continue to differ until it has been demonstrated by the milling of millions of tons of ore just about what the average yield and average cost are going to be, after which these shares, being based upon gold, which is not so much subject to market vicissitudes as copper, zinc, etc., will probably become as steady as such well-seasoned gold-mining shares as Alaska-Treadwell, Homestake and others of that class. In figuring an amortized value it is necessary to take into consideration the life of the mine. A mine with a delimited ore-body figured upon as lasting 20 years ought to pay about 9½% gross in order to afford 6% net. As the expected life rises above 20 years the necessary annual amortization diminishes rapidly. When it is a matter of 50 years' life, a gross of less than 6½% is needed to yield 6% net, which is about the basis on which our great mines sell, whether they ought to or not.

The elements for a close valuation of Alaska Gold Mines shares are not yet available. If the company possesses 100,000,000 tons of ore yielding 75c. per ton, there is $75,000,000 net to be had; if only 40c. per ton, $40,000,000. If the extraction be at the rate of 3,000,000 tons per annum, there would be 33⅓ years' life; if at the rate of 6,000,000 tons per annum, only half as much. In general, the more rapidly the ore is extracted from a mine the more profit there is, and this is especially true of a gold mine. In the case of the Perseverance mine its owners expect to get a good deal more than 100,000,000 tons of ore.

The Advance in Silver

The price of silver has been remarkably even since the drop of about 3d. per ounce in the London market, which followed the outbreak of war last year. From October, 1914, up to October of the present year the variation in the monthly averages has not exceeded 1d. per ounce. The demand for silver from the East has been lighter than usual throughout this year, the shipments to India—usually a ruling factor in the market—having been less than in 1914 by 25%, while China has not only taken practically nothing from Europe, but for part of the time has sold rather freely from its own stock. On the other hand, there has not been an excessive supply, and sellers have not pressed the metal for sale, accommodating themselves to the conditions of the market. Silver production in the United States has been about the same as last year and in Canada, rather less; while in Mexico there has been a considerable decrease. The market has also been from time to time supported by buying for the United States Mint.

Since the close of October, however, there has been a steady advance, and the price, which stood at about 24d. in London on Nov. 1, has advanced to 26¼d., showing the greatest variation since the drop at the beginning of the war. This advance seems to be firmly held, and there are indications that it may go still farther.

As usual, several causes seem to be contributing to the rise. The demand from India has been better, and there is reason to believe that Chinese stocks are low and that there will be little selling from that country for a time, and perhaps some buying. The most direct cause is found in large purchases for the British, French and Russian mints. War conditions have brought about an unusual demand for silver coins, and the mints of the several countries are busy supplying them. It seems probable that the coinage demand will continue for some time. An increase in the Indian shipments is also confidently looked for.

Direct shipments to the East from this country have shown a considerable increase this year, the total exports from San Francisco to the end of October having been 11,250,000 oz., or about 1,200,000 oz. more than last year. The total this year was about one-sixth of the exports from London, but this is a larger proportion than usual and may indicate a growing disposition to take from San Francisco rather than London. The supremacy of London in the silver market, however, is so firmly rooted in the conservative East that it will be difficult to bring about a change.

The demand for silver coinage produced by the war is something that has heretofore been overlooked, attention having been concentrated on the huge demands for steel, copper, zinc, lead, etc., but nevertheless it has been real. The millions of men in the field are probably not rich in spending money, but they have some, which in the aggregate is considerable, and they live under conditions that result in the utter loss of a good deal of it. The recent requirements for silver appear to be, partly at least, to replace such loss. Whatever be the causes for it, the rise in the price for silver is a very satisfactory event for the producers at Cobalt, who have been carrying large stocks in their vaults for a long time, while more activity in prospecting is reported from there than for years past.

BY THE WAY

According to the *Peking Daily News*, Hunan Province is full of minerals, among which are antimony deposits in the central portion, pewter deposits in the southern, and copper, lead and coal in the southwestern. Since the Kiang Wha pewter mine is later mentioned specifically, we judge that the makers of fake antiques had better get hold of this mine and turn out pewter plates while you wait.

⁂

The following excerpt from a letter by a late resident of Morenci, now of Duncan, Ariz., needs no comment: "I have been driven from my home by the strikers. The sheriff and governor are hand in hand with them, and not only refuse to protect anyone in sympathy with the company, but go so far as to tell such people to get out of town. It is the worst state of affairs in this country when American citizens paying taxes for protection to their lives and property are not even allowed to live peacefully in their own homes."

⁂

A correspondent in Clifton, Ariz., sends us the following under date of Nov. 26: "The strikers are prepared to hold out indefinitely. The American Federation of Labor has passed resolutions indorsing the strike, and the Miami miners' union will continue to solicit its pay-daily subscription. Several women's organizations have the subject on the anvil, and the Globe and Miami teams will play a game of football for the strikers' benefit. Since the failure of the Greenlee supervisors to authorize 300 additional deputies and in the absence of any other payroll, the business of seeing that the company doesn't blow up its own property, etc., is so rotated among the union boys as to do the greatest good to the greatest number. One serves as deputy a while and then another. W. J. Donahue, of the Duncan tent colony, head supply man for the Detroit company, spent Saturday night, Nov. 20, in Morenci and was fired on through window of his own home. The bullet sunk harmlessly in the wall, however, and Donahue fired back. It is the consensus of opinion that Donahue and an accomplice was merely taking a friendly shot at each other. Summing up the strike situation, the score is 0 and 0, union at the bat, Davies and Myers umpiring. It is thought that directly after the federal investigation is concluded, most of the shift bosses, superintendents and managers will be spent to the penitentiary."

⁂

The scenes of the McCune-Marañon River Placers controversy have been shifted to Peru. Mr. McCune, who formerly controlled the property and later was made general manager, arrived in Peru about a month ago and in an interview in the *West Coast Leader* gives a different version of the fraud proceedings instituted in Wilmington, Del., last summer. Mr. McCune claims to have notified the directors on Feb. 8, 1915, of the failure to find bedrock and advised the abandonment of the enterprise; the directors, desiring to shift the responsibility for the fiasco upon someone else, decided to make him the "goat." Instead of an average of 80.9c. per cu.yd. and the belief that the bedrock gravel would run from $4 to $5 in gold per yd., as stated in the prospectus, subsequent drilling showed a layer of low-grade or worthless "gravel for about 20 ft. and an understratum of mud which at 100 ft. in depth showed no indication of bedrock, where it was originally believed the bonanza deposits would be found." Preceding Mr. McCune's arrival in Peru, George P. P. Bonnell, former treasurer and secretary of the company, landed at Callao in company "with an engineer by the name of Lohman and a United States postal inspector by the name of Barber." They left for the Marañon and, it is supposed, are searching for evidence. The *Leader* adds that "Mr. McCune, who has come to Peru to look after his interests in the case, is also accompanied by an engineer, and leaves for the *sierra* on Friday."

⁂

November Mining Dividends

Dividends disbursed in November, 1915, by 27 United States mining companies making public reports amount to $6,032,264, as compared with $1,137,123 in November, 1914. Industrial and holding companies allied to mining paid $11,196,293, as compared with $8,692,022 a year ago. Canadian and Mexican companies paid $1,057,607, as compared with $634,894 in November, 1914. The report of the Anaconda dividend in the *Journal* of Nov. 6, as being in October, was an error. The stock merely went ex-dividend at that time, while payment was made in November.

The totals for the first 11 months of the year are as follows: Mining companies, $61,012,688, as against $50,-

United States Mining Companies	Situation	Per Share	Total
Ahmeek, c	Mich	$2 50	$125,000
Alaska Mexican, g	Alas.	10	18,000
Alaska Treadwell, g	Alas.	50	100,000
Alaska United, g	Alas.	30	54,060
Anaconda, c	Mont.	1 00	2,331,250
Bunker Hill Con., g	Calif.	02½	5,000
Bunker Hill & Sullivan, l s	Idaho	25	81,750
Camp Bird, g	Colo.	24	267,312
Chief Con., s g l	Utah	.05	43,838
Champion, c	Mich.	2 00	200,000
Golden Cycle, g	Colo.	02	30,000
Gobi King, g	Colo.	.01	10,000

* Stock dividend

$15,223 in 1914; metallurgical and holding companies, $76,638,095, as against $78,819,124 in 1914; Canadian and Mexican mines, $8,499,315, as against $14,315,259 last year.

Hecla, which appears in the accompanying detailed table of disbursements, paid its one hundred and fiftieth dividend:

PERSONALS

C. W. Purington has returned to London from Irkutsk, Siberia.

Walter McGrath has returned to Petrograd from Central Siberia.

Thomas A. Varden is at Sault Ste. Marie, Mich., on examination work.

Sydney H. Ball has returned from a several weeks' trip to British Columbia.

H. M. Payne has returned to London from Bodaibo in the Lena Region, Siberia.

Ross Browne Hoffmann has returned to Petrograd from Tomsk; he will soon return to Siberia.

R. Gilman Brown, Deane P. Mitchell and J. P. E. Webster have just returned to London from Russia.

A. F. Gernet has returned from a visit to the Kedabeg copper mines in the Caucasus, of which he is managing director.

Diamondfield Jack Davis, and Henry Webber, both formerly prominent in Goldfield, are now operating in Oatman, Arizona.

Edmund Putnam of Parral, Mexico, and Boston, is in New York in connection with a kaolin mine near Rome, Ga., in which he is interested.

A. H. Buck is making a study of the geology of the Johnson district for the Black Prince Copper Co., and will be in Denver about Dec. 20 next.

R. H. Shields, of Houghton, Mich., president of the New Baltic and New Arcadian Copper companies has gone to Boston and New York on business.

J. P. Hutchins has returned to Petrograd after visiting the Altai region in Siberia and examining the manganese deposits of Chiaturi in the Caucasus.

Walter Straehe returned to New York on Nov. 28 from Greenland where for the last six months he has been examining mineral properties on the west coast.

Manager Bart L. Thane, of the Alaska Gold Mines Co., left Juneau for San Francisco late in November to work on a mining deal that arouses much curiosity in Juneau.

J. A. Replogle, Arthur E. Newbold and Herbert F. Black have been chosen directors of the Cambria Steel Co. in place of Theodore N. Ely, Samuel T. Modine and Childs Frick, resigned.

Benjamin Magnus, formerly general manager of the Mt. Morgan Gold Mining Co. in Australia is now practising as consulting engineer. His address is care General Development Co., 61 Broadway, New York.

Professor J. H. Bragg, of University College, London, has been awarded the Nobel Prize for Physics for 1915 by the Swedish Royal Academy of Science for an examination by X-rays of the formation of crystals.

Pierre Bouery, for 15 years manager of La Grange hydraulic mine at Weaverville, Calif., has been appointed manager of the Valdez Creek Placer Mines in Alaska. Under Mr. Bouery's charge La Grange has been considered one of the most successful hydraulic operations in the world.

Word has been received from Eugene Schwaderer, one of the Michigan College of Mines students who left Houghton for South Africa in July, that the party has arrived at Messina in the Transvaal and found 20 Americans working there for the company, mostly men from Butte or Michigan.

Dr. John A. Mathews, who has been for a number of years general manager of the Halcomb Steel Co., Syracuse, N. Y., has been elected president of the company, succeeding H. S. Wilkinson, resigned. He also succeeds Mr. Wilkinson as president of the Syracuse Crucible Steel Co., a connected company.

Frank S. Badger, of J. G. White & Co., Ltd., sailed on Dec. 1 for Colombia where he will make a power reconnaissance for the Anglo-Colombian Development Co. which has under contemplation the construction of additional dredges in the Condoto gold-platinum region back from Buenaventura on the west coast.

Dr. L. D. Ricketts, of Bisbee, on account of his work in promoting the mining industry of Arizona was selected by Governor Hunt to visit the San Francisco exposition and receive an official greeting as the state's most distinguished citizen. On Nov. 17 he was the guest of the exposition directors at a luncheon in the California Building, where speeches were made by a number of mining engineers and a commemorative bronze medal was presented to Dr. Ricketts.

OBITUARY

Zachary Merton, head of Henry R. Merton & Co., London, died Nov. 30, according to a cable despatch just received.

Philip N. Shannon died suddenly in Pittsburgh, Penn., Nov. 22, aged 72 years. He was for many years a prominent oil operator being a pioneer in Pennsylvania and also holding large interests in Texas, Wyoming and Alabama.

W. J. Guthrie, formerly of Butte, Mont., died at his home near Los Angeles, Calif., Nov. 20. An autopsy is reported to have disclosed the presence of cyanide. It was stated that no physician was in attendance at the time of his death and there was some delay in notifying authorities of the death.

Orville A. Derby committed suicide in Rio de Janeiro, Brazil, Nov. 27, according to a cablegram from that city. The reason for his act is not known. Mr. Derby had served the Brazilian Government for many years as a geologist, and had been chief of the survey since 1907. He first went to South America in 1875 from Cornell University, where he had been an instructor in geology for two years following his graduation there. He was a frequent contributor on geological subjects to scientific journals. Mr. Derby was born at Kelloggsville, N. Y., in 1851. He was unmarried.

Byron Noel White died at Spokane, Wash., Sept. 11, aged 65 years. Born in St. Thomas, Ont., he worked as a young man in the Michigan copper country as a miner and prospector for a number of years, going thence to Spokane about 30 years ago. There he engaged in mining, with which he continued to be connected. He was one of the original owners of the Slocan Star mine, in British Columbia, and at the time of his death he was still largely interested in that property. He was also interested in the Pueblo mine, in Whitehorse copper camp, southern Yukon Territory, and, as well, in mining properties in Oregon. Besides, he operated in Mexico for a time. Mr. White's chief mining activities for a number of years were in connection with the development and productive operation of the Slocan Star mine, situated near Sandon, British Columbia. To acquire the Slocan Star group, which eventually comprised about a dozen mineral claims, in 1892 the Byron N. White Co. was incorporated with Byron N. White, president and general manager. Protracted and costly litigation between the Star Mining and Milling Co. as plaintiffs, and the Byron N. White Co. as defendants, during a period of about 10 years, was finally determined by a judgment of the Supreme Court of Canada, leave to appeal from which was refused by the Privy Council in England in the year 1909. The decision was against the White Co., but later, in 1911, a merger was arranged and the Slocan Star Mines, Ltd., organized to acquire and operate both properties concerned, with Byron White as one of the directors and Oscar White as mine superintendent, since which time the property has been extensively further developed. Mr. White was well known and highly esteemed throughout the Northwest and especially in British Columbia, in the future of which he was a firm believer. He leaves a widow and one son.

SOCIETIES

International Trade Conference—A conference on international trade will be held at the Hotel Astor, New York, Dec. 6-8, under the auspices of the National Association of Manufacturers.

American Institute of Mining Engineers—The next meeting of the New York Section will be held Dec. 8, at the Machinery Club, 50 Church Street. The meeting will be preceded by a dinner served at 6:30 p.m. Following the dinner the subject of "The Engineer in Modern Warfare with Particular Reference to the Present Conflict," will be discussed by several U. S. army engineers.

INDUSTRIAL NEWS

The Morse Bros. Machinery and Supply Co. has purchased the entire plant of the Kuenzel process smeltery situated at Buena Vista, Colo., and will dismantle it and ship it to Denver. This plant was never completed and only parts of it were placed in operation. There is a complete power plant of high-pressure boilers, engines, blowers, compressors, besides crushing plant, machine shop, fire and boiler feed pumps, shafting, elevators, etc.

Editorial Correspondence

SAN FRANCISCO—Nov. 24

Employment of Negroes as Mine Laborers is reported to have been undertaken in the Coso district, Inyo County. More than 25 negroes passed through Visalia Nov. 7 en route to the mines. They came from Virginia and are said to be employed by eastern men who have recently taken hold of mining property in that district. It is reported that their compensation is to be $10 per month and board. The labor in the mines in California has for a long time been done by foreigners; and foreign labor is at present not plentiful. What effect the employment of negroes will have upon the labor element is problematical. This is the first time that a full crew of negro labor has been employed at mining work in California, although the employment of negroes in various other industries is common enough.

The Filing of an Injunction in San Bernardino County to restrain the sale of 3,500 acres of potash lands at Searles Lake as part of the estate of Pliney H. Perkins, while adding another chapter to the litigation, at the same time attracts further attention to the operations of the American Trona Co. The sale of the property involved in the estate has been postponed and the matter will be heard in the Superior Court. But the American Trona Co. is going along with the development of the process for recovering the potash from the brine of the lake, regardless of added litigation. The development of the Searles Lake deposits began before the European war was thought of in America. So the location and development of China Lake basin, a few miles west of Searles Lake, was begun before the war attracted renewed attention to the potash deposit in California. Charles H. Churchill, a prospector and miner who had been on the desert half a lifetime, and who was the discoverer of tungsten in San Bernardino County, has been engaged for several years locating and developing a large acreage of ground that he believes will produce potash and borax on a large scale. Whether or not the European war continues for a long period, the development of these potash lands both at Searles Lake and China Lake will no doubt be continued in the same spirit and with the same energy.

Standard Oil Co., has taken over the Kern County property of Monte Cristo Co., also the Monte Cristo lease at Fullerton. The price is said to be $375,000, which is considered very low. There is a quarter-section of the Maricopa and 40 acres at Fullerton. Total number of wells 115. Monte Cristo has produced a large amount of low-gravity oil. The Fullerton wells are deeper and produce a lighter-gravity oil. The Standard has also taken over a full section in the Antelope Hills district, Kern County, from the Oil Exploration Co., Ltd. The price is said to be $40,000. Testing operation has been in progress in the district for some time past. The Associated is very active in the Lost Hills district, having more than 100 men employed in section 13, plowing and leveling off locations for wells to be drilled. Teams and large motor trucks are working night and day in order to get material and supplies upon the ground before the winter rains start. About 20 wells will be drilled. Oil sands in this section lie 500 to 700 ft. deep. Oil is light gravity. The independent producers, while of a necessity having reduced their output in the past year, are aware that the purchases of more territory by the Standard and increased operation by the Associated is evidence of a future that cannot be destroyed even by the litigation instituted by the government. While the big companies are taking on more land and preparing for increased production, the marketing concerns are keeping their plants going largely with oil purchased from small producers. The only oil men who seem to be really discouraged are those on land that may be involved in the government litigation.

BUTTE—Nov. 25

More Development Work in Butte Mines is being carried on at present than at any time in the history of the district. On Nov. 1 the Rainbow Development Co. began work on its contract at the Butte & London. On that date the unwatering of the shaft was completed and the sinking of the shaft from the 1,100-ft. level to the 1,600-ft. level was begun. The shaft is now down close to the 1,200 level. By Apr. 1 the station on the 1,600 should be in and the entire property will then be crosscut from north to south. Sinking at the Rainbow shaft is going steadily forward and the two properties will be developed jointly. At the East Butte properties, which are to the south of the Rainbow and Butte & London, the sinking of the shaft of the Pittsmont mine came to a stop after going down a distance of 250 ft. from the 1,600 level. At that point a heavy wet fault was encountered that caused delay. The plans call for a further sinking there to the 2,100-ft. level. At the Tropic, adjoining these properties on the east, the Anaconda company will carry on sinking during the coming year and carry the shaft down to the 2,000-ft. level. The Blackrock shaft of the Butte & Superior has been carried down from the 1,600-ft. level to a depth of 1,920 ft. and crosscutting will be carried on from the 1,700-, 1,800- and 1,900-ft. levels. Sinking is now being carried on at the Butte & Great Falls property in the northeast part of the district. All of these mines are in what is known as the East and North Butte districts and in territory that has not heretofore been explored at depth. The unwatering of the Lexington, Alice, Nettie and Emma mines which is going on steadily will be followed by sinking in nearly all those shafts. Sinking at the Elm Orlu is now going forward steadily and the purpose is to carry the shaft from the 1,700 level down to the 3,000-ft. level with stations at 1,900, 2,000 and every 200 ft. below that to the lowest level. It is estimated that sinking in all the mines of Butte being carried to lower levels, is now averaging 2,500 ft. per month or a total of nearly half a mile each month in added depth to the Butte mine shafts.

The New Experimental Zinc Plant of the Anaconda company at the Washoe smeltery is claimed to be a complete success from a commercial as well as from a metallurgical standpoint. The costs, it is said, have been reduced to a point where zinc can be made at a profit even if it were to fall in price to the point where it started previous to the war in Europe. The Anaconda company is expected to proceed immediately with either the enlargement of the experimental plant at Anaconda or with the construction of a new plant in Great Falls, Anaconda or Butte. In the 10-ton experimental plant at Anaconda which was put into operation in October, three large melting pots are used. These were of old construction and limited in capacity. The company has now nearing completion a new brick furnace that will increase the capacity of the plant to 25 tons of zinc per day. This will make a monthly capacity of 1,500,000 pounds of electrolytic zinc when the new plant is operating at the full limit. Cakes of the new electrolytic zinc have been on exhibition in Butte and have attracted great interest in mining circles. This zinc is said to be of such a high grade, 99.9% pure, that it has found a ready market at a good premium by manufacturers requiring it for brass specials and munition purposes. An improvement that has been made is the use of aluminum starting sheets in the electrolytic process. Under the plan of operation adopted at first, aluminum starting plates were used to make zinc starting sheets. On each aluminum plate two zinc starting sheets were made and these in turn were taken off and used for starting the regular zinc plates in the electrolytic tanks. By using the aluminum starting sheets direct, this double handling is avoided. Two plates of zinc are formed on each aluminum starting sheet and are taken direct to the furnace after being removed from the tanks. The Anaconda company expects to have several mines with large zinc orebodies ready for operation early next year. Included in this list are the Emma which it has under lease, the Alice and the Lexington, all of which are being unwatered at present. It is now taking zinc ores for its experimental plant from the Poulin and East Gray Rock mines.

MIAMI, ARIZ.—Nov. 22

Construction at the Inspiration Mill is going on at a rapid rate. The building for the housing of all the pumps and compressors is nearly completed. The seven additional thickening tanks for the tailings-dewatering plant have yet to be installed. In the mill proper, the Marcy ball mills of nine of the 18 sections of the mill are in operation, 18 mills in all, there being two in each section. The flotation machines for the 8th and 9th sections have not been installed, the machines in the first seven sections having to treat the ore ground in the nine crushing sections in operation. The flooring for the flotation machines for the 11 uncompleted sec-

tions is now being laid and several of the cleaning flotation machines, namely in sections 8, 9, 10 and 11 are being erected, the corresponding roughing cells cannot of course be put in until the laying of the floor is completed. The machinery for the concentrating department for all sections has been installed and is ready for operation except for placing the steel drags on the belts of some of the drag classifiers. In sections 8, 10 and 11 flotation machines of the Inspiration type are being installed which are similar to the machines of sections 5, 6 and 7 except whereas those in the last mentioned sections are built of timber, the newer machines in sections 8, 10 and 11 are constructed of light sheet steel. In section 9, another type of flotation machine is being installed, built partly of wood and partly of steel. This machine will operate with agitating paddles somewhat like those used in the Minerals Separation machine, but from the appearance of the machine at present, as it is being installed, the agitation and flotation will take place in the same cell, the tank or trough of the machine being a simple rectangular box in the middle of each cell of which an agitator will hang. This type machine will make in all three types of flotation machines in the Inspiration mill, namely the Callow, the Inspiration and the agitator machines. In the flotation plant the odor of coal tar has replaced that of the eye-burning creosol and creosote.

Construction Work at the Inspiration Mine is nearly completed and for the last few weeks a general cleaning up has been under way both on the surface and underground. This work had consisted of clearing away temporary structures, litter, etc., that had accumulated during the construction period, which at the mine is now about closed. The road from Miami to the mine has been closed, making it necessary to go up to the mine by team or auto over the road that passes by the smeltery and mill. The ground to the west of the Captain shaft of the Miami Copper Co. is caving and cracks that crossed the road have been widening at a rapid rate because of the Miami company's caving operations going on underneath. The miner's change house at Inspiration is nearing completion, and will be ready for occupancy just as soon as the interior fittings have been completed. The double-deck Otis elevator, that will carry a total of 40 men, in the main west shaft is about ready for regular use, and will be used for lowering men by the time the change house is completed. This elevator is electrically lighted and is equipped with a telephone. It is operated from the deck by the cager exactly as is an office-building elevator. There are two push buttons at each station in the mine for calling the elevator for going up or down. It is said that this elevator is the fastest moving one of its kind, having been designed for a maximum hoisting speed of 850 ft. per minute. The electric controlling device installed by the General Electric Co. on the Nordberg twin-skip hoists is now in constant use. With this controlling mechanism the hoisting of the two skips in balance in each shaft is entirely automatic from the time the current is turned on at the beginning until turned off at the end of the shift; the hoisting engineer's most onerous duty is the oiling of the machinery. The hoists may be operated by hand whenever desired, the hoisting speed then being considerably greater than when operating under the automatic control. The last of the four crushing units in the coarse-crushing plant at the main hoisting shaft is now in commission; the conveying machinery on which delivery had been delayed has been installed so that the plant is now ready for operations at full capacity.

CLIFTON, ARIZ.—Nov. 20

A Petition for the Recall of Governor Hunt of Arizona, who is said to have headed a public subscription list with $500, asking at the same time that all citizens donate to the strikers' cause; who threatened to put the mine managers in the bull-pen in order to accomplish his desires regarding treating with the strikers; who issued a Thanksgiving proclamation of which this is a sample: "Today, in Arizona, whither, with phenomenal encompassment of distance, that lofty civilization inaugurated by our Puritan forefathers has advanced with irresistible tread in obedience to Destiny's decree, an intelligent, liberty-loving populace, mindful of the perpetual, omniscent guardianship of Divine Providence, adhere to a time-honored custom by gratefully acknowledging the beneficence of an omnipotent Creator with appropriate manifestations of gratitude for blessings bountifully bestowed," is being circulated in which one of the indictments is: "That the said George W. P. Hunt has deliberately attempted to foment and encourage class hatreds and divisions. That he has been partisan and prejudiced in his dealings with the most vital interests of the state and that, by a program of unconcealed and deliberate catering to the most radical elements, he has created a condition approaching anarchy in certain sections of the state."

TORONTO—Nov. 27

The Consolidated Mining and Smelting Co., of Canada, has issued a circular announcing the issue of a new block of stock, and giving a statement of the affairs of the company, which shows a remarkable expansion. The zinc output for 1916 has been ordered by the Canadian Shell Committee at profitable prices. At the request of the Shell Committee, the company has undertaken the refining of copper which will be done on a limited scale at first, but later it is expected to develop and involve the treatment of much of the matte and blister copper taken from British Columbia mines. The Shell Committee will take the output of refined copper during 1916. The capacity of the lead furnace has been taxed to its full extent during the past year, and the output is sold for six months ahead.

OTTAWA—Nov. 27

Antimony Deposits in the Wheaton district in Southern Yukon are declared by Dr. D. D. Cairnes, of the Geological Survey, who has made a thorough examination of them this year, to be among the largest antimony deposits in the world. In the White Horse copper belt the Pueblo mine, from which 100,000 tons of copper ore averaging 4% copper was shipped prior to the opening of the war, is about to begin operations again. About 100,000 tons of silver ore have been shipped this year from the Atkins mine, at Galena Creek, on the Upper Stewart River. Other promising silver properties are now being developed in the vicinity of the Atkins mine.

VICTORIA, B. C.—Nov. 22

Pacific Coast Collieries, which deferred its bond interest last May, has taken similar action again this month. The property was compelled to close down for a long period, but is now operating and the outlook for the future is better.

Silver Ingots Valued at $65,000 formed part of the cargo of the Nippon Yusen Kaisha liner Yokohama Maru on her last voyage to Hongkong. The silver was shipped via Victoria from the Consolidated Mining and Smelting Co.'s plant at Trail, B. C., and was the largest and most valuable that has yet been sent across the Pacific from British Columbia mines.

COBALT—Nov. 27

The Increase in the Price of Silver has resulted in a renewal of productive activity in the Cobalt camp, and companies which for some time have been curtailing their output and holding back shipments are now arranging to take advantage of improved market conditions by increasing production. In many cases development operations carried on steadily during the depression have put the companies in better condition for mining, so that if the present price is maintained a largely increased output may be anticipated. Mining staffs are being largely reinforced.

There is More New Exploration Work started or planned for this camp at present than there has been for several years. Much of this is by new interests not directly connected with the old successful companies and is on properties which have been partly explored in the early boom days or which have been idle after brief production under the stimulus of the boom. Most of the operations are financed from the States and they are largely in the charge of men new to the district who have been able to get control of well located properties on very good terms and who have their own private "hunch" as to where the ore is to be found. In most cases the work planned does not require a heavy capital outlay and this is presumably a feature that had caused these opportunities to become of interest again at this time. In fact, the camp has and does offer special opportunities for companies with limited capital. The hazard is very great, but the financial requirements of the work are relatively small considering the great prizes in prospect if ore is struck. Among the new projects already formed may be mentioned the Genesee, controlling a lot north of the Chambers-Ferland in the conglomerate, backed by Buffalo and Rochester people; the Twentieth Century, north of Cross Lake, near the Green-Mehan, financed in Buffalo; the Mercy, a survival of the Gould operation in the Cart Lake area, controlled by some of the Seneca-Superior crowd; the Cyril Lake or old Airgoid near the Dominion, backed by St. Paul and Duluth operators; the Adanac, south of the Temiskaming and supposed to have a continuation of the Temiskaming veins, sustained by Burr Cartwright, of Buffalo; the Aguinico, on Lake Temiskaming, north of Cross Lake, being opened chiefly for its cobalt ores by C. E. Smith, of Toronto; the Green-Mehan, once well known on the stock markets, now being unwatered and examined; the Casey-Seneca, in the Casey-Cobalt area, north of the main productive area and isolated from it.

The Mining News

ALASKA

CLIFF MINE (Valdez)—Wharf being rebuilt by Manager Ellis preparatory to shipping in spring.

BARNES PROPERTY (Crowe Creek, Seward)—Richard Dawson, driving tunnel ledge, reports ore averaging $14 per ton.

TEIKHELL (Teikhell District)—Pres. Joseph McCoy reports good progress in development of mine. Tunnels are being driven to tap lead of ore.

ALASKA ENDICOTT M. AND M. CO. (Juneau)—Incorporated with capital of $1,200,000, to own, operate, deal in mines, etc. E. M. Aldrich is Alaska agent.

KOYUKUK CLEAN UP—Will be in the neighborhood of $250,000 this year according to F. D. Howard, former commissioner for that district, most of the gold coming from Hammond River.

NEVADA CREEK (Douglas Island)—M. S. Hudson in charge of mine has added 20 men to crew and will push main tunnel during winter; 800 ft. additional tunneling will be started at once.

BLACK DIAMOND GOLD (Valdez)—C. C. Reynolds, George Hobart, H. Whitney, J. Crawford, G. J. Love and L. Graham are developing this property and report striking a 21-in. lead of free-milling ore.

SPEEL RIVER PROJECT (Juneau)—P. B. Dawson, connected with construction plans of Project has recently been at Speel River looking over proposed work. Reported that work will start in spring.

ALASKA GASTINEAU (Juneau)—During September 500,000 tons of ore were broken in Perseverance stopes. Mill at Thane milled 160,000 tons. Total cost of mining and milling under 60c. per ton. Original estimate was 75c. per ton. At Annex Creek Water-Power Project, water should be turned through power house by end of year. Tunnel finished and concreting well under way. A. G. M. Co. settled with H. T. Tripp of Juneau for water rights on Annex Creek and Carlson Creek for consideration of $10,000.

ARIZONA

Cochise County

CALUMET & ARIZONA (Bisbee)—Has leased a large tract of mineral land about 16 mi. east of Fort Stockton, Texas. Ostensibly, acquisition was made for purpose of drilling for oil, but there is opinion prevalent that it is sulphur the company is after. New Cornelia, a C. & A. subsidiary, has developed at Ajo, Ariz., large body of low-grade oxidized copper ore and is building big leaching plant. It is to supply this plant with sulphuric acid that sulphur is wanted. Local well-driller will immediately start to put down two 500-ft. holes.

Gila County

IRON CAP COPPER (Copper Hill)—Produced in October 179,847 lb. of copper at a cost of 9.3c. per pound. Net earnings were $15,065. For six months ended Oct. 31, made net profits of $85,274. Shaft is down to 900-ft. level, where station is being cut.

Greenlee County

FEDERAL INVESTIGATION of causes leading up to the Clifton strike began at Clifton, Nov. 22, following arrival of two commissioners of the Department of Labor.

THE WOMEN OF GLOBE AND MIAMI will aid the strikers' families at Morenci, Clifton and Metcalf by raising money through an entertainment and county fair to be given at Central Hall in Globe.

Mohave County

UNITED EASTERN (Oatman)—Final steps taken at annual meeting of stockholders looking toward immediate start of construction of 200-ton cyanide plant, to be increased later to 400 tons per day. Frank A. Keith is president, and D. C. Jackling and Seeley W. Mudd are on the board of directors.

CALIFORNIA

Amador County

RHETTA (Plymouth)—Grading for installation of machinery has begun and mine will be reopened. It was former producer.

MAYON (Amador City)—Sinking is progressing with view of thoroughly prospecting ground by drifting. Thomas C. Mayon is owner.

FREMONT (Dry Creek)—Reported that unusually rich ore has been disclosed in lower levels. Mine is and has been for number of years producer and dividend payer. Wales Palmer is superintendent.

PLYMOUTH CONSOLIDATED (Plymouth)—Preliminary statement for October shows 11,000 tons of ore milled, total value, $54,499; working costs, $29,301; development expenditure, $3,328; surplus, $21,870.

Butte County

FORBESTOWN CHROME shipped by Western Pacific, having been wagon-hauled to Oroville. Shipment amounted to 45 tons; mined on property of California Hardwood Lumber Co.

Calaveras County

CALAVERAS COPPER (Copperopolis)—Installation of new mill progressing; expected to be ready for operation in December; 90 men employed in mine and mill.

Eldorado County

JUDSON (Diamond Springs)—Pumping plant installed for unwatering shaft. Property has yielded large amounts in pocket gold.

MONTEZUMA (Nashville)—Plymouth Exploration Co., of Amador County, is putting mine in shape for active operation, sinking double-compartment shaft at rate of 80 ft. a month; now down 700 ft., will be deepened to 1,200 ft. before drifting; 3 shifts and 20 men employed.

Modoc County

SUNSHINE (Highgrade)—Schauer brase is sacking high-grade ore and hauling to New Pinecreek. Expect to have carload by Christmas.

Nevada County

MEADOW LAKE (Colefax)—George Cooper and Tom Harris have bonded property to Theodore D. Robinson, of Lakeport, N. Y.

GOLDEN CENTER (Grass Valley)—Reported that payment of $18,000 has been made by company to Nicholas Berriman for Bromedary claim which was located in 1850 and worked in early days.

MEDICAL EXAMINATIONS of miners ordered by North Star and Empire and Pennsylvania mines. Under recent amendments to law, employers are now responsible for care of men affected by occupational diseases.

Plumas County

WALKER COPPER (Portola)—Flotation plant, 100 tons capacity, being installed at mines near Portola. Expected to be in operation early in January. Construction of 4,600-ft. aerial tramway in progress; surface buildings being erected.

SOUTHERN EUREKA (Greenville)—Reported that George D. Needy, of Spokane, and other Washington men have purchased this property, including Hibernia and McClellan mines; also the Wardlow group adjoining Southern Eureka. Property embraces about 450 acres in center of Greenville district and is surrounded by producing mines. Installation of modern mill contemplated.

Sierra County

WISCONSIN (Forest City)—Gold nugget weighing nearly 9 oz. found, also quartz boulders thickly studded with gold. Many rich nuggets found here in past. Property operated by Wisconsin-North Fork Mining Co. through same shaft as old North Fork gravel mine. G. F. Stone, manager.

Shasta County

MAMMOTH (Kennett)—New copper orebody reported in gossan croppings north of the Mammoth proper. Development at this point was undertaken for purpose of securing quartz ores.

Tuolumne County

HOPE (Sonora)—Air-driven pumps and air drills are to be installed; 12 men are employed in development work. Property is owned by Salt Lake City men. George W. Weston is general manager.

RAWHIDE (Jamestown)—Large amounts of machinery and supplies being received from Blair, Nev., by Silver Peak Mining Co., which recently purchased property. Said to be purpose of company to move entire plant from Blair to Jamestown.

COLORADO

Clear Creek County

MARY MINES AND LEASING (Idaho Springs)—This company, composed of local operators, has started development on Mary vein. Work will be carried on through Big Five tunnel.

IMPERIAL MINES (Georgetown)—Lessees operating on Centennial vein have opened 14-in. vein of $50 ore for distance of 70 ft. Operations are being carried on through Wilcox tunnel.

CAPITAL CENTRAL (Georgetown)—Development which has been in progress during past few months has disclosed body of milling ore which will probably be shipped to Linn mill for concentration.

SPECIE PAYMENT GOLD (Idaho Springs)—Systematic development is to be resumed in this company's property on Bellevue Mt. and preliminary operations are under way. New work is under direction of E. J. F. Coleman who is president and manager of the company.

Teller County

C. O. D. (Cripple Creek)—Lessees Parsons and Vetters, operating on 10th level, have made rich strike. Discovery was made in raise extended from 10th level at point about 750 ft. north of the shaft. Pay streak is 30 in. wide and is composed of quartz and fluorite. Assays indicate value of about $150 a ton. Discovery is on what is considered split from main C.O.D. vein and is about 800 ft. below surface.

IDAHO

Shoshone County

IMPERIAL (Wallace)—Operations have been resumed in lower workings, 720 ft. below upper workings and 1,200 ft. below surface. John H. Nordquist is manager.

GUELPH (Wallace)—New shaft down 25 ft. Sinking is by hand, but company plans to install compressor and drills, taking current from lines of Washington Water Power Co.

LITTLE PITTSBURGH (Kellogg)—Compressor delivered at property, which is under bond to Colonial Mining Co. Electric power line has been extended to run compressor. Property opened by crosscut 650 ft. and drift on vein 40 ft. shows 20 ft. of zinc ore, 2 ft. of which assays 47% and balance 26%. Company will ship high-grade ore, delivering it to wagon road by tramway and hauling to railroad about 8 mi.

EMPIRE (Little North Fork)—Compressor has been delivered to this property, formerly known as Horst-Powell, and power lines are being extended to mine by W. W. Power Co. Company has considerable ore blocked out and plans mill in spring. Several shipments made during summer.

BOSS ZINC (Osburn)—Has about 2 ft. zinc-lead ore in short crosscut from bottom of shaft. Much development work in that section for many years has failed to disclose commercial ore, although surface indications and formation are highly favorable. Strike on Boss is therefore of more than usual interest.

SNOWSTORM (Mullan)—Rumor that Snowstorm company had taken over Banner & Bangle property at Troy, Mont., denied by Leo Greenough, manager, who states that Snowstorm has two other properties under consideration. Greenough interests have been developing Banner & Bangle for several years and plan construction of 300-ton mill next spring. Ore is lead-zinc.

SUNSET (Wallace)—This property, acquired many years ago by ex-Senator W. A. Clark, of Montana, which has been under active development by him during recent years, is to have new electrically driven compressor and hoist. Present power is gasoline, with which shaft has been sunk 400 ft., with drifts east and west at 200 and 400. Shaft will be sent deeper with new plant. Has large body of low-grade lead and zinc ore.

GALENA GROUP (Wallace)—Situated on Ninemile west of Success, will be developed by Cœur d'Alene M. and S. Co. Winze sunk to depth of 60 ft. from short upper tunnel, disclosed promising body of galena and carbonate ore; work in winze was stopped because of difficulty of handling water. Second tunnel was driven at 500 ft. lower elevation, cutting vein 900 ft. from portal. Company will drive on vein 400 ft. to get under winze.

RED MONARCH (Wallace)—Red Monarch Consolidated Mining Co. has been organized, combining Red Monarch, Rawhide and Emerald groups of claims in Beaver district. Spokane men are controlling factor in organization and are now preparing for extensive development. Two well-defined veins will be explored, one of them running in an easterly and westerly direction and the other north and south. Contract has also been made with diamond-drill company to do 8,000 ft. of exploration.

MICHIGAN

(Iron)

YOUNG (Iron River)—New lease has been granted. Mine will be unwatered and worked this winter. This is one of last mines in Iron River field to be reopened.

METEOR (Ironwood)—Shaft-sinking will be resumed here. Depth of about 200 ft. was reached when work was stopped two years ago. Considerable work must be done before ore is reached.

CLEVELAND-CLIFFS IRON CO. (Ishpeming)—Last boat was loaded Nov. 23. Cargo was from Republic mine. Snow hindered loading operations at mines. Company shipped more than 2,225,000 tons. Most of other Marquette range companies are also through for year.

CLEVELAND-CLIFFS IRON CO. (Ishpeming)—A shaft is to be sunk on Junction Forty and ore removed. This land adjoins Section 16 mine of Oliver Iron Mining Co. Latter company worked to Junction line. Intention was to have Oliver remove ore. This could not be done, as Section 16 shaft is handling all ore it can. Diamond drills are at work on surface and underground in Sixteen to locate best place for new shaft. Deposit is large and of good grade.

FORTUNE LAKE MINING CO. (Crystal Falls)—This company will not go ahead with its development work at present. Contractors have stopped their work of changing course of Briar Hill Creek. No houses will be erected. Two big shafts will not go down. Lands were drilled first with churn drills. Later, few diamond-drill holes were put down. It is reported that the ore showed from 1 to 3% sulphur. This would make it of little value at this time. All of lands have not been explored. More drill work will be carried on shortly.

MINNESOTA

Duluth

ZENITH FURNACE CO. (Duluth)—Now manufacturing benzol and toluol as byproducts of coke manufacture.

RALSTON STEEL CAR CO.—Company negotiating for site for $2,000,000 plant near the Minnesota Steel Co. plant at Duluth. Present plant and office are at Columbus, Ohio.

Cuyuna Range

CUYUNA-MILLE LACS (Ironton)—Season's shipments will total 10,000 tons. Product, high-manganese iron ore, with 10 to 35% manganese content

BREITUNG (Crosby)—After loading all equipment on cars and abandoning operations, orders were received to resume work at this development shaft.

Mesabi Range

BELGRADE (Elba)—New shaft being sunk and new station will be cut.

BANGOR (Aurora)—Shaft now down 300 ft. will be sunk to greater depth during winter.

SECTION 27 (Chisholm)—Engine and dynamo being erected preparatory to installing electric-haulage system.

CLARK (Chisholm)—Steam-heated pockets being installed at shafthouse to prevent ore from freezing before loading. Shipments to be made throughout the winter to the Minnesota Steel Co. at Duluth.

MISSOURI—KANSAS—OKLAHOMA

TEMPLE CHATMAN (Miami, Okla.)—Has let contract for drilling of several hundred acres southwest of Miami.

GREENFIELD & LOCKWOOD (Lawton, Kan.)—Has new 150-ton mill about ready to start. Expects to have ground drained by time mill is ready to run. Had to increase pumping capacity.

LOCKPORT MILL (Galena, Kan.)—Important improvements being made at mill, situated on James Murphy land. Three of latest model sludge tables being installed. Mill runs exclusivcly on custom work. Will be ready for operation in about four weeks. William Crockett is superintendent.

LUCKY GEORGE (Joplin, Mo.)—R. C. Watson, superintendent. Building new 200-ton mill. The company has 15-acre lease on Lindeman tract of land at Bell Center, northwest of Joplin. Two shafts already in ore; expect to have both of them opened up ready for operation by time mill is completed. Trial runs at custom mill showed that dirt would run 10% zinc ore.

AYLOR (Joplin, Mo.)—A 300-ton mill is going up on Aylor land. E. A. C. Elliott is superintendent. Two pumps have been running for some time to drain ground. Present work will be conducted at 180-ft. level, where good run of ore has been encountered, but good pay dirt is claimed to extend to 220-ft. level. Company has drilled eight holes, all of which are said to show same ore that is now being opened up in mill shaft at 180-ft. level.

MONTANA

Lincoln County

MINING ACTIVITY NEAR TROY—Leo Greenough, well known mining man, is preparing for considerable activity on Grouse Mountain, few miles south of Troy, where he is operating B. & B. mine. Projected electric railroad from Troy to mine will be constructed immediately and mill of sufficient size to handle big output will be put up. Mr. Greenough has secured options on other mining claims on Grouse Mountain.

Silver Bow County

BUTTE-ALEX SCOTT (Butte)—Earnings for October were slightly over $30,000 or an average of over $1,500 per day for 20 days which mine was operated. November will show still better results according to advices from mine.

BUTTE-BALLAKLAVA (Butte)—October earnings were over $1,000 a day, best showing made since company took over management at time lessees were working property. Ore hoisted averaged more than 4½% copper and was mined from levels between the 1,300 and 1,600. Crosscutting is being done on 2,200 level.

LILLIE MINE (Butte)—On Nov. 24 Judge McClernan entered decree for partition of Lillie claim between North Butte and Butte-Main Range companies. Latter owns five-sixths, former one-sixth of Lillie claim. By agreement Butte-Main Range gets what is known as north portion of claim, containing 7.817 acres. North Butte gets southern portion, containing 8.811 acres. Being worth more than north portion, North Butte is to pay $30,000 to Butte-Main Range company.

BUTTE & SUPERIOR (Butte)—According to quarterly report for three months ended Sept. 30, net earnings were $2,761,839. Ore mined and milled, 130,210 dry tons, averaging 17.147% zinc and resulting in production of 37,396 tons of concentrates averaging 55.123% zinc, corresponding to recovery of 92.32%. Mining costs were $3.46 per ton, milling costs $1.77 per ton. According to report filed in federal court 43,000 tons of ore were treated in Minerals Separation plant during October at cost of $2.75 a ton, to recover 10,473 tons of concentrates valued at $79.77 a ton.

ANACONDA (Butte)—Butte mines of Anaconda were compelled to close down two days during last week on account of surplus of ore that it was impossible to handle at Washoe and Great Falls reduction plants of company. Average daily production of 19 operating shafts of company is 13,600 tons of ore. Two-day shut down enabled smelters to catch up and it is not anticipated that any further curtailment of mining output will be necessary as improvements at both Anaconda and Great Falls will be completed soon after Jan. 1 and capacity of smelting plants increased by 20%. While most of ores from Butte are going to Anaconda, Great Falls plant is helping out to considerable extent. Three sections of old mine of which was shut down year ago with expectation that it would never be started again, are caring for 1,500 tons of ore daily and making about 500 tons of concentrates. Six of the eight sections in old concentrator plant at Anaconda have been reconstructed and work on two remaining sections is being rushed. By Jan. 1 it is estimated that Great Falls and Washoe plants will be able to handle daily output from Butte mines of Anaconda company of 15,000 tons and copper production will be raised to above 25,000,000 lb. per month. Officers of company expect that copper production for next year will reach 300,000,000 lb. Neverswent mine, last of large operating shafts of company that is shut down, is now in readiness to start up at any time that conditions require it. New hoist is in position and shaft has been retimbered its entire length, making it one of best-equipped mines of district.

NEVADA

Esmeralda County

JUMBO EXTENSION (Goldfield)—October production was 3,476 tons; gross value, $112,000. Total mining costs were $16,000. Smelting, freight and treatment amounted to $32,000 and smelting losses $14,000. Net realization for month, $50,-000. Velvet shaft is now down 700 ft. and connections will be made with present workings on 780, 860 and 1,017 levels.

Humboldt County

NEVADA PACKARD (Rochester)—New mill being tuned up; crushing ore. Mine has produced 2,300 tons of ore, average value $48.21 per ton, and there are 36,000 tons, average value of $15, blocked out. There are 7,000 tons already broken ready for the mill.

ROCHESTER MINES CO. (Rochester)—Friedman tunnel has cut vein at depth of about 1,300 ft. exposing 44 ft. of vein

matter, several feet of which is of good milling grade. Level of tunnel is about 700 ft. below bottom of workings from which present production is being made. It is estimated that November production will be $55,000.

Nye County

TONOPAH ORE PRODUCTION for week ended Nov. 20 amounted to 10,093 tons valued at $207,634 compared with 9,189 tons week previous. Producers were: Tonopah Belmont, 2,998 tons; Tonopah Mining, 3,150; Tonopah Extension, 1,850; West End, 612; Jim Butler, 1,050; North Star, 53; and miscellaneous leasers 380 tons.

TONOPAH BELMONT (Tonopah)—During October 12,342 dry tons of total net value of $142,206 were milled, resulting in profit of $65,069.

TONOPAH MINING (Tonopah)—During October mill treated 12,435 tons; average value of $12.80 per ton, resulting in profit of $60,700.

JIM BUTLER (Tonopah)—October production was 4,604 tons resulting in profit of $27,067, compared with $22,232 profit for September.

TONOPAH EXTENSION (Tonopah)—Profits for October amounted to $66,000, compared with $52,000 for September. Increased profit due largely to excellent conditions at No. 2 shaft where stoping continues from 750 to 1,350 levels. Crosscut from 1,540 level of Victor shaft should cut Murry vein within next 140 ft.

Storey County

CROWN POINT-BELCHER (Gold Hill)—Saved 235 cars milling ore from 1,600 level. Jacket mill treated usual tonnage and shipped bullion.

MEXICAN (Virginia)—East crosscut 2,700 level in porphyry and quartz of low assay at 33-ft. point. Winze in east crosscut No. 2 sunk to 11-ft. point; 2- to 4-ft. vein matter, from low assay to $30 per ton. Reopening west crosscut on 2,500 level. Mill crushed 162 tons custom ore, average assay $29.74 per ton.

UNION (Virginia)—Top of raise in No. 1 stope 2,500 level in ore assaying $21 per ton. Saved 55 tons, average assay $26.70 per ton. Northwest drift from sill floor in low-grade ore. From south end No. 3 stope 2,500 level saved 88 tons, average assay $43.71 per ton. Wedge rock saved from north end of stope in cutting out for timbers.

OPHIR (Virginia)—Low-grade quartz in south drift 2,500 level. At 145-ft. point south of winze 4 ft. of low-grade quartz. Central tunnel 250 level north drift shows 8 ft. of ore in face. Saved 365 cars of ore from stopes above north and south drifts. Milled 328 tons. Advanced Con. Virginia and Ophir west crosscut on 2,700 level to 70-ft. point.

NEW MEXICO

Dona Ana County

VICTORIA MINING AND SMELTING CO'S silver-lead holdings were bought by C. T. Boyd, of Los Angeles, at sale ordered by U. S. District Court to satisfy bankruptcy proceedings. Properties comprise about 1,000 acres of mineral lands in two groups about 20 mi. apart. Southern group is between Organ and San Andras mountains and the northern group is situated in the Plomo district in San Andras about 35 mi. northeast of Las Cruces. New company will start extensive developments immediately.

UTAH

Beaver County

CEDAR TALISMAN (Milford)—Since beginning shipments of zinc ore from 600 level, company has produced 10 cars ore carrying about 30% zinc.

NORTH AMERICA (Milford)—Work is to be resumed at this property adjoining Croff mine on south. Ore carrying lead and silver is exposed on 180-ft. level.

GALENA (Frisco)—Work has been resumed at this property near Horn silver. Tunnel is being driven to cut fissure productive of lead-silver ore in past years. Tunnel is in 185 ft., with about 200 ft. to go.

Juab County

MAY DAY (Eureka)—Small cyanide plant operated by Griggs, Carter & Castleton on ore from May Day dump has been closed down for winter.

TINTIC STANDARD (Eureka)—Preparations for sinking new working shaft being made. This is to do away with lack of air in the lower workings, property having only one opening to surface.

YANKEE (Eureka)—Second car of ore has been shipped from recent strike near surface. This is reported to have carried 180 oz. silver and $6 to $8 in gold, making value for 50-ton car about $4,500.

LOWER MAMMOTH (Mammoth)—Zinc ore is being mined on 1,500, 1,700 and 1,800 levels. During September 3 cars were shipped and 2 in October. Company has good surplus in treasury. Copper and lead-silver ore being mined on 1,000 level.

IRON BLOSSOM (Silver City)—New deposit of copper ore opened in winze from 600 has been drifted on 70 ft. Several shipments have been made from here, but no stoping has yet been started. New stope has been opened in north end of mine on 500 level.

EAGLE & BLUE BELL (Eureka)—Practically all of stock of Victoria company has been turned in in exchange for Eagle & Blue Bell stock. It is probable that as soon as new equipment at latter property has been installed, work through Victoria shaft will cease, and development in that ground will be carried on through Eagle & Blue Bell workings.

COLORADO (Silver City)—$60,000 in stocks, securities and personal checks has been turned over to the clerk of the United States district court to satisfy judgment in the suit of J. L. Wilson against company for alleged deferred dividends. Sum is to satisfy all claims and liens against company, various attorneys' liens having been filed for division of judgment. Division will be made without participation of defendant company. Decision in favor of company by local Federal court was reversed by circuit court of appeals.

Salt Lake County

UTAH CONSOLIDATED (Bingham)—This company is shipping 250 tons of lead ore daily, in addition to shipments of copper ore.

CARBOFF (Salt Lake)—Work is being done with machine drills, since electrical equipment and new 8-drill compressor have been installed. Tunnel is being straightened and laid with 25-lb. rail. Electric haulage is to be used. Shipments are being maintained at rate of 125 tons daily, and it is thought that roads can be kept open during winter.

Summit County

PARK CITY SHIPMENTS for the week ended Nov. 20 amounted to 1,300 tons, valued at $52,000, as compared with 1,078 tons week previous.

NEW YORK BONANZA (Park City)—Work will soon be resumed here.

SNAKE CREEK TUNNEL (Park City)—Progress during October amounted to 312 ft., making total length 13,025 ft.

SILVER KING CONSOLIDATED (Park City)—From 30 to 40 tons of high-grade ore are being shipped daily. A two-mile tunnel is being considered to develop western end of ground.

THREE KINGS (Park City)—Company has sunk double compartment shaft 600 ft., and has drifted 400 ft. to south. The work is at present in limestone, and drift is being driven to reach contact with underlying Ontario quartzite. Electric hoist, electrically driven compressor, etc., is being used. The company owns 160 acres, adjoining Silver King Coalition and Silver King Consolidated. Operating shaft is in Nigger Hollow. E. S. Fisher is general manager.

Utah County

AT AMERICAN FORK, throughout the winter season, it is expected that a larger number of properties than usual will continue work. Lessees at the Pacific have recently shipped car of lead-silver ore of good grade, and fissure carrying lead-silver ore also is reported to have been cut at Bellerophon.

Washington County

AT THE NEW GOLD CAMP OF GOLDSTRIKE in the former Bull Valley district near Modena work continues. At Hamburg, whose strike of rich gold ore near surface was cause of recent activity in district, middle tunnel is being driven to cut ore in winze from upper workings. New ore is reported in Goldstrike Virginia, Primers Fraction and Goldstrike Bonanza.

CANADA

British Columbia

SALMON-BEAR RIVER GROUP (Portland Canal)—Main adit tunnel is now in 350 ft. and is expected to reach orebody in another 150 ft. Group is under bond to H. R. Plate, of New York.

CANADA COPPER CORPORATION (Greenwood)—Has taken up subject of new financing for construction of new plant to cost $2,000,000. Engineers report that there have been developed to date at Copper Mountain 8,900,000 tons of "proven" ore averaging 1.75% copper and 2,000,000 tons of "partially" proven ore averaging 1.75% or a total of 10,900,000 tons, and an estimated 20c. recoverable per ton in gold and silver. Erection of 2,000-ton plant is recommended. Canadian Pacific engineers are assured of advisability of running a spur to mines from Princeton, 12 mi. Greenwood ores are smelted direct, whereas Copper Mountain ores are of disseminated porphyry type and will require concentration by flotation process.

Ontario

LAKE SHORE (Kirkland Lake)—Is again in operation. Sinking to 200 is being carried on.

TEMISKAMING (Cobalt)—Mill has 40 stamps but only 20 have been running; remaining 20 are to be put in commission.

SCHUMACHER (Porcupine)—Has sunk main shaft to 600 level. Two hundred thousand shares, par value $1, are to be put on market at 50c. a share.

SENECA-SUPERIOR (Cobalt)—Operating costs are only about 5c. per oz. Statement as of Nov. 20 showed cash in bank of $180,000 in addition to $59,500 received for sale of ore.

McINTYRE EXTENSION (Porcupine)—Has reached the 850 level. Some ore has been developed and will be treated in the McIntyre mill when the additions are completed, which will be about the first of year. Mill capacity will be increased 50%.

HOLLINGER (Porcupine)—Contract for headframe over central shaft has been let to Dominion Bridge Co. Winding engine to be installed here will be of 5,000 tons' capacity raising 5-ton skips and capable of raising ore from depth of 3,000 ft.

HURONIA (Larder Lake)—Option on this property held by Canadian Mines and Finance Co. has been allowed to lapse. Considerable work was done on property and fair quantity of ore developed. Oreshoots were short, however, and amount of money involved was large in comparison with value of ore.

PLENAURUM (Porcupine)—Has been unwatered and is now being sampled by engineers from La Rose mine. If examination is satisfactory, La Rose will purchase 59,500 shares of treasury stock at $1 share; money to go into development. After expenditure of this money sufficient vendors' stock can be purchased to give control.

MEXICO

Sonora

GREENE-CANANEA (Cananea)—One section of concentrator was equipped with apparatus of the Minerals Separation, Ltd., process several months ago, but the mill-run from July to mid-September, between enforced shutdowns, was not long enough to demonstrate what the process would do on ores from the Cananea-Duluth mine, which will constitute the principal tonnage on which flotation will be tried out.

The Market Report

Metal Markets

NEW YORK—Dec. 1, 1915

In all of the principal markets there was diminished activity and a tendency toward softening of prices, with the exception of lead.

Copper, Tin, Lead and Zinc

Copper—The demand for copper began to wane early in the week and in the latter portion the market became rather dull, although some round lots were sold on Tuesday. The aggregate volume of business transacted during the week was materially less than in the previous week. However, the total of November business was very large, perhaps as large as that which was done in June, which was a remarkable month. Early in the week some copper was sold at 20c., r. t., but the market never became fully established at that figure, sales being made at the same time at 19¾c., r. t. Within the range of 19¾@20c., r. t., producers were disposed to accept any bids that were made to them, and also any reasonable opportunities to dispose of copper abroad regardless of just what foreign sales might net. Business in England was taken at about £98 throughout the week. There was a tendency to accept bids for copper to be delivered later than February at slightly lower terms than for delivery during the immediate quarter. In the latter portion of the week copper was to be had so freely at 19¾c., r. t., that the terms of 20¼ and 20c. which were asked by some producers no longer cut any figure in the market.

Copper Exports for the week ended Nov. 13 are reported by the Department of Commerce at 18,874,973 lb. The larger items were 9,650,928 lb. to France, 4,831,591 lb. to Italy, 1,805,897 lb. to England and 1,459,788 lb. to Sweden. Imports were 2,739,439 lb. metal and 2,883,574 lb. in ore and matte; 5,623,013 lb. in all. The chief imports were from Chile, Cuba, England and Japan.

Copper Sheets, base price is 25c. per lb. for hot-rolled and 26c. for cold-rolled, with usual extras. Copper wire is 21@21½c. per lb., carload lots at mill.

Tin—Business was light and the market was very narrow. Orders to buy or sell even in moderate quantities would influence it sharply one way or the other. The deliveries in November were relatively small, being only 2,975 tons—2,575 on the Atlantic Coast and 400 on the Pacific Coast.

Tin output of the Federated Malay States is reported at 40,487 long tons in 1914, and 38,636 in 1915; decrease 1,851 tons.

Imports of tin ore and concentrates in Great Britain in October were 3,210 long tons; of which 2,491 tons were from Bolivia and 494 tons from Nigeria.

Tin arrivals at Pacific ports of the United States 11 months ended Nov. 30, were 1,412 long tons, being 117 tons less than last year.

Lead—The firmness of the market in St. Louis and the narrowness of difference between the prices at St. Louis and at New York would normally foreshadow an advance in New York. The A. S. & R. Co. maintained its price of 5.25c., but independents made sales at 5 to 10 points higher. The freight congestion on the railways entering New York is playing a part in the New York lead market, shipments of lead from St. Louis to New York being considerably longer on the way than normally.

The prices of the American Smelting and Refining Co. for desilverized lead delivered in several markets are as follows: St Louis, 7½ points under the New York price; Chicago, 5 points under; Detroit and Cleveland, 2½ points over; Pittsburgh and Philadelphia, 5 points over.

Spelter—Producers reported relatively small business in the early part of the week, after which there was utter absence of demand, and the market passed largely in the hands of dealers. There was a weakening tendency right through the week and on Dec 1 a distinct softening. The large difference between the prices for prompt and later deliveries continues, producers being willing to accept relatively low prices for deliveries a little way forward.

The Russo-Asiatic Corporation expects to have one unit of the zinc-smelting plant that is to treat the ore of the Riddersk mine ready for operation next March.

Zinc Sheets are in good demand, but have not advanced this week, and the base price today is $22 per 100 lb., f.o.b. Peru, Ill., less 8% discount.

Other Metals

NEW YORK—Dec. 1

Aluminum—The market shows no change, metal for early delivery being scarce and in good demand. The current price is 58@62c. per lb. for No. 1 ingots, New York. Futures are not quoted.

Antimony—The market remains strong, and there have been some fair-sized dealings. Ordinary brands, chiefly

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St Louis is given as the basing point St Louis and New York are normally quoted 0.17c apart

The quotations for electrolytic copper are for cakes, ingots and wirebars Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash The difference between the price delivered and the New York cash equivalent is at present about 0.20c on domestic business The price of electrolytic cathodes is 0.05 to 0.10c below that of electrolytic Quotations for lead represent wholesale transactions in the open market for good ordinary brands. Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St Louis being the basing market We quote the New York price at 17c per 100 lb. above the St Louis price.

Silver quotations are in cents per troy ounce of fine silver

Some current freight rates on metals per 100 lb. are: St Louis-New York 17c., St Louis-Chicago, 6.3c., St Louis-Pittsburgh, 13.1c.

LONDON

Nov.-Dec	Copper Standard Silver	Copper Standard Spot	Copper Standard 3 Mos.	Copper Electrolytic £ per Ton	Copper Electrolytic Cts. per Lb.	Tin Spot	Tin 3 Mos	Lead £ per Ton	Lead Cts. per Lb.	Zinc £ per Ton	Zinc Cts per Lb.

1	26⅞	80	80½	99½	20 95	166¼	165½	28½	6.09	99	20.86

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 5 per cent. discount. For convenience in comparison of London prices, in pounds sterling per 2240 lb., with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4.80 £15 = 3.21c.; £20 = 4.29c.; £30 = 6.43c.; £40 = 8.57c.; £60 = 12.85c. Variations, £1 = 0.21½c.

Chinese, are selling around 40c. per lb. for large lots, while up to 42½c. has been named on some smaller business. Cookson's is nominally held at 52c., with very little to be had.

Antimony ore is available only in small lots and $2.40@2.50 per unit is named.

Quicksilver—Stocks are not large and prices are at a high level still and are advancing. New York price is $110 per flask of 75 lb. for large lots and $110@115 for smaller orders. San Francisco reports by telegraph $105 per flask, with very small stocks. London price continues £16 10s. per flask, with no discount from second hands.

Minor Metals—Current quotations for **Bismuth** are $3 per lb., New York.—**Cadmium** is quoted at 7s. per lb. in London; $1.75@1.90 per lb., New York.—**Chromium metal,** 75c. per lb., New York.—**Cobalt metal,** 97% pure, is sold at $2 per lb.—**Magnesium,** pure, has gone to a high price, $6 per lb. being asked.—**Selenium** varies from $2.50@3 per lb., New York, for large lots; $4.50@5 for retail quantities.

Gold, Silver and Platinum

NEW YORK—Dec. 1

Gold and silver movement in the United States 10 months ended Oct. 31 is reported by the Department of Commerce as follows:

	Gold		Silver	
	1914	1915	1914	1915
Exports	$207,958,750	$15,874,980	$42,453,190	$40,795,086
Imports	45,886,949	345,560,373	20,515,394	28,504,357
Excess	E. $162,071,801	I. $329,685,393	E. $21,937,796	E. $12,290,729

Exports of merchandise for the 10 months are valued at $2,867,123,745; imports, $1,450,624,406; excess of exports, $1,416,499,339. Adding the gold and silver gives $1,052,585,421 as the total export balance.

For the 10 months ended Oct. 31 imports of gold at San Francisco increased from $4,091,964 in 1914 to $54,033,016 in 1915: the gain being due chiefly to receipts from Japan. Exports were $461,995 for the 10 months.

Platinum—The market is still uncertain and prices high. Dealers are unwilling to make regular quotations, and there are negotiations over almost every transaction. Sales have been made as high as $70 and even $74 per oz. for refined platinum and up to $77@78 per oz. for hard metal.

Our Russian correspondent writes under date of Nov. 5 that a persistent demand both from abroad and for the internal market continues. The prices have again increased. The offer of metal is less than the demand and therefore higher prices are expected. From Ekaterinburg it is reported that, owing to the high prices, abandoned mines with low content are being put at work, and it is hoped that this will increase the offer of platinum; but the large dealers are persuaded that prices will not be reduced, as the demand is too high.

Palladium—Some sales of palladium are reported at $45@50 per oz., according to size and terms of order

Silver has advanced by sudden bounds about 1d. per oz., English standard, owing to the discovery that the stock in London was much less than expected. It is reported at about 7,000,000 oz. The higher price has brought out sellers and some reaction is probable should there be free selling at the advance.

Zinc and Lead Ore Markets

JOPLIN, MO.—Nov. 13

Blende, high price $118; base per ton 60% zinc, premium ore, $115; medium, $111@105; lower grades down to $100; Calamine base per ton 40% zinc, $80@70; average selling price, all grades of zinc, $101.24 per ton. Lead, high settling price $71.50, base per ton 80% metal content, $70@71; average selling price, all grades of lead, $67.84 per ton.

SHIPMENTS WEEK ENDED NOV. 27

	Blende	Calamine	Lead	Values
Totals this week	15,262,560	3,048,140	1,760,310	$986,600
Total 11 months	535,072,200	41,709,700	82,910,180	24,497,080

Blende value, the week, $820,110; 11 months, $21,227,610.

Calamine value, the week, $106,790; 11 months, $1,061,870.

Lead value, the week, $59,700; 11 months, $2,207,600.

The total shipment of 9,155 tons of zinc eclipses all previous records of sales, and is the strongest point marking the demand for zinc ore. The 4,000 tons stock at Granby is more than half gone and much of that remaining is sold for future delivery. Also a large portion of the Miami reserve has been sold and is being shipped. Elsewhere no large stocks have accumulated. Tonight the miners are threatening a strike if producers do not raise wages, but this is premature with many of the stronger companies which have a wage agreement based on the average base price of ore the preceding month.

PLATTEVILLE, WIS.—Nov. 27

The base price paid this week for zinc ore was $108 per ton for 60% grades. No sales of lead ore were reported.

SHIPMENTS, WEEK ENDED, NOV. 27

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	6,076,000	.....	840,320
Year	189,643,750	6,338,640	26,524,310

Shipped during week to separating plants, 5,518,000 lb. zinc ore.

Iron Trade Review

NEW YORK—Dec. 1

The iron and steel markets continue to be extremely active, with heavy demand for both home consumption and export, while higher prices seem hardly to check the demand.

One exception to this is the withdrawal by the Pennsylvania R.R. of its order for 11,000 cars, on account of the high prices asked. In other cases, however, advances seem to make little difference, the rush being to secure material for delivery when needed. The export business is still a very large factor in the market.

Pig iron is quite as active as steel and prices are being firmly held at the advances made. Steel-making irons are in special demand with low-phosphorus also.

The statement comes from Philadelphia that the Reploglе-Drexel syndicate has secured enough Cambria Steel stock in the market, in addition to that bought from the Pennsylvania R.R., to give them control of the company, and that plans for its reorganization will soon be brought forward. It is certain that there has been heavy buying of the outside stock.

PITTSBURGH—Nov. 30

Effective Dec. 1 the American Steel and Wire Co. is advancing wire products $2 a ton, making plain wire 1.85c. and wire nails $2 per keg, base. The general advancing tendency in steel prices is somewhat less pronounced. There is less pressure to place strictly new business, perhaps simply because early deliveries could not be secured, while there is heavier specifying on contracts.

A further quieting down in new buying is to be expected for December, while specifying on contract will doubtless be less active in the first quarter, on account of the higher range of contract prices, but the mills will enter the new year with nearly six months of solid work on their books, and there is no expectation in any quarter of any weakening whatever in the steel market for many months.

Lake Superior iron-ore prices for next year have not been closed and while an early announcement is expected in some quarters there is a contingent in favor of waiting until after Jan. 1 for the naming of prices.

Pig Iron—Pig-iron prices have been advancing very sharply, and all grades are quotable at $1 higher than a week ago. Apparently there is scarcely any unsold capacity for the next four or five months. We quote: Bessemer, $18@18.50; basic, $17; malleable and foundry, $17@17.50; forge, $16.50@17, f.o.b. Valley furnaces, 95c. higher delivered Pittsburgh.

Ferromanganese—The market has stiffened. Imported is firm at $100, seaboard, on contract, and domestic producers are firm at $110, shipping point, as minimum. Prompt lots go at $100@105 per ton.

Steel—The market is quiet as regular consumers have made private arrangements with their regular sources of supply and chance comers have no standing at all with producers who are indisposed to sell except when there is a direct obligation to take care of a regular customer. The market, such as there is, can be quoted at about $1 higher than a week ago: Bessemer billets, $28; bessemer sheet bars, $28@28.50; openhearth billets, $29@30, openhearth sheet bars, $29.50@30, f.o.b. maker's mill, Pittsburgh or Youngstown.

Chemicals

NEW YORK—Dec. 1

The general market is fairly steady, with few changes reported, and business inclined to be more active.

Arsenic—A moderate business is forward and little or no change is noted. Quotations are $3.75@4 per 100 lb. for both spot and futures.

Copper Sulphate—Business is quiet and on about the usual scale. Quotations are unchanged, at $8 per 100 lb. for carload lots and $8.25 per 100 lb. for smaller parcels

Nitrate of Soda—Prices keep up well, though arrivals have been large. Quotations continue $2.90 per 100 lb. for December and $2.85 for later deliveries.

Pyrites—Imports at Baltimore for the week included 9,876 tons pyrites from Huelva, Spain.

Mining Companies—United States

The Mining Index

This index is a convenient reference to the current literature of mining and metallurgy published in all of the important periodicals of the world. We will furnish a copy of any article (if in print) in the original language for the price quoted. Where no price is quoted, the cost is unknown. Inasmuch as the papers must be ordered from the publishers, there will be some delay for the foreign papers. Remittance must be sent with order. Coupons are furnished at the following prices: 20c. each, six for $1, 23 for $5, and 100 for $15. When remittances are made in even dollars, we will return the excess over an order in coupons, if so requested.

COPPER

2336—ALASKA—Mining on Prince William Sound. Bertrand L. Johnson. (Bull 622-E, U. S. Geol. Surv., 1915; 8½ pp., illus.)

2337—ARIZONA—Copper Queen Reduction Works, Arizona. C. A. Tupper. (Min. and Eng. Wld., Nov. 6, 1915; 3¼ pp., illus.) 20c.

2338—ARIZONA—The Bisbee-Warren District—Copper Queen Mine. C. A. Tupper. (Min. and Eng. Wld., Oct. 2, 1915; 8 pp., illus.) 20c.

2339—ARIZONA—The Strike Situation in Arizona. (Eng. and Min. Journ., Oct. 30, 1915. 1¾ pp., illus.) 20c.

2340—BRITISH COLUMBIA—The Britannia Mine, Howe Sound, B. C. E. A. Haggen. (Min., Eng. and Elec. Rec., Aug., 1915; 21½ pp., illus.) 20c.

2341—CALIFORNIA—The Geology of Iron Mountain. Oscar H. Hershey. (Min. and Sci. Press, Oct. 23, 1915; 6 pp., illus.) 20c.

2342—CHILE—Mining Methods at Braden. (Eng. and Min. Journ., Nov. 20, 1915; 1⅔ pp.) From article by H. R. Graham in "Teniente Topics." 20c.

2343—COLORADO—Gold, Silver, Copper, Lead and Zinc in Colorado in 1914. Mines Report. Charles W. Henderson. (Mineral Resources of U. S., 1914—Part I. Oct. 16, 1915; 59 pp.)

2344—CONCENTRATOR—The Concentrator of the Braden Copper Co. ("Teniente Topics," Oct., 1915; 5½ pp., illus.) 40c.

2345—ELECTRICAL INDUSTRY—Copper and Electrical Industry. (Elec. Wld., Nov. 6, 1915; 3 pp., illus.) 20c.

2346—LEACHING—Nevada-Douglas Con. Copper Co.'s Process of Ore Leaching. A. J. Orem. (Min. and Eng. Wld., Oct. 16, 1915; 2¼ pp., illus.) 20c.

2347—PHILIPPINES—Copper Deposits in Zambales Province. V. E. Lednicky. (Mineral Resources of the Philippine Islands for 1914; 3 pp.)

2348—PULVERIZED COAL for Copper Smelting, Anaconda Copper Mining Co. N. L. Warford. (Min. and Eng. Wld., Nov. 6, 1915; 2¾ pp., illus.) 20c.

2349—REFINING—Electrolytic Refined Copper. A. C. Clark. (Advance copy, Internat. Eng. Congress, Sept., 1915; 9 pp., illus.)

2350—SMELTING at Panulcillo, Chile. (Eng. and Min. Journ., Nov. 13, 1915; 2¾ pp., illus.) Account of operations of Central Chili Copper Co. 20c.

2351—TAILINGS—Potash in Certain Copper and Gold Ores. R. S. Butler, with a note on Muscovite, by G. Steiger. (Bull. 620-J, U. S. Geol. Surv., Nov. 15, 1915. 12 pp.) On the possibility of recovering potash from tailings obtained in the concentration of gold and copper ores.

2352—UTAH—The Disseminated Copper Ores of Bingham Canyon, Utah. J. J. Beeson. (Bull., A. I. M. E., Nov., 1915; 45 pp., illus.)

GOLD AND SILVER—GEOLOGY

2353—ALASKA—The Willow Creek District, Alaska. Stephen R. Capps. (Bull. 607, U. S. Geol. Surv., 1915; 86 pp., illus.)

2354—ARIZONA—Gold Deposits Near Quartzite, Arizona. Edward L. Jones Jr. (Bull. 620-C, U. S. Geol. Surv., Sept. 23, 1915; 13 pp., illus.)

2355—BRAZIL—The Geology of Central Minas Geraes, Brazil. E. C. Harder and R. T. Chamberlin. (Journ. of Geology, July-Aug., 1915; 40 pp., illus.) 60c.

2356—PHILIPPINES—Notes on the Mineral Resources of Surigao Province. Wallace E. Pratt. (Mineral Resources of the Philippine Islands for 1914; 7½ pp.)

2357—TASMANIA—The Geology of the Waihi Grand Junction Mine. Arthur Jarman. (Bull. 133, I. M. M., Oct. 14, 1915; 45 pp., illus.)

GOLD DREDGING AND PLACER MINING

2358—ALASKA—The Willow Creek District, Alaska. Stephen R. Capps. (Bull. 607, U. S. Geol. Surv., 1915; 86 pp., illus.)

2359—ALASKA—Winter Mining at Fairbanks. Hubert I. Ellis. (Eng. and Min. Journ., Oct. 30, 1915; 4¼ pp., illus.) 20c.

2360—ARIZONA—Gold Deposits near Quartzite, Ariz. E. L. Jones, Jr. (Bull. 620-C, U. S. Geol Surv., 1915; 13 pp., illus.)

2361—BRITISH COLUMBIA—Acquiring Placer-Mining Claims in British Columbia. J. A. Macdonald. (Eng. and Min. Journ., Nov. 6, 1915; 1⅔ pp., illus.) 20c.

2362—PHILIPPINES—Gold Mining in Various Districts in 1914. Wallace E. Pratt. (Mineral Resources of the Philippine Islands for 1914; 7½ pp.)

2363—SAVING FINE GOLD. T. W. Gruetter. (Min. and Sci. Press, Nov. 6, 1915; 5¼ p.) 20c.

2364—VICTORIA—Dredge Mining and Hydraulic Sluicing in Victoria. (Annual Report of the Chief Mining Inspector for 1914. 16 pp.)

2365—YUKON—Mining in the Yukon. (Can. Min. Journ., Nov. 1, 1915; 7¼ pp., illus.) From "The Yukon Territory," by J. B. Tyrrell, in "Canada and Its Provinces," Vol. 22. 20c.

GOLD AND SILVER—CYANIDING

2366—CYANIDE CONSUMPTION on the Witwatersrand. H. A. White. (Journ. Chem., Met. and Min. Soc. of So. Afr., Sept., 1915; 11¾ pp.) 60c.

2367—MERCURY DETERMINATION—The Determination of Mercury in Cyanide Solution and Precipitate. W. J. Sharwood. (Min. and Sci. Press, Oct. 30, 1915; 2 pp.) 20c.

2368—SOLUTIONS—The Prevention of Hydrolysis in Cyanide Solutions. H. M. Leslie. (Journ. Chem., Met. and Min. Soc. of So. Afr., Sept., 1915; 13½ pp., illus.) 60c.

2369—SOUTH DAKOTA—Trojan Ore and Milling Practice. Jesse Simmons. (Min. and Sci. Press, Nov. 6, 1915; 3⅜ pp., illus.) 20c.

2370—TUBE MILLS—The Use of Scoop Discharges in Tube Mills. W. R. Dowling. (Journ. Chem., Met. and Min. Soc. of So. Afr., Sept., 1915; 2½ pp.) Discussion of paper previously indexed. 60c.

GOLD AND SILVER—GENERAL

2371—ARIZONA—The Oatman, Ariz., Mining District. (Min. and Eng. Wld., Nov. 13, 1915; 3 pp., illus.) 20c.

2372—COLORADO—Gold, Silver, Copper, Lead and Zinc in Colorado in 1914. Mines report. Charles W. Henderson. (Mineral Resources of U. S., 1914—Part I. Oct. 16, 1915; 59 pp.)

2373—IDAHO—Metallurgy in the Cœur d'Alenes. Herbert A. Megraw. (Eng. and Min. Journ., Nov. 20, 1915; 4 pp., illus.) 20c.

2374—PHILIPPINES—Gold Mining in Various Districts in 1914. Wallace E. Pratt. (Mineral Resources of the Philippine Islands for 1914; 7½ pp.)

2375—PHILIPPINES—Gold Production of the Philippine Islands in 1914. Wallace E. Pratt. (Mineral Resources of the Philippine Islands for 1914; 1½ pp.)

2376—SOUTH DAKOTA—Trojan Ore and Milling Practice. Jesse Simmons. (Min and Sci. Press, Nov. 6, 1915; 3⅜ pp., illus.) 20c.

2377—SUMATRA—Erz und Kohle auf Sumatra. P. Muller-Herrings. (Glückauf, Sept. 25 and Oct. 2, 1915; 12 pp., illus.) 40c.

2378—TAILINGS—Potash in Certain Copper and Gold Ores. R. S. Butler, with a note on Muscovite by G. Steiger. (Bull. 620-J, U. S. Geol. Surv., Nov. 15, 1915; 12 pp.) On the possibility of recovering potash from tailings obtained in the concentration of gold and copper ores.

2379—TAILINGS Reclaimed by Cableway at Goldfield, Nev. John Sinclair. (Min. and Eng. Wld., Oct. 23, 1915; 2 pp., illus.) 20c.

2380—UTAH—The Daly-Judge Mine and the Snake Creek Tunnel. Will C. Higgins. (Salt Lake Min. Rev., Oct. 30, 1915; 5½ pp., illus.) 20c.

IRON ORE DEPOSITS, MINING, ETC.

2381—BRAZIL—The Geology of Central Minas Geraes, Brazil. E. C. Harder and R. T. Chamberlin. (Journ. of Geology, July-Aug., 1915; 40 pp., illus.) 60c.

2382—LOUISIANA—Iron-Bearing Deposits in Bossier, Caddo and Webster Parishes, Louisiana. Ernest F. Burchard. (Bull. 620-G, U. S. Geol. Surv., Oct. 22, 1915; 22 pp., illus.)

2383—PHILIPPINES—Iron Ore in Surigao Province. Wallace E. Pratt and Victor E. Lednicky. (Philippine Journ. of Sci., Sept., 1915; 13 pp., illus.)

2384—PHILIPPINES—Iron Ore on Calambavanga Island, Mambulao, Camarines. Wallace E. Pratt. (Philippine Journ. of Sci., Sept., 1915; 9 pp., illus.)

2385—PHILIPPINES—Notes on the Mineral Resources of Surigao Province. Wallace E. Pratt. (Mineral Resources of the Philippine Islands for 1914; 7½ pp.)

2386—TEXAS—Iron Ore in Cass, Marion, Morris and Cherokee Counties, Texas. Ernest F. Burchard. (Bull. 620-E, U. S. Geol. Surv., Oct 23, 1915; 41 pp., illus.)

IRON AND STEEL METALURGY

2387—ALLOY STEELS. George L. Norris. (Advance copy. Internat. Eng. Congress, Sept., 1915; 10 pp.)

2388—ALLOY STEELS in Modern Industries. Edgar D. Rogers. (Iron Tr. Rev., Oct. 28, 1915; 2⅜ pp.) Paper before Am. Iron and Steel Inst. 20c.

2389—BLAST FURNACE—Bosh Fuel Domes. Frederick Louis Grammer. (Proc. Engrs. Soc. W. Penn., Oct., 1915; 12 pp.) 60c.

2390—BLAST FURNACE—Thermal Principles of the Blast Furnace. J. E. Johnson, Jr. (Met. and Chem. Eng., Nov. 1 and 15, 1915; 12¾ pp.) Continuation of article previously indexed. 80c.

2391—BLAST-FURNACE GAS—Brûleurs a Gaz de Haut Fourneau, Système Birkholz. (Génie Civil, Sept. 25, 1915; ½ p., illus.)

2392—BLAST-FURNACE GAS, Utilization of. A. N. Diehl. (Iron Tr. Rev., Oct. 28, 1915; 3½ pp.) Abstract of paper before Am. Iron and Steel Inst. 20c.

2393—CARBON STEEL—The Effect of Carbon on the Physical Properties of Heat-Treated Carbon Steel. J. H. Nead. (Advance copy, A. I. M. E., Feb., 1916; 17 pp., illus.)

2394—CHEMISTRY—Contributions of the Chemist to the Iron and Steel Industry. Albert on S. Cushman. (Journ. Ind. and Eng. Chem., Nov., 1915; 1 p.) 60c.

2395—CHEMISTRY—Contributions of the Chemist to the Steel Industry. Geo. W. Sargent. (Journ. Ind. and Eng. Chem., Nov., 1915; 1¾ pp.) 60c.

2396—ELECTRIC FURNACES—New Electric Steel Furnaces. (Elec. Rev., London, Oct. 8, 1915; 3 pp., illus.) 40c.

2397—HEAT-TREATING STEEL Automatically. Thaddeus F. Baily. (Iron Tr. Rev., Oct. 28, 1915; 1 p.) Paper before Am. Iron and Steel Inst. 20c.

2398—MANGANESE-STEEL CASTINGS in the Mining Industry. Walter S. McKee. (Advance copy, A. I. M. E., Feb., 1916; 13 pp., illus.)

2399—MOTOR—A Large Steel-Mill Motor Drive. (Elec. Wld., Nov. 13, 1915; 1 p., illus.) Features that governed selection of a 1,600-hp. geared motor at plant of Atlanta (Ga.) Steel Co. 20c.

2400—PIPES—Wrought Iron or Steel Pipes vs. Cast Iron. L. C. Wilson. (Eng. Mag., Nov., 1915; 7½ pp.) Supplements a previous article on the influence of different elements on the corrosion of iron. 40c.

Flotation of Silver-Lead Mineral at a New South Wales Mine

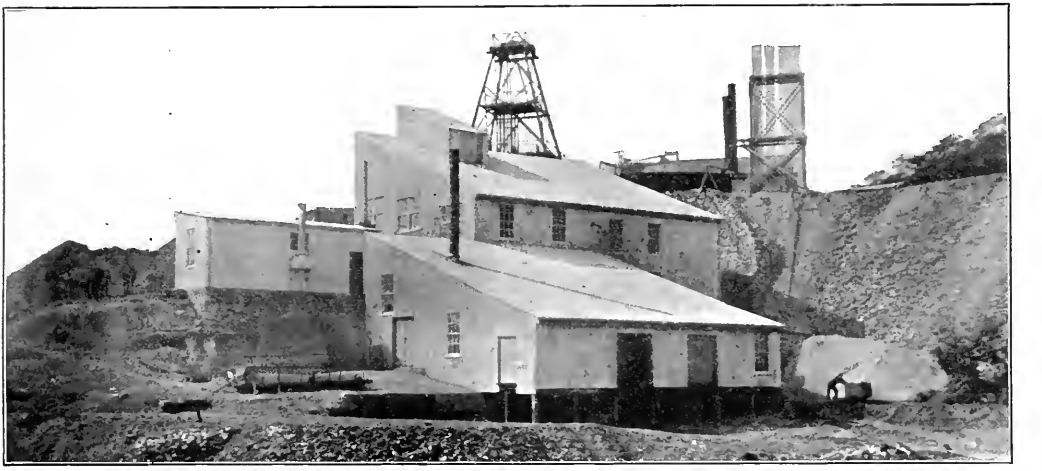
By H. Hardy Smith*

SYNOPSIS—A plant designed to treat a complex silver-lead ore where table concentration would not work. Many difficulties were met and surmounted, among which were a contaminated water-supply and much scale formed in the flotation machine. An original method of froth removal was devised. Details of practice fully discussed.

The small mill described in this article was erected at the Silver Peak mine for the purpose of treating the second-grade ores of the Yerranderie silver-lead mining field, New South Wales, Australia. Owing to the distance of the field from smelting works and the high cost of transport, over bad roads by horse teams, only the richest ores could be shipped at a profit. The question of smelting locally was studied, but owing to the highly siliceous nature of the "seconds" (about 70% SiO_2) and the difficulty of procuring suitable fluxes, the idea was abandoned.

The question of concentration was then considered, the problem proving to be a difficult one. The metallic minerals in the ore were, in order of importance: Galena, pyrite, marcasite, arsenical pyrite, blende, chalcopyrite and small quantities of secondary minerals from all the foregoing.

All these minerals carried silver to a greater or lesser extent, but the chief silver-bearing constitutents were the galena, and the iron sulphides, especially the marcasite. The galena occurred in two crystalline forms, one coarse and the other fine, the latter having a fracture similar to hard cast iron. This was rich in silver. Being extremely soft and friable, it slimed badly on crushing. Some of the ore contained it in such a fine state of dissemination that it appeared as a dark streak through the quartz, necessitating very fine grinding to free the values.



GENERAL VIEW OF THE SILVER PEAK FLOTATION MILL, VICTORIA, AUSTRALIA

The gangue was chiefly a hard glassy quartz with small quantities of felsitic country rock. From this description of the ore it will be readily understood that concentrating it was not simple.

Experiments were first made with gravity concentration, but the recoveries, especially of the silver, were low. The coarsely crystalline galena presented no difficulties, being amenable to jigging and table concentration; but this type was relatively low in silver, and the fine-grained variety, carrying the greater part of the silver, slimed so badly that no system of gravity concentration could give satisfactory recoveries. Flotation concentration was therefore tried, and as good results were reported from

*Suan mine, Holkol, Chosen.

small-scale tests made by Minerals Separation, a plant incorporating that process was decided upon.

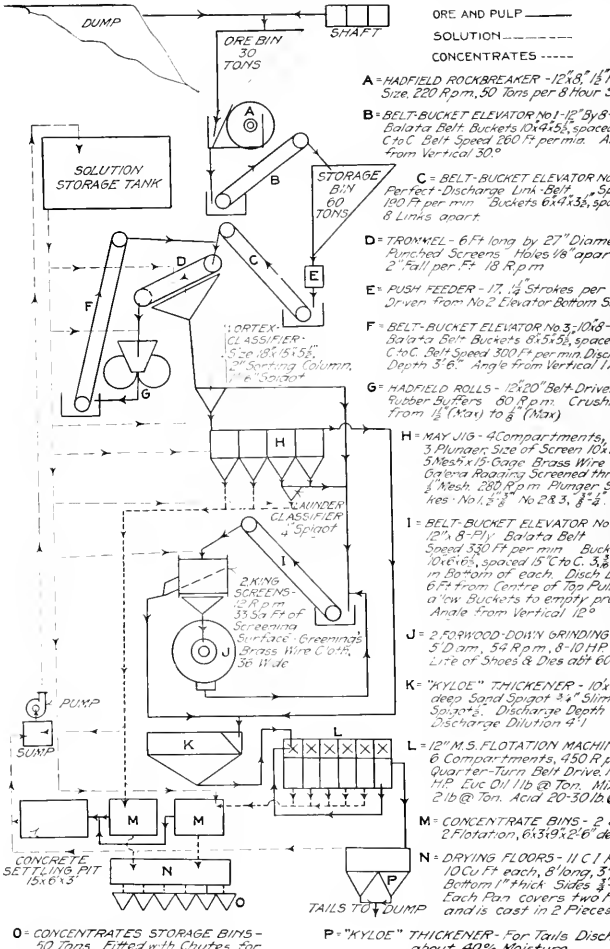
The average assay of the ore to be treated was about 30 oz. silver, 10% lead and 1 to 2 dwt. gold per ton. Because of the excessive transportation charges, the aim was to recover as much as possible of these metals in the form of high-grade concentrates. As the orebodies on the field were narrow and limited in extent, the company desired a mill of small capacity (about 50 tons per day) and small capital cost, which proviso precluded anything of an elaborate nature in the design. Several thousand tons of "seconds" had been mined during the opening up of the high-grade shoots of ore and lay awaiting treatment. The plan was to get the mill started and "tuned up" on this ore, supplementing it with ore from current development and, on results proving satisfactory, to mine the second-grade ore on an extensive scale. The flowsheet of the mill as erected is shown in the accompanying drawing.

The thickener before the flotation machine was of the inclined-baffleboard type already described.[1] They are cheap to build and simple and efficient in operation. The clear overflow from the thickener ran to the pump sump. The thickened underflow ran to a 6-compartment, 12-in. standard Minerals Separation machine. The tailings from the Minerals Separation machine ran to another thickener, the clear overflow from which ran to the pump sump, and the thick overflow into trucks and thence to the dump.

The flotation concentrates ran to a pair of bins, one being filled while the other was settling and being emptied. The turbid overflow from these bins ran to a concrete-lined pit where it was allowed to settle completely, the clear overflow from the pit running to the pump sump. This pit was cleaned out at intervals. After siphoning off the excess water from a concentrates bin, the sloppy concentrates were shoveled onto cast-iron drying floors and when dried sufficiently, into bins which fed chutes leading to the bagging floor.

The jig concentrates were handled similarly. On starting up the plant the first serious difficulty encountered was in the regrinding section, which could not handle the tonnage, when grinding to the degree of fineness required for good work at the flotation section. With the idea of lightening the load on the pans, the rolls were set hard up with considerable pressure between them so as to act by choke crushing. The increase in the quantity of slimes produced was immaterial owing to the ability of the flotation plant to handle this product efficiently. This readjustment made some improvement, but not sufficient to make up the leeway, and finally coarse screens had to be put on the King screening machines, increasing the aperture from 0.015 in. to 0.024 in. This resulted in a product altogether too coarse for good work at the flotation section, a point which must be kept in mind when considering the results.

The pulp as it left the regrinding section had a dilution of about 15 to 1 and before being treated at the flotation plant this was reduced to 4 to 1 in a Kyloe pulp thickener, the surplus water being returned by pump to the mill-water supply tank.



COMPLETE FLOW SHEET OF THE SILVER PEAK MILL

Oils Used in the Flotation Plant

The treatment at the Minerals Separation flotation plant involved the use of heat, acid and two oils. *Eucalyptus amygdalina* was used as an emulsifying agent and a dark lubricating-oil mixture to maintain the froth. The

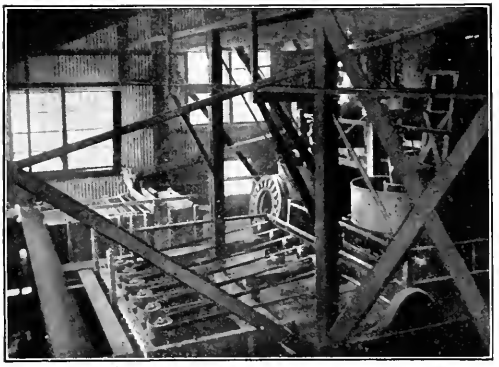
[1] "Flotation Process at Ryloe, N. S. W.," "Eng. and Min. Journ.," Dec. 7, 1912.

pulp was heated to 120° F. by live steam introduced into No. 1 agitating box. The consumption of steam was heavy, being equivalent to about 10 hp. (noncondensing) even when the initial temperature of the pulp was kept at about 90° F. by passing some of the mill water through the engine condenser.

The consumption of the different kinds of reagents varied considerably with the different kinds of ore, but the average was about as follows: Acid, 20 to 30 lb. per ton; *eucalyptus amygdalina*, ¾ to 1½ lb. per ton; mineral-oil mixture, 2 to 2½ lb. per ton. The sequence and method of using the reagents had to be altered from time to time to overcome difficulties that cropped up in the treatment.

Necessity for a Clean Water-Supply

One of the early difficulties encountered was of a peculiar kind and is well worth recounting. The water-supply for the mill was drawn from a dam, fed partly by surface drainage and partly by water from the mine. For four years previous to the commencement of milling operations this water supply had not been drawn on and had simply evaporated and soaked away. A few days



INTERIOR OF THE FLOTATION MILL

after starting the plant the water became discolored, first to a greenish yellow, then through yellow to a brick red. As soon as this reddish water arrived at the flotation plant the process went out of commission. The trouble seemed to be a total absence of aëration, which no amount of eucalyptus oil or other reagent could remedy. As much as 50 c.c. of eucalyptus oil was added to No. 1 agitating box at one time without producing any real froth or any signs at the back of the flotation spitz of the violent ebullition that is characteristic when the machine is in good working order. Occasional "blobs" of air came to the surface, but nothing in the shape of a froth.

The red discoloration was due to a fine precipitate which on analysis seemed to be a basic sulphate of iron. The precipitate was soluble in excess of acid, but the consumption made this remedy impracticable. The trouble was finally overcome, partly by keeping the mill solution in closed circuit and partly by manipulation of the reagents. Even with the closed circuit the loss by evaporation and leakage amounted to about 5,000 gal. per shift and this had to be made up with mine water.

This method of working led to another difficulty in the shape of scale and incrustations which formed chiefly in the Minerals Separation machine, but also in the screens and settler. In the flotation spitz the deposit took the form of sponge-like masses of crystals, while in the agitating boxes, in spite of the strong scouring action of the impellers, it was like a bad boiler scale. Both types dropped off at intervals and blocked the valves and pipes in the machine. At one period the trouble became so acute that it looked as if the plant would be a complete failure. The deposits were first noticeable when the solution contained only 150 grains of salts per gal. of solution, and up to a certain point they increased with the density of the solution. The incrustation appeared to be fine sand and slime bound together with sulphate of lime and magnesia.

At the King screens the meshes of the wire cloth became badly blinded. After a week or ten days the screening area became so reduced that the screens could not handle the tonnage, so the wire cloth had to be removed and cleaned by pickling in weak acid solution and then scrubbing with stiff wire brushes. The changing of the cloth on this type of screen is quite a tedious operation, and much time was lost thereby.

Samples of scale were assayed and showed in the deposit from the flotation spitz 61 oz. Ag and 14.5% Pb and in the deposit from the agitating boxes 16 oz. Ag and 3.5% Pb. The residue after evaporating filtered solution assayed 4 oz. Ag and 1.2% Pb, showing that small quantities of both silver and lead were being dissolved.

Device for Removing Floating Froth

The removal of the float from the surface of the flotation spitz presented another difficulty. When the machine was doing its best work the float was dense and heavy, being more of the nature of a thick scum than the usual frothy float composed of a fairly light mixture of bubbles and coagulated sulphides. The usual method in a case like this is to use paddles, but here they were ineffective as the float would not feed forward under the paddles. If the paddles were run fast and dipped deep, so as to cause a forward suction, the slime was stirred up and overflowed the lips with the concentrate, making it low-grade.

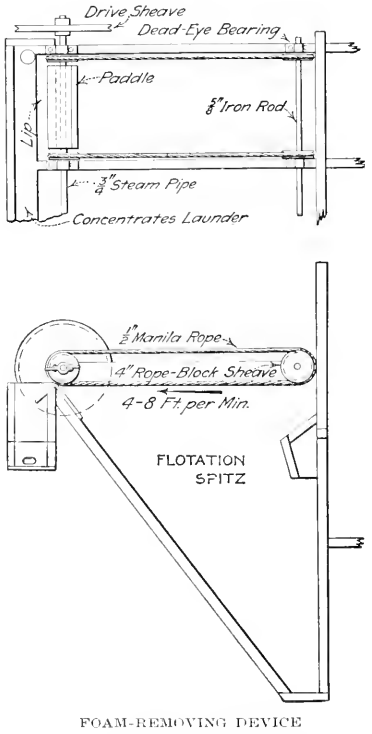
To overcome the difficulty the device shown in the sketch was put in. It consists simply of a pair of ropes traveling forward along both sides of the spitz. A ¾-in. pipe was run along the front of the spitz boxes, mounted on three simple bearings. To this pipe, 4-in. rope sheaves were keyed, two to each spitz. Along the back of the boxes a ¾-in. iron rod was run and another set of 4-in. sheaves threaded on and held in place by pins through the rod so that they could revolve freely without moving sideways. One-half-inch manila rope was spliced on over the sheaves. The ¾-in. pipe was driven at a very slow speed by a long rope from a slow-moving countershaft in the mill. Different-sized driving sheaves were kept handy so that the speed of the rope rabbles could be altered when necessary. It varied from 4 to 8 ft. per min. for the different classes of ore.

A coil of rope was kept handy, and a template was marked on a bench so that as the ropes wore they could be replaced rapidly by new ones. The ropes were put on with a rough long splice, and the men soon became expert enough to replace a rope in a few minutes. While one rope was out of business, the other did the work fairly well. Once the amount of shrinkage had been determined and allowed for, this characteristic of manila rope caused no trouble, its hairy nature made it effective, and this

combined with its low cost, made it preferable to rubber or composition bands. After about 12 months, the back sheaves had to be renewed.

If the surface of the water was kept within ¼ in. of the lips these rope rabbles would feed the float into the launder, but as this close regulation of the water level was difficult, very small paddles were mounted between the sheaves on the front pipe so as to dip just behind the lips and touch the froth over.

The assays of the floats from the various spitz boxes are shown in Table 2. The overflow from No. 6 spitz was always, and that from 4 and 5 sometimes, returned to No. 1 agitating box for retreatment. A retreatment scheme for the whole of the concentrates in a separate machine, though highly desirable under the conditions, was not feasible—first, on account of the extra cost of



FOAM-REMOVING DEVICE

plant and treatment, and second, because the amount of concentrates produced (from 3 to 5 tons per 24 hr.) was not sufficient to keep a machine adequately supplied.

Washing Concentrates to Improve Grade

In spite of all precautions the bulk concentrate from the machine ran about 15% insoluble. To improve this a scheme for washing the concentrates in the settling bins was introduced. The bin was fitted with a number of inclined removable baffles, and behind the first one a heavy spray of cold water was played on the float. This had the effect of disintegrating it so that the sulphides, still in the form of coagules, settled to the bottom at the same time a portion of the floated gangue was carried over a lip by the slow-moving current of water. The solids in the overflow assayed 50 oz. Ag, 10% Pb and 70% insoluble.

The average value of the mill concentrates is shown in the table:

	Au., Dwt.	Ag., Oz.	Pb, %
In jig concentrates	6.0	69.4	21.5
In flotation concentrates	7.4	115.7	19.6

The mill tailings ran from 8 to 12 oz. Ag per ton, under 10 grains Au, and 2 to 2.5% Pb. The proportion of jig

6	49.0	9.0	50.6

concentrates to flotation concentrate was about 2 to 1. The recoveries for the whole mill averaged only about 70% of the silver and 75% of the lead. In considering these low recoveries it must be remembered that during the period under review the plant was operating under two great disabilities—first, the inadequate regrinding facilities, and second, the fact that during the whole time, except for a few days toward the end, the plant was operated only one shift of 8 hr. per day. To give an idea of the importance of the former, a complete grading analysis of the feed and products from the flotation plant is given in Table 3. In columns 25 and 26 the recoveries made on each grade are given. Note the low recoveries on the coarser grades. It is not until the —100 to +150 grade is reached that anything like respectable recoveries are effected. The heads which remain on 80 screen contain 687.4 oz. Ag (by addition in column 5). The corresponding tailings contain 599.8 oz. (by addition in column 21), which represents a recovery of only 12.7%. The heads which pass an 80-mesh screen contain 1,285.6 oz. Ag, while the corresponding tailings contain only 312 oz., which represents a recovery of 75.7%.

Had the whole of the heads been ground to pass an 80-mesh screen, the —80-mesh product would have been enriched by 687.4 oz., bringing the total up to 1,937 oz.; while, assuming that the extra tonnage of —80-mesh product would not affect the recovery made on that grade (if anything it should improve it), the —80-mesh tailings would be increased by 34.3% of 687.4 oz., or 235.8 oz., bringing the total loss in the tails up to 547.8 oz., which would give a total recovery of 72.2% of the silver.

The recovery under the existing conditions was only 53.8%, so that by grinding the whole of the feed to pass an 80-mesh screen the recovery would have been increased at least 18%, making the total recovery for the mill about 90% of the silver. Unfreed values were not altogether

responsible for the losses due to the coarse crushing. Much of the free mineral itself was in pieces too large to be successfully floated. This was especially the case with the iron minerals and the finely crystalline galena. The large particles of coarsely crystalline galena appeared to float more readily. A good tailing of fairly coarse free mineral could be obtained by panning a sample of tailings which had been allowed to weather for some time so as to overcome the tendency of the sulphides to float off. So that better recoveries could have been expected if the sands had been passed over concentrating tables before being treated at the flotation plant. It would probably prove more economical to crush fairly fine, say not more than 15% on 80-mesh, and to table the sands, than to crush the whole product through 80-mesh and rely exclusively on flotation for the recovery of the sulphides. But here again, at this mill, the limited capital available was the governing factor.

Germans in the Metal Market

In the Court of Appeal, Nov. 18, 1915, Lords Justices Swinfen Eady, Phillimore and Pickford heard an appeal by Aron Hirsch & Sohn, metal merchants and smelters, of Halberstadt, in Prussia, from a decision of Justice Bray in an action brought against them by the Zinc Corporation, Ltd., of Copthall Avenue, E. C., says the London *Financial Times*. The action was for a declaration that a contract for the supply of zinc concentrates from certain mines in Australia to Hirsch & Sohn was void by reason of the war.

J. A. Compston, K. C., for Hirsch & Sohn, said that his clients had for a long time been taking the total production of zinc concentrates from certain mines in Australia. On the outbreak of war this action was brought. In it two questions were raised: (1) Was the contract one of a class which would be dissolved by the war? (2) If it were, was there not a clause in it which would suspend the operation of the contract during the war, and therefore prevent it being dissolved? Justice Bray held that this was a contract that would be determined by war. The second point gave him considerable trouble. He did not decide it and could say no more than that he inclined to the opinion that war was one of the things that would bring the suspensory clause into operation; but he said all that was suspended were future deliveries. That left in the contract clauses that would operate, and as they would necessitate communication with the enemy, the contract was void. On these grounds a declaration was granted, but without prejudice to all contracts and deliveries made before the war.

The hearing was adjourned.

Method Used in Driving the Rogers Pass Tunnel*

The 5-mi. tunnel of the Canadian Pacific Ry. at the Rogers Pass summit of the Rocky Mountains (having its east portal 80.5 mi. west of Field, B. C.) will be the longest tunnel on this continent, and will be large enough for a double track.

The tunnel will be 26,400 ft. long between portals, on tangent, and will have a grade of 0.95% throughout. In section it will be 29 ft. wide at rail level, with vertical sides and semicircular roof. The height will be 21½ ft. from base of rail to crown, or 23 ft. above subgrade. Construction was commenced in September, 1913, and the contract calls for completion within 3½ yr. (by Dec. 3, 1916). This necessitates rapid and steady progress, and for this purpose a novel method of driving the tunnel was devised by the contractors and approved by the railway company's engineers.

Two Pioneer Side Tunnels Employed

To drive this long tunnel from the two ends only would have involved a protracted period of construction, and in order to expedite the work it was highly desirable to attack it at various points by means of intermediate headings. Shafts as used for tunnels at moderate depths were out of the question for this great Rocky Mountain tunnel. Nor were there opportunities for the use of adits such as have been employed in exceptional cases of side-hill tunnels.

The method devised was to drive from each end a pioneer tunnel or drift, parallel with the main tunnel, but about 50 ft. distant from it. From these two drifts lateral drifts or crosscuts are driven to the center line of the tunnel at intervals of 1,400 to 3,000 ft. From each of these points the main tunnel heading is driven, working usually in the upgrade direction. This method gives numerous points of attack on the main tunnel. The drifts serve for the removal of material by cars, the ventilation of the headings and the placing of pipes and cables clear of the tunnel construction work. The two pioneer drifts, however, are on opposite sides of the line of the tunnel, the drift at the east end being on the north side and that at the west end on the south side of the tunnel. Thus they cannot be extended to form a continuous pass-

*Excerpt from "Engineering News," Nov. 11, 1915.

age, and each drift will be somewhat shorter than the half length of the tunnel.

These drifts and crosscuts were intended simply to facilitate the work on the tunnel, and their construction is entirely at the contractors' expense. It was not intended to use them permanently.

The nearest approach to a previous use of this system in driving long tunnels was in the construction of the first Simplon Tunnel in Switzerland.

The pioneer drifts and crosscuts are of rectangular section, 8 ft. wide and 6 ft. 6 in. high. The main or central heading, also rectangular, is 11 ft. wide and 9 ft. high. Working from each portal, this main drift is being enlarged to the full tunnel section.

Driving the Drifts and Headings

To save time and excavation the pioneer drifts were started considerably above the grade of the tunnel heading. The drift at the east end starts about 50 ft. above grade and is practically level, so that the first two crosscuts slope down to reach the main heading.

In driving the pioneer drifts at the east end four Leyner drills are mounted on a bar. These put in about 24 holes 6 ft. deep, 1¼-in. top and 1⅛-in. bottom diameter. Each hole is loaded with from 4 to 8 lb. of 50% dynamite. Similar drills are used in the center bench, drilling rounds of 26 holes 6 ft. apart, or 225 lin.ft. per round. These sections or "rings" are shot off for muck as required.

For ventilating the faces of the pioneer drift and advance heading two exhaust fans of the Connersville type (with 12-in. wood-stave pipe) are used, placed usually near a crosscut. From this point the exhaust pipe is carried to within 25 ft. of each face. A gate is provided so that the fan can exhaust from either face as required. Only one of these fans is worked at a time, so that one can be moved while the other is in service. The fan is started at each blast, and the men can return to work in from 15 to 25 min. By opening the 1½-in. air line for the drills the smoke and fumes can be cleared away from the face so that they will be removed by the exhaust.

At the portal of each pioneer drift there has been installed a multivane fan 5 ft. in diameter, which forces air into the drift. This air is diverted into the main tunnel whenever required. For instance, after shooting in the enlargement to full tunnel section the air is turned in at a cross-drift beyond the point of shooting. In this way the smoke and gases are cleared out of the tunnel very rapidly.

Working Force and Staff

The force per 8-hr. shift in the pioneer drift is as follows: Four drillers (4 drills at each end), 2 helpers, 8 to 10 muckers, 1 nipper, 1 driver, 1 shift boss, 1 to 4 mules and about 40 cars.

The force per 8-hr. shift in the advance heading of the main tunnel is as follows: Three drillers (3 drills at each end), 2 helpers, 8 to 10 muckers, 1 nipper, 1 driver, 1 shift boss, 1 mule, and 60 to 80 cars (according to the length of haul). In addition, there is the following force on each 10-hr. shift to cover the two small drifts in each end: One assistant superintendent, 1 walking boss, 2 blacksmiths, 2 blacksmith helpers, 12 laborers, 10 dump men, 6 teamsters, 14 mules, 1 hoistman and 2 pipe-fitters, carpenters, mechanics, etc.

The center bench of the main tunnel is worked in 8-hr. shifts with 2 to 10 drills, 2 to 10 helpers, 5 to 10 muckers, 1 shifter, 1 driver and 1 mule.

The completion of the main tunnel to full section is worked in 10-hr. shifts, with the following force per shift: One driller, 1 helper, 1 to 2 powdermen, 1 engineman and 1 craneman on the mucking shovel, 10 to 12 pit men at the shovel, 1 general foreman, 1 foreman and 12 to 15 laborers for the dump and track work, 2 compressed-air dinkey locomotives with 2 enginemen and 2 brakemen, 1 steam locomotive and 1 engineman, 1 fireman, 1 conductor and 2 car-repair men.

The contractors for the tunnel are Foley Bros., Welch & Stuart, of Winnipeg, and A. C. Dennis is the superintendent. The work is under the direction of John G. Sullivan, chief engineer, Canadian Pacific Ry., and W. A. James, engineer of construction.

The Explosion at Granite Mountain Shaft*

The explosion of 650 lb. of dynamite, which was loaded on a car and was about to be lowered down the Granite Mountain shaft of the North Butte Mining Co., caused the greatest loss of life that has resulted from any accident that has occurred in the history of Butte mining operations. This was due, mainly, to the fact that the explosion occurred shortly after 1 o'clock in the afternoon, when the shift bosses and nippers were waiting near the shaft to be lowered for the afternoon's work. Sixteen men were killed and four were injured.

Owing to the fact that all those who were near enough to the powder to have had any knowledge of the cause of the explosion were killed, any attempt to fix this cause is limited to pure conjecture. Among the many theories that have been advanced is the one that the powder may have been exploded by a rock falling from the headframe and striking it. However, the facts that the car was standing 25 ft. away from the collar of the shaft and that no skips containing ore or waste were at the top do not seem to support this theory. Experiments made after the accident also failed to indicate any such possibility. A stone approximately 8x4-in. in size, dropped from a height of 75 ft. onto a powder box filled with sawdust, caused only a slight indentation of the wood.

The explanation that now seems most plausible is that the car was struck by a stray rifle bullet fired by a person at considerable distance from the scene of the accident. The collar of the shaft is situated on an elevation at some height above the rest of the ground in the immediate vicinity, and it would therefore have been possible for a bullet coming from nearly any direction to strike the car. Boys are notoriously careless in handling guns, and unfortunately they and their guns are too common in the district.—The *Anode*, November, 1915.

The Largest Plate Mill in the World has been ordered for the Lukens Iron and Steel Co. at Coatesville, Penn. The exact length has not yet been determined, but it will be either 200 or 204 in. This compares with a 178-in. mill at Witkowitz, in Austria-Hungary, a 178-in. mill just ordered for the Imperial Steel Works of Japan, and a 168-in., two-high, reversing mill at the Dalzell works near Glasgow, Scotland. The Lukens mill will be four-high and provided with chilled working rolls 34 in. in diameter, supported both at the top and bottom by steel rolls 50 in. in diameter.

Natural Gas—Its Occurrence and Properties

By Dorsey Hager*

SYNOPSIS—*A résumé of the geologic and commercial factors in the development of natural-gas deposits. Further development of the American fields is urged.*

Natural gas is of course any gas formed in nature, such as marsh gas, sulphur dioxide, carbon dioxide (the "choke-damp" of the mines), sulphureted hydrogen and petroleum gas. However, as generally understood, natural gas is that obtained from oil or gas fields, and burned in our homes and factories instead of gases manufactured from coal or from petroleum.

The geology of natural-gas formations is now well understood. The chances for the occurrence of commercial natural gas in many untouched areas are so favorable, the efficiency and cheapness of natural gas are so much greater than other fuels, that I have wondered at the relative lack of interest of manufacturers in the possibilities of employing such a cheap fuel; and also at the lack of comprehension by gas men of the value of geology as applied to prospecting for natural gas.

Geographic Distribution in the United States

At present the chief productive natural-gas areas of the United States are in Kansas, Oklahoma, Louisiana, Pennsylvania, West Virginia and California. The Oklahoma and Kansas natural-gas deposits have been touched,

ANALYSES OF NATURAL GAS

Sample—Where Taken	Methane, CH_4	Ethane, C_2H_6	Carbon Dioxide, CO_2	Nitrogen, N_2	Hydrogen, H	Other Hydrocarbons	Helium, He	B.t.u. per Cu.Ft.

5 Dexter, Kan. . .	14 85	0 41		82 7		.	1.84	Noncombustible

Gases 2 and 3 are dry gases. Gas No. 4 is "wet" or casing-head gas. [Gas No. 5 is peculiar in that it contains 82.7% of nitrogen and 1.84% helium.

but have not been developed as fully as the oil resources. Illinois, Indiana, Ohio, Kentucky, New York, Tennessee, Alabama, Texas, Wyoming, Montana, Utah and New Mexico also have small gas fields. Alabama, southern Tennessee, eastern Mississippi, Iowa, Missouri, and Arkansas have gas possibilities that should be developed.

Natural gas is composed principally of the hydrocarbons methane (CH_4, commonly called marsh gas) and ethane (C_2H_6). Two elements, carbon and hydrogen, are the chief constituents of all natural gas. The analyses of one exceptional and of four typical gases are presented in the accompanying table.

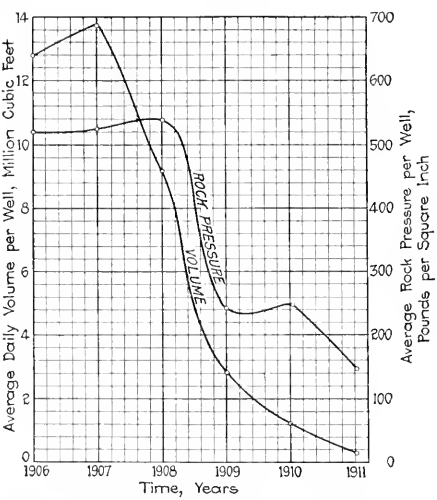
Origin of Natural Gas Uncertain

The origin of natural gas is shrouded in mystery. It may be of organic or inorganic origin—that is, formed by the decomposition of animal or vegetable matter—or it may be the result of the interaction of certain chemicals lying at great depths underground. Marsh gas is certainly due to decaying vegetable and animal matter, and it is not improbable that the natural gas from petroleum is also of the same origin.

Methane is the most stable of the hydrocarbons. It is highly probable that the heat breaks up the more complex hydrocarbons to form methane, so that gas is being continually formed in the earth wherever petroleum is found. It is not at all improbable that tremendous quantities of gas are formed in the change of lignite to bituminous coal and of bituminous coal to anthracite.

However, speculations along such lines lead to endless controversy, and for all practical purposes it is sufficient to note the occurrences of natural gas, and its economic importance, leaving speculations as to its origin to the ultra-scientists.

It is interesting to note that gas generally occurs in regions where lignitiferous, bituminous or petroliferous shales are found. The gas is generally found above the



DECLINE IN VOLUME AND ROCK PRESSURE OF WELLS IN THE CANEY FIELD—AFTER BLATCHLEY

Ascent of the curves is caused by new wells being added to the field during intermediate years

shales or in porous sand lenses interbedded in the shales. The relation of commercial accumulations of natural gas to shales is important, as one would not care to locate a well in regions where shales carrying organic matter are absent.

Some commercial gas has occurred in glacial drifts in Iowa, Illinois and Kansas. The gas was in all likelihood marsh gas resulting from the decay of vegetation buried at shallow depths. It may also be possible to utilize the marsh gas formed in the Gulf Coast regions, where, if collected above ground, it would in some places have a distinct commercial value as fuel for houses. Tremen-

*Petroleum geologist and engineer, Hotel Tulsa Building, Tulsa, Okla.

dous quantities of decaying vegetation occur in the coastal plains, and the utilization of the marsh gas given off by that vegetation is only a question of time.

Natural gas occurs in formations of the most recent to those of the early Paleozoic, Ordovician and Silurian ages. In fact, gas seems to be found wherever decaying vegetation or animal matter has occurred. The presence of natural gas in the older beds presupposes earlier vegetable or animal life, unless the gas has migrated from younger beds. Commercial accumulations are, however, dependent upon the trapping of the gas.

Factors Affecting Commercial Deposits

Commercial deposits of natural gas are dependent upon two essentials—a source of supply for the gas, and proper reservoirs. The source of supply has been treated under origin, and the reservoirs will now be considered.

It has been ascertained by careful observation and study that most productive natural-gas fields occur in beds that have been folded into arch-like structures called domes, anticlines (see Fig. 1), or some modification of those structures, as terraces, noses or monoclines. Lensed conditions also tend to accumulations. (See Fig. 2.)

An arch-like structure, such as that in Fig. 1, is called an anticline. Under ideal conditions the gas accumulates at the top of the fold; oil, if present in the same sand, lies below the gas, and water below the oil, in the order of the specific gravities.

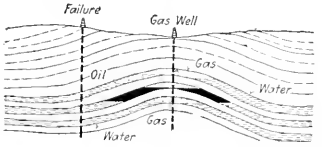


Fig. 1.

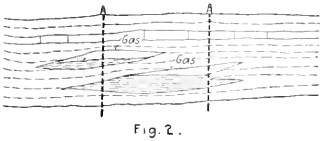

Fig. 2.

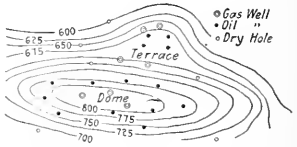

Fig. 3.

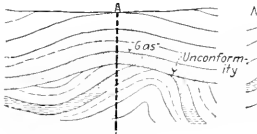

Fig. 4.

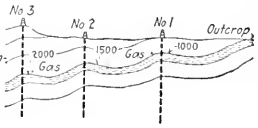

Fig. 5.

FIGS. 1 TO 5. DIFFERENT CONDITIONS OF NATURAL-GAS OCCURRENCE

The foregoing is the ideal case. In many instances gas is found above or below the oil sands. Where it is found in an oil sand, the oil and gas are quite often so closely associated that the gas may be said to be held in compression in the oil. Fig. 3 shows an anticlinal or domed condition, with a terrace upon its flank. Gas occurs at the top of the fold and also, as will be noticed, where the dip changes so markedly, both above and below the terrace.

Any sudden break or change in the dip tends to cause an accumulation of gas. Porous rocks, sands, sandstones, limestones or fractured shales form good reservoirs for gas if they are overlain and underlain by relatively impervious beds of sandstone, limestone or shale. The covering and underlying beds must be such that gas cannot escape through them and be dissipated into the air. Where the beds carrying the gas are "tight," or closely cemented, accumulations at the tops of folds will not be very productive. The more porous the reservoir, the greater the volume of gas it can hold, and cementation closes the pore space. Where the structures were faulted or broken so that vents to the surface were opened, gas escaped from the beds.

In some cases the gas has, in all probability, migrated from lower beds to higher, owing to unconformities (see Fig. 4) or to faulting. Gas naturally travels wherever an opening is afforded and only comes to rest where there is a relatively impervious covering to prevent its escape. The covering may be a compact limestone, dense shale or closely cemented sandstone.

Gas generally occurs with oil, but there are many productive gas sands that do not carry oil. These are called "dry" gas sands, to distinguish them from the gases carrying petroleum vapors. Gas sands occur above or below oil sands (see Fig. 1); also in districts where no commercial oil sands are obtained.

Variations in Pressure

The pressures of gas vary in different fields and for different depths of gas sands. There is, however, a remarkably close relation between the gas pressures and the depths of the gas sands. Especially is this true in the Mid-Continental oil and gas fields and in West Virginia. A well (see Fig. 5) 1,000 ft. deep will have a gas pressure of 400 lb.; one 1,500 ft., 600 lb.; one 2,000 ft., 800 lb.; or approximately 40 lb. per 100 ft. A study of a large number of wells shows that the pressure is approximately equivalent to the pressure exerted by a water column the height of the well.

Allowance should be made for the differences in specific gravities of the water and for the differences in elevations between the surface water table and the elevations at the collars of the wells. A column of fresh water 1 ft. high and 1 in. square exerts a pressure of 0.434 lb. per sq.in. Underground waters in the oil and gas fields have specific gravities of 1 to 1.3, which would make the water much heavier. In calculating, however, one can disregard specific gravities and simply use 0.4 lb.; this lower figure allows sufficiently for the loss in theoretical head resulting from friction, differences in elevation of the water table, etc. A difference of elevation of 100 ft. between wells means 40 lb. difference in pressure.

Allowing for such irregularities the pressures are remarkably consistent; so much so that in regions like Oklahoma and Kansas the gas companies base their estimates of pressures and also figure the weight of fittings necessary to control the well upon this important relation.

For example, fittings for a well 1,000 deep need to withstand only 400-lb. pressure. A factor of safety of 2 gives 800 lb. Such fittings will, however, be unsafe with wells 3,000 ft. deep, where there is a pressure of $300 \times .40 = 1{,}200$ lb. per sq.in.

The point is raised that if water is holding in the gas, the water should replace the gas when the gas pressure is weakened. Such, in fact, is generally the case. The gas is withdrawn very rapidly. The water moves more

slowly through the pore spaces of the sand, owing to friction and adhesion, with the result that the gas pressures are reduced for a short time. By shutting in a well, however, the gas pressure rises again, showing that hydraulic pressure is back of it.

There is considerable question as to the cause of the pressure, but there is no doubt that the hydraulic theory holds with but few exceptions. There is such a close relation between the head of water and the gas pressure that I do not feel inclined to disregard the artesian theory, especially for sands which are exposed to meteoric waters. I fully realize that artesian conditions do not apply in all places. At Fort Smith, Ark., little or no water is found in the gas sand. Pressures of but 145 to 280 lb. per sq.in. instead of 400 to 800 lb., are obtained at depths of 1,000 to 2,000 ft. The sands, however, are nearly free of water.[1] The synclines carry gas in that field.

Maximum gas pressures of 1,260 lb. are reported[2] at Midway, Calif.; 1,500 to 1,700 lb. are reported[3] in Green County, Penn.

Calculating Gas Volumes

A few calculations will give some estimate of the capacity of rocks to hold gas; also the large acreage that must necessarily be drained by gas wells. We will assume as a unit, a sand 1 ft. thick, containing 10% of voids or pore space per cubic foot, and covering one acre. An acre-foot, or 43,560 ft. of sand, under the conditions cited contains $43{,}560 \times 0.10 = 4{,}356$ cu.ft. of pore space. If this space be filled with gas at atmospheric pressure it will contain 4,356 cu.ft. The specific gravity of gas compared to air varies from 0.5529 for methane, to nearly 1, the specific gravity of air. The higher the quantity of ethane and the more complex hydrocarbons, the higher the specific gravity. An average specific gravity of 0.6 is generally assumed.

Gas volumes are measured at an average mean atmospheric pressure of 14.4 lb. per sq.in. and at a pressure of 4 oz. (0.25 lb.) above the mean atmospheric pressure. The pressure approximately corresponds to 14.7 lb. at 60 deg. F., the pressure at mean sea level. Theoretically, the temperature at depth should be taken into account, but in an approximate calculation such refinements are of little value. The number of expansions for 100-lb. "rock" pressure would be $\frac{100 + 14.7}{14.7} = 7.8$. The total volume per acre-foot will be volume of gas times expansions, or $4{,}356 \times 7.8 = 33{,}976$ cu.ft. per rock pressure of 100 lb. At 500-lb. rock pressure the expansions are 35 and the volume per acre-foot equals $4{,}356 \times 35 = 152{,}460$ cu.ft. At 1,000-lb. pressure the expansions are $\frac{1{,}000 + 14.7}{14.7} = 69+$, instead of 78.0 as one would at first imagine, the added 14.7 lb. becoming of less consequence the higher the rock pressure becomes. The volume will be $4{,}356 \times 69 = 300{,}582$ cu.ft. per acre-foot.

Gas has such mobility that one gas well situated at the top of a dome should in time drain all the gas from the sand. Good practice, however, allows 100 acres of land per gas well. One well per 40 acres is the minimum of good practice. Allowing one well to drain 100 acres, a well, under the conditions given, would take care of 152,460,000 cu.ft., for a pressure of 500 lb. and a sand 10 ft. thick.

A single well often produces many times the theoretical amount. It is more than likely that petroleum acts as a solvent for the gas and holds tremendous volumes in solution, as the hydraulic pressures set up are not sufficient to liquefy the gas. As several wild gas wells have produced from 30,000,000 to 70,000,000 cu.ft. per day and kept it up for months, it is a matter of wonder as to where the gas came from.

The graphic chart[4] (Fig. 6) gives some idea of gas volumes in producing fields. This was taken at the famous Caney, Kan., gas field and shows the life of that remarkable field. The high average volume of 10,694,000 cu.ft. per well, with the rock pressure of 490 lb. per sq.in. shows that such wells must have drained a large area. The total volume of gas over a period of five years would be $10{,}694{,}000 \times 1.825 = 19{,}516{,}550{,}000$ cu.ft. If the value of such gas at the well is $0.05 per 1,000 ft., the total value is $19{,}516{,}550 \times 0.05 = \$975{,}827.50$ per well. As such a well should not cost over $5,000 to drill, one should obtain extraordinary returns on the money invested. Pipe lines are expensive, however, the leakage is large, royalties and overhead expenses are to be considered, and depreciation is rapid. While there are large profits in the natural-gas industry, the profits are none too large for the risks taken.

Heating Value of Natural Gas and Other Fuels

The value of natural gas in heating is approximately 1,000 B.t.u. per cu.ft. The higher the percentage of hydrocarbon gases, such as ethane, the higher the number of heat units. This is clearly shown in the analyses already given. Comparison with coal, petroleum, wood and producer gas is presented in another table.

COMPARISON OF NATURAL GAS AND OTHER FUELS

Fuel	B.t.u.	Equivalent in B.t.u. of 1,000,000 Cu.Ft. of Natural Gas	Value
Natural gas, per cu.ft.	1,000	1,000,000 cu.ft.	At 10c. per 1,000 cu.ft. $100.
Oil gas, per cu.ft.	850	1,176,470 cu.ft.	At 25c. per 1,000 cu.ft., $294.
Producer gas, per cu.ft.	200	5,000,000 cu.ft.	At 5c. per 1,000 cu.ft., $250.
Petroleum, 14° Bé	18,500	160 bbls.	At $1 per bbl., $160.
Coal (bituminous), per lb	12,500	40 tons	At $2.50 per ton, $100.
Wood, per lb	5,000	66.6 cords (1 cd. 3,000 lb.)	At $3.50 per cord, $198

However, B.t.u. do not measure the true efficiency of gas. The efficiency of combustion of gas is greater than that of other fuels, so the actual efficiency will be 10 to 20% greater.

The development of the casing-head gasoline industry has sprung into prominence within the last five years. It has been found that gas coming directly off petroleum carries hydrocarbon vapors that can be condensed by pressure. These vapors consist of the lighter hydrocarbons that go to make up naphthas, benzine, gasoline, etc., having specific gravities of 70 to 100°. A rich gas may carry 5 gal. of gasoline per 1,000 cu.ft., but 1 gal. per 1,000 cu.ft. can be made to pay if a sufficiently large quantity of gas is obtained. The gasoline is first extracted, and the "dry" gas is introduced in the gas line for fuel.

High Wages and Steady Work a Cure for Butte Socialism

SPECIAL CORRESPONDENCE

The great improvement in conditions in the Butte mining district in the past year called forth from the mayor of the city, Charles H. Lane, a special Thanksgiving proclamation in which he calls attention to the facts that at present Butte has the largest number of men working in its mines ever known and that the payrolls are the largest, the community the most contented and happy and the reasons for thankfulness greater than ever before.

The improvement in labor conditions in the past year has been marked. It is just a year since the Anaconda and other large mining companies announced their intention of employing men without regard to their labor-union affiliations. The companies took the position that the men might belong to any union they chose or no union at all, but the question would not be raised or recognized. At the same time the companies made the pledge that labor conditions would not be allowed to become worse under the open-shop system than under the old one and pledged themselves to adhere to the union scale in effect.

They have carried out this promise with the result that the high price of copper makes the Butte wage scale today $4 per day of 8 hr. for every man in the mines, as against $3.50 that was being paid under the old régime. The men are well satisfied, and the efforts of foreign agitators to gain a foothold here have met with no success.

Socialism, which was so powerful that it held the reins of city government for four years and came near to getting control of the county government, is dying out, and while the socialists still maintain their organization, they have few members compared with former times. High wages and steady work for all have proved a good remedy for socialism.

Butte miners and mining companies are watching with interest for the completion of the improvements at the Washoe and Great Falls smelteries, as they anticipate that there will be a large increase then in the amount of ore handled from the mines of Butte. This will mean quite an addition to the force of men employed here, and the prediction is freely made that Butte's mine payrolls will comprise 20,000 names before the end of the winter.

Mount Lyell Mining and Ry. Co.

Announcement was made some time ago of the new rich ore encountered in the properties of the Mount Lyell Mining and Railway Co., Ltd. The recent report for the half-year ended Sept. 30, 1915, states that prospecting work has disclosed considerable additions to the South orebody and large accessions to reserves in No. 40 and No. 41 stopes in the North Mount Lyell mine, which continued to yield high-grade ore. The crosscut at the 1,200-ft. level of the North Mount Lyell mine was driven 54 ft. through rich ore, which is still in the face.

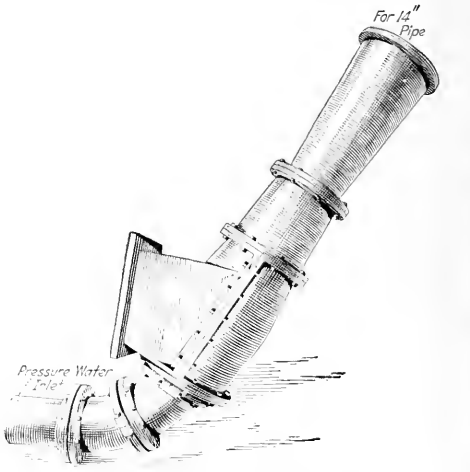
The ore reserves of the Mount Lyell mine were given as 1,791,479 tons; North Mount Lyell mine, 973,210 tons, not including important additions disclosed by development work. The cost of producing blister copper for the half-year was 18s. 7d. ($4.52) per ton of ore. During this period 1,053 tons of blister copper was produced. The net profits were £139,071, after writing off £20,123 for depreciation, £14,656 for prospecting and development work, and £18,500 for Federal and state income taxes. The saving from the full use of the Lake Margaret power installation was partly offset by the greater consumption of coke and the increased cost of supplies.

The flotation plant is being erected and is expected to start work during the current half-year. Options have been acquired on some West Coast mines owned by the Hercules Gold and Silver Mining Co., the Primrose Mining Co. and the Tasmanian Copper Co. Flotation tests of these ores on a commercial scale have been arranged for at Broken Hill.

Hydraulic Mining at Circle

BY HUBERT I. ELLIS*

In the *Journal* of Dec. 19, 1914, there appeared a short article, "Hydraulic Mining at Circle," describing the operations of Theron E. Fell on Mastodon Creek, Circle district, Alaska. Through the courtesy of Mr. Fell I have recently obtained additional data, which are given here.



SKETCH OF HYDRAULIC ELEVATOR

The Mastodon Creek ground is tight, contains much clay and many comparatively large rocks, and is difficult to work by pick-and-shovel methods. The cost of hydraulicking with water under a head of 100 ft. averages about 25c. per cu.yd. When using a 175-ft. head the plant washes 500 cu.yd. of material per day at a cost of 17c. per cu.yd. All giants except the one used in the tailings are of the No. 1 size, having a nozzle orifice of 2 in. The tailings giant is a No. 2, with a 3-in. orifice.

The general layout of the plant is illustrated in Fig. 1. The giants and boxes are first set as shown by the full lines. A sort of wing-dam is built, baffle boards are put on the boxes, and the gravel is driven into the boxes from one side. When this side of the cut is clear the large rocks are wheeled forward to provide drainage for the cut. The

*Kellogg, Idaho.

boards are then changed, and the other side is cleaned. This leaves only a ridge of gravel under the boxes when the cut has been finished, and this is blown upstream to the ground in the next cut. Bedrock is washed clean upstream with the tailings giant after the boxes have been removed. When all the material possible has been blown into the boxes from the first setting and bedrock has been

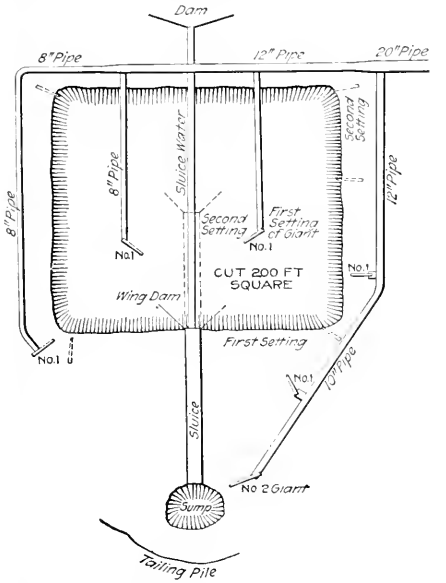


FIG. 1. PLAN OF FALL, HYDRAULIC MINE

cleaned, new boxes are added to the upper end of the string and the giants are reset in the positions shown by the dotted lines.

Some difficulty has been experienced in disposing of the tailings. At first an inclined chute and a No. 2 giant were used at the dump, but where the gravel contains but little sand the tailings are now simply blown up into a pile with the giant.

The chute method, *A* and *B*, Fig. 2, is illustrated. The chute is 4 ft. wide and has 3-ft. sides. The bottom is

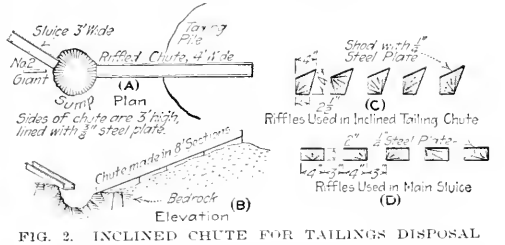

FIG. 2. INCLINED CHUTE FOR TAILINGS DISPOSAL

fitted with beveled steel-shod riffles, shown at *C*, set at an angle that will keep the gravel from rolling back into the sump. This method is better than the other when the gravel contains a considerable proportion of fine sand and pebbles that the water will carry away. It also serves to keep the water from washing back small rocks that have been blown up out of the sump.

The proportions of a tailing pile are shown in Fig. 3. This is made by simply blowing the gravel up with the giant working under a 100-ft. head, no chute of any kind being employed. Experience has shown that the tailings can be stacked in this manner to a height equal to

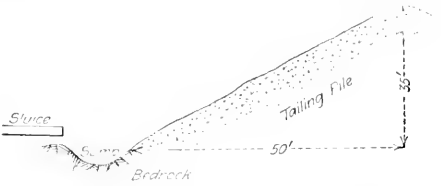

FIG. 3. SECTION OF "BLOWN-UP" TAILINGS PILE

one-third of the head on the giant at a distance from the sump equal to one-half the head. There is no difficulty in handling rocks half the size of a kerosene can by this method, and it is much more economical of water than the hydraulic elevator and more efficient for some classes of material than the inclined chute.

Butte & Superior Report

The Butte & Superior Copper Co., Ltd., reports results for the third quarter of 1915 as follows: Dry tons of ore milled, 130,210; average zinc contents, 17.147%; average silver contents, 1.6027 oz. per ton; zinc concentrates produced, 37,396 tons; average zinc in concentrates, 55.1219%; total zinc in concentrates, 41,230,885 lb.; average silver in zinc concentrates, 21.9646 oz. per ton; mill recovery (zinc recovered in concentrates), 92.3322%; mining costs per ton, $3.4584; milling costs per ton, $1.7652; total cost per ton, mining and milling, $5.2236.

The tonnage of ore treated was the largest of any quarter in the company's operations. In addition there was an increase of 2.8% in the recovery and an improvement of 2.1% in the grade of concentrates produced. The Black Rock shaft was continued to a depth of 1,559 ft., a station cut on the 1,500-ft. level and a skip pocket installed on the 1,600-ft. level. Preparations are being made to sink a new working shaft of greater capacity than the present one, designed to fulfill mining requirements to much greater depths than could be economically served with the present shaft. The new shaft will be entirely out of the orebody and, when completed, will release large bodies of ore adjacent to the present shaft, which cannot safely be mined during its use as a main ereway. Underground developments for the quarter were satisfactory in every way. Extensions of the orebody were disclosed in an easterly direction on all of the principal lower levels where work is now being conducted. No recalculation of ore reserves was made as applying to the third quarter, but it may be said that the new ore reserves developed were practically equivalent in quantity to the ore mined.

Financial results for the third quarter were as follows: Net value of zinc concentrates (at mill), $2,997,128; net value of lead concentrates (at mill) and of residues, $228,111; miscellaneous income, $14,716; total gross operating returns, $3,239,955; operating costs, $679,635; profits, $2,560,330, together with a further profit of $201,510 due to the excess received from the sale of con-

centrates and smeltery residues over the values at which these products were estimated in the monthly statements. At the end of the quarter and after payment of the dividend at that time, the company states that it had on hand approximately $5,000,000 in quick assets, consisting of cash and products conservatively valued in process of treatment and in transit.

Radium Extraction from Carnotite

Bulletin 104, "Extraction and Recovery of Radium, Uranium and Vanadium from Carnotite," by Charles Parsons, R. B. Moore, S. C. Lind and C. C. Schaefer, has just been issued by the Bureau of Mines. This Bulletin gives the results of the coöperative work with the National Radium Institute and describes the methods of extracting radium from carnotite ore as carried out in the plant at Denver.

The methods devised have proved highly successful. They depend essentially upon the fact that strong hot nitric acid has a high solubility coefficient for radium and barium sulphates. This enables the carnotite ores to be treated directly with hot nitric acid, removing the radium therefrom at a single operation. The method follows in brief:

The carnotite ore pulverized to 20-mesh is treated in an earthenware leaching pot with 38% nitric acid, 500 lb. of ore being used to 121 lb. of 100% HNO_3. The acid is brought near to boiling by means of steam passed through a glass tube and the ore gradually stirred in. Heating is continued for 15 min., when the acid is filtered from the ore in a stoneware filter. This is followed by a second treatment in the same leaching pot with somewhat weaker hot nitric acid, after which the whole is washed with hot water. Nearly all of the uranium, about 50% of the vanadium and over 90% of the radium are carried into solution by this method and separated from the bulky residues, which are then discarded. The acid solution is nearly neutralized with sodium hydroxide and barium chloride and sulphuric acid added in proper quantities and held in settling tanks with conical bottoms for three days to settle out the radium-barium sulphate. The supernatant liquid is then siphoned into an excess of boiling sodium-carbonate solution to separate the uranium and vanadium from iron, aluminum and calcium. The radium-barium sulphate left in the tank is run onto a stoneware filter, filtered, washed and dried, the washings being also added to the sodium-carbonate solution already mentioned.

The soluble sodium-uranyl carbonate and the sodium vanadate are filtered from the iron-calcium precipitate in filter presses and run into uranium-precipitation tanks. The sodium carbonate is then nearly neutralized with nitric acid and sodium hydroxide added to complete precipitation of the uranium as sodium uranate. The filtrate containing the vanadium is carefully neutralized with nitric acid and iron sulphate added to precipitate vanadium as iron vanadate. Both the sodium uranate and the iron vanadate are separated from their solutions by means of filter presses. The filtrate from the iron vanadate consists almost wholly of a solution of sodium nitrate containing, of course, a small amount of impurity. This filtrate is evaporated, sodium nitrate recovered and used again for the manufacture of nitric acid. The radium-barium sulphate, without further treatment, is reduced in large graphite crucibles by charcoal, a very efficient conversion (90 to 95%) into barium-radium sulphide being obtained. The sulphides are dissolved in hydrochloric acid and the residue of unchanged sulphates re-treated.

The chloride solutions are crystallized in the plant in silica-lined kettles, care being taken to keep the solutions acid with hydrochloric acid, as the separation of radium from barium is much more rapid under these conditions. The concentrated chlorides carrying from 4 to 10 mg. of radium per kg. are taken to the laboratory, filtered from any insoluble impurities and crystallized again in strong acid solution until the bulk has been reduced to a small volume, when they are converted into bromides. This is done after first neutralizing with ammonia and precipitating with hydrogen sulphide to remove lead, which always accumulates and which is not precipitated by hydrochloric acid from strong barium-chloride solutions. After removal of the lead, the barium and radium are converted into carbonates by the addition of ammonium carbonate, washed, and dissolved in hydrobromic acid. From this point on crystallization takes place in pure quartz dishes in solution strongly acid with hydrobromic acid.

The fractional crystallization of radium from the original chlorides to the finished product is neither tedious nor difficult, but takes place rapidly when acid solutions are used and proper apparatus is available which will withstand their action. The efficiency of the process is high.

In connection with the radium plant a nitric-acid plant has been erected which produces over 5,000 lb. of nitric acid per day. Owing to the recovery of sodium nitrate, the cost of the nitric acid used has been very low, averaging under the present cost for nitrate slightly less than 2½c. per lb. To Sept. 1, 4,774 mg. of radium was produced in the form of sulphates and 1,947.5 mg. of element had been delivered in the form of bromide. Deliveries are continuing at the rate of 300 to 400 mg. per month.

Flotation at Cripple Creek

Flotation will replace the cyanide process in the Independence plant, at Victor, Colo., according to a report published by the *Daily Mining and Financial Record*, Denver, Nov. 27, 1915. The plant is now being remodeled, and next week the company will commence the construction of a sampler of large capacity. This sampler will be for the low-grade ores exclusively and will not compete with the samplers now in operation in the district. The sampler will be run in conjunction with the mill, and all the rock will be passed through the sampler crushers direct to the chilean mills, where the final grinding for flotation treatment is accomplished. The chilean mills will be supplemented by ball mills which will reduce the ores to a degree of fineness not hitherto attained.

By the flotation process the company feels assured that it can successfully treat ores of a lower grade than has heretofore been possible. There are millions of tons of dump ore that can be successfully handled and in addition, the boon to the leasers and prospectors of the camp will be inestimable in that these men will be enabled

to sell their low-grade ores at a sufficient profit to pay at least a part of their expenses and thus be able to continue development work which may result in the opening up of better ores.

Arrangements have been made with the railroads for the hauling of the ores from all parts of the district, and surveys for tracks to the sampler have already been made. The Portland company has under consideration the provision of an adequate supply of 50-ton steel dump cars that will be unloaded automatically. Under this plan, from the time the rock is dumped from the cars until the tailings are run on the dump the progress of the ores through the mill will be automatic.

The mill will have an initial capacity of 1,000 tons a day, with the probability that a much larger tonnage will be reached eventually, provided the Portland company secures the coöperation that it has every reason to expect.

The problem of successfully handling the low-grade ores of the gold camp has always been recognized as one of prime importance, and it is now believed that the solution of the problem will be achieved by the flotation process, which represents the latest word in scientific treatment.

Gold Dredging in Philippines

The rapid increase in the gold production of the Philippines during the last few years has been noteworthy. In 1910 the gold output was valued at 308,860 pesos; in 1914 it was 2,349,267 pesos. Gold dredging has played a prominent part in this advance and is likely to be still more important, as additions are being made to the dredging fleet. According to the statistics just announced by Wallace E. Pratt, chief of the Division of Mines, the dredges were responsible last year for nearly 44% of the total gold output. Eight dredges were in operation, seven of which were in the Paracale-Mambulao district of Ambos Camarines and one was on the Umari River in Tayabas Province on the east coast of Luzon.

The Gumaos Placer Co. operated continuously throughout the year. Its dredge, built by the New York Engineering Co. and described in previous numbers of the Bureau of Science bulletin,[1] has achieved an enviable record during the period over which its operation extends. On an original investment of 500,000 pesos ($250,000), the company has paid in dividends during 27 months of operation the sum of 535,000 pesos, or 107%. The generally nonuniform character of the dredging ground in this district is exemplified in the record of the Gumaos dredge; the average value per cubic meter for different monthly runs varies from 6 centavos to 1.66 pesos. The average value for the whole period of operation has been 64 centavos per cubic meter. The cost of operation, according to the company's figures, is about 21 centavos per cubic meter dredged. The average fineness of the bullion smelted is 873. The depth of bedrock varies up to 17 m., but has averaged about 11 m. The gold recovered is fine and is very sharp and angular. It is confined to a layer of wash usually less than 2 m. thick immediately overlaying bedrock; the overburden is largely clay. . . . [The total gold recovered, to the end of 1914, by this dredge is valued at 912,205 pesos.]

[1] "The Mineral Resources of the Philippine Islands for the Year 1914," Division of Mines, Bureau of Science, Manila, P. I.

The Paracale Bucket Dredging Proprietary, Ltd., and the Philippine Dredges, Ltd., closely associated Australian corporations, had four dredges at work during 1914. One of these started in November, and another lost a great deal of time as a result of litigation over title to the ground upon which it was situated. In spite of obstacles, however, the year's record was good, and much credit is due William Telford, the general superintendent for the two companies.

The Malaguit Dredging Co. placed a new dredge on Malaguit River early in 1914. Some time was lost in getting into proper running order, but the dredge recovered a gratifying amount of gold and will undoubtedly do better as the operation becomes established.

The Philippine Dredging Syndicate and the Maximelo Dredging Co. each operated one dredge in 1914. About the middle of the year the former company finally dismantled its old Risdon dredge, which was built in Masbate in 1905, moved over to the Paracale district in 1908 and has been digging on Malaguit River since that time.

The Mambulao Placer Co. is reported to have obtained exceptionally high results from the tests of its dredging property at the head of Mambulao Bay, and a New York Engineering Co. dredge will be erected at Mambulao during the coming year.

Several dividends were declared by the dredging companies during the last year, and the industry appears to be in a healthy condition. The year 1915 should show a materially increased gold production. New dredges are under construction for some of the operating companies at Paracale, and the Mambulao Placer Co. will enter the dredging field, although it may not begin to produce until early in 1916.

Results at La Grange Improving

The operations of La Grange hydraulic mine in Trinity County, California, which has been in *borrasca* for several years, showed an improvement this year over the 1914 results despite the fact that the season was unfavorable climatically. In July the southern, or richest, part of the mountain became accessible, and by confining operations to this section, the company's engineers expect that henceforth profitable results will be obtained.

This year the water supply, which at the beginning of the season promised to be as large as that of any previous year, turned out to be less than for any season in the history of the company. This was due to breaks in the aqueduct, resulting from exceptionally heavy falls of snow and unusually cold weather in August. However, the mine paid its expenses though up to July 1 the richest part of the deposit had been inaccessible.

Chippewa Falls Power Development

BRAINERD CORRESPONDENCE

The Wisconsin-Minnesota Light and Power Co. has applied to the Railroad Commission of Wisconsin for permission to construct a dam across the Chippewa River above Chippewa Falls. The dam will develop a head of 60 ft. and provide 43,000 hp., and it will be the largest power-development plant in Wisconsin. The proposed construction involves an expenditure of upward of $2,000,000. The company is capitalized at $10,000,000.

Details of Practical Mining

Leyner versus Piston Drill

By L. P. Gordon

The accompanying table shows a comparison between Leyner and piston drills. These data were taken from accurate records of the opening of new sublevels in a mine of one of the large operators in the Iron River district. The drills operated under the same conditions, namely:

1. Ore extremely coarse, "fitchery" and hard, requiring one set of steels, and more at times, per hole.

2. Mounting—Upright double-jack post with arm and clamp.

3. Drifts, 6x7 ft.

4. Uniform air pressure and hoses according to size of air inlets in drills.

5. Broken ore handled by trammers on opposite shifts.

Type of Drill	Men Shifts	Labor Cost*	Drift Feet	Drill Shifts	Drift Feet per Drill Shift	Holes Drilled	Average Depth of Holes, Ft.	Feet Drilled	Feet Drilled per Drill Shift	Average Labor Cost per Drift Foot*	Average Earnings per Man per Shift
Leyner	448	$1299.20	906	224	4.05	3226	5	16,160	70	1.43	2.89
Piston	298	809.39	261	149	1.75	1139	5	5,695	38	3.10	2.71

*Includes rigging and blasting.

The Leyners were used to great advantage in stoping, particularly in drilling slice and upper holes, and they handled 12-ft. steel with ease in down or stope holes. A tripod with an adapter plate fitted in the saddle was used as a mounting in drilling on the benches.

Deterioration of Hoisting Ropes*

There may be said to be five ways in which deterioration of a rope proceeds: First, there is frictional wear; second, there is breakage of wires due to inequalities in even the best material; third, there is the breakage caused by the stress of bending over sheave and drum; fourth, there is corrosion inside and out; fifth, there is fatigue of the steel caused by its passing its elastic limit and accelerated by bending and by rapid hoisting. All of these effects finally take the form of broken wires. For this reason the appearance of broken wires is considered the best single sign to follow in deciding when to discard a rope.

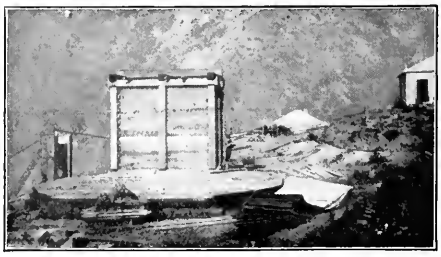
The manner in which breaks occur is of significance. Thus when a new rope is installed there is likely to be a short period, while the rope is taking its set and equalizing tension, during which breaks are relatively frequent. These breaks are of no importance and do not indicate that the rope is wearing out. After the period of their occurrence, the rope will run for some time without more wires breaking. Toward the end of the life of the rope, however, it may happen that the number of breaks begins to increase rapidly. Thus inspection on one day may show one wire broken at a certain point. The next day two may appear there and the third day, three or four. This condition arising is a sign that the rope is going to pieces and should be taken off forthwith. It may also happen that breaks occur before any great wear is visible—this, of course, after the period of initial breaking. Breakage without wear indicates faulty installation of some kind; either the rope is made of brittle wires or it is being bent over too small a drum or sheave.

*Abstract from Bulletin 75, U. S. Bureau of Mines.

A Wooden Ore Bin with Concrete Bottom

By C. M. Eye*

In order to avoid difficulties, encountered in the tropics, from rapid decay of wooden bottoms in ore bins, as well as to secure the maximum storage capacity, the bin shown in the cut was designed for the new 10-stamp mill of the Benguet Consolidated, at Antimok, Benguet, P. I. The base consists of a frame of 12x12



WOODEN ORE BIN WITH CONCRETE BOTTOM

timbers, rodded together, on which the 12x12 posts rest in daps, secured by steel pins 7/8x12-in. (Mortise-and-tenon joints were avoided on account of certainty of decay, due to water collecting in the mortises). All joints were well painted with asphalt paint, and base timbers were well tarred with hot coal tar.

Cross-timbers at the top are all 12x12, with two 12x16 timbers for the crusher. The bin is lined with 3x12 plank, all placed horizontally and cribbed at the corners. The bottom consists of 9 in. of rock, laid dry, with dry sand poured in and tamped, on which is laid 3 in. of concrete, bringing the floor level with the top of the base frame. The front of the bin rests on the retaining wall back of the stamps, with a 45° slope to the chutes to the feeders. The conformation of the site allowed placing the bin at a relatively greater height above, and distance from, the batteries, thus avoiding overhang and thrust. There are no connecting timbers between the bin and battery posts, the latter being braced by 12x16 timbers set in the retaining wall.

*Bagnio, P. I.

The inside dimensions of the bin as finished are: Width, 11 ft.; length, 14 ft.; height, 13 ft.; content, 2,000 cu.ft.; capacity, 100 tons, with broken ore at 20 cu.ft. per ton. The cut shows the structure as completed and the completed foundation platform for 25-ft. solution storage tank.

This bin is an exceedingly easy one to construct and secures the maximum of capacity with minimum of material.

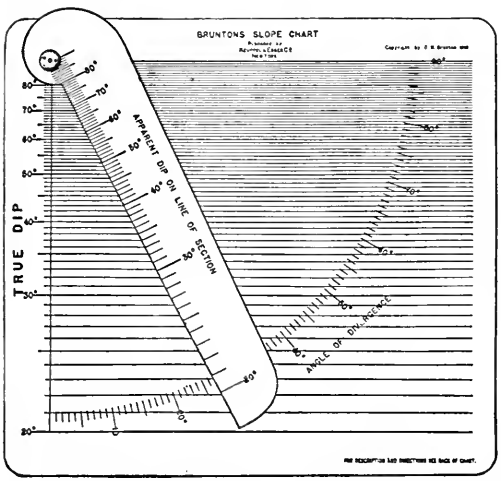
The Brunton Slope Chart

The Brunton slope chart is a device for the determination of the apparent angle of sections when cut at planes of varying degrees of divergence from the dip. The chart enables the user instantly to obtain the apparent dip from the true dip, or *vice versa;* mechanically solving the equation, *tan C = cos A tan B*, in which *C* is the apparent dip, *A* the angle of diversion, and *B* the true dip.



BRUNTON SLOPE CHART FOR SOLVING EQUATION TAN C = COS A TAN B

In addition to its utility in the preparation of maps and geological sections, the chart is also useful for giving the valley angles in hoppers, ore bins, etc. It is published by the Kenffel & Esser Co., Hoboken, N. J.

Underground Toilet Systems

Passed Assistant Surgeon A. J. Lanza of the Bureau of Mines in Technical Paper 105, on "Pulmonary Diseases Among Miners in the Joplin District, Missouri," gives the following regarding underground toilet systems (or lack of them) at small mines. It offers good suggestions on a troublesome subject.

There is no established toilet system underground in the Joplin district. Many of the mines are small, employing 25 or 30 men and less, and the necessity for the toilet systems seen in large mines does not exist. As in other mining districts, there is a strict rule against ground pollution in the mines, a rule that, as elsewhere, is not infrequently broken. In some of the mines visited there was much evidence of this abuse, and in spite of the efforts of operators and ground boss[es] are always, from time to time, infringements of th[is] It does not seem at present that there is any pres[sing] need of establishing toilet systems underground, thou[gh] they might prove useful in some of the large mines [in] the district. In the latter, one sanitary privy underground would be a convenience and tend to check ground pollution. Such a privy could be cheaply constructed having removable containers (empty powder boxes with a layer of sawdust within) that could be hauled to the surface daily and burned. This is a cleanly, cheap and efficient toilet system where only a small number of men are employed.

In this connection, comment on mine privies is not out of place. At most of the mines there are privies on the surface, within easy access of the shaft or the change house. Some of these are clean and well kept; others are not clean, are not well kept, are in disrepair and are a nuisance in every respect. Wretchedly insanitary privies are only too common everywhere in this district, and those seen at the mines were often no exception to this rule.

*

Some Safety-Fuse Pointers*

The most important part of safety fuse is the powder train, and unless it is in good condition, results are likely to be bad. The worst fault that fuse can have is to be without powder. High-grade automatic machinery is used for detecting lack of powder or serious reduction in quantity, and it is a rare occurrence to find fuse lacking the standard charge.

There are two kinds of powder core. One is called "free" and the other "solid." "Free core" is where the grains are free in the yarns that inclose them and should appear clean and distinct. The "solid core" is where the powder core is made into a semisolid mass, clinging to the center thread and adjacent yarns, so that when the fuse is opened the powder will not drop out freely as it does in "free-core" fuse.

In examining fuse to see whether the powder core is injured, it is necessary to give consideration to the next most important feature of a good fuse, namely, the waterproof covering. These coverings are made of compounds of asphaltum, tar, etc., as well as gutta-percha. If improper materials are used, the compounds may penetrate through the yarns to the powder, and this will give it a dingy and somewhat sticky appearance, and may be so bad as to ruin it. Powder that is wet will be soft and dingy black in color, but usually it will harden into grayish lump particles after it has been dried. When the moisture has entered from the outside, the white exterior color is usually left in a lusterless, chalky condition.

Fuse may become injured in transit, storage or handling, and it is important that it be stored in a cool, dry place. Fuse stored in too warm a place is liable to be affected by the melting of the waterproofing material and their penetration to the powder. Fuse should be warmed to a temperature from 60° F. to 70° F. before uncoiling, because in cold weather the waterproof material becomes brittle and will crack unless the fuse is carefully handled. Moisture kills the powder, and ever

*From the "Du Pont Magazine."

when insufficient actually to kill it, its presence retards the burning speed. While the waterproofing covering may protect the interior of the coils, the ends absorb sufficient dampness to kill the powder, or at least make it difficult to light.

When fuse is so stiff and brittle as to break open in being handled, its water-resisting qualities are impaired. If fuse is allowed to become too old before it is used, there is danger that the varnishes will be dry and hard or that the powder may have become impaired by age, although such results are not likely to occur for several months if the fuse is properly stored. Gutta-percha fuses are the most subject to deterioration for the reason that gutta-percha, rubber and other vegetable matter of this nature are subject to oxidation from contact with air.

The uniformity of burning speed is a desirable quality, but fuse that burns in the open air with a maximum variation of 10% up or down from standard is within reasonable limits. The generally accepted standard is 90 sec. per yd., or 25 min. per 50 ft. This is fast enough to preserve a fair degree of regularity and slow enough to produce quiet burning.

The exterior appearance of the fuse has become of considerable importance. If the fuse is of extremely dingy appearance, it may be most excellent in quality, while on the other hand the reverse has been proved. Some kinds of waterproofing will absorb the white material put on the outside when subjected to the heat of summer, causing it to appear black or of a dingy yellow color. Either bad storage or transportation conditions, particularly too much heat, turn the outside of the fuse dark. This gives it an unfavorable appearance, but a test should be made and this will easily determine its condition.

An absent center thread will not alter the burning speed of fuse. Its purpose is merely to make certain the powder flow in the fuse machine, and if the powder is present in proper quantities the center thread is unnecessary. The size of the powder core does not in itself alter the burning speed. The properties of the powder and the mechanical and constructional effects employed govern this.

In tape fuse, places may be found where the diameter is slightly enlarged for about an inch in length. These are caused by the overlapping of the ends of the tape where two pieces are sewed together to make a continuous length. They are perfectly harmless.

Cut off about 2 in. from each end of the coil before using to be sure that the ends are dry, as the powder may have absorbed moisture from the air. For this same reason it is unwise to cut up the fuse lengths much ahead of actual need unless they are stored in a dry place. Cut off the ends of the fuse squarely, especially where they are to be inserted in a blasting cap. One cut diagonally is apt to fold over and interfere with the spit. For wet holes, the joint of the cap should be made waterproof by an application of P. & B. paint, heavy axle grease[1] or Kapseal.

In tamping use a wooden tamping bar and a stemming material that is free from sharp bits of rock or anything that will cut the fuse. Be careful not to kink or double it over in the holes.

[1]The Coast Manufacturing and Supply Co., manufacturer of much of the fuse that is used in the Butte mines, has published a pamphlet which contains the following: "Grease and oil, being solvents of the fuse varnishes, destroy the powder train in the fuse with as great, if not greater, rapidity than would the water which the miner is trying to exclude."—Editor.

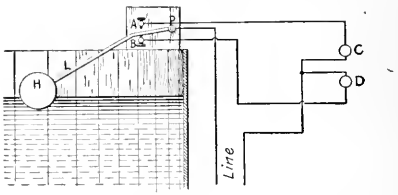
The kind of stemming material used is important because considerable gas is generated by burning fuse, and if it is too closely confined by a material that is not porous, the pressure of the gases rises to such an extent that the speed of burning is much affected. Usually the speed is increased as the pressure rises. In experiments made of moist fireclay as a stemming material, the rate of burning of the fuse was increased over 50%; but with dry sand, moist sand, and dry fireclay, the increase in the burning rate was comparatively small.

Signal for Water-Supply Tank*

Now that cold weather is once more with us every power-house engineer who has to look after a water tank placed on a hill to supply water to the town knows how unpleasant it is to go out of a warm engine room to find out how much water he has in the tank. Many such engineers let the pump run most of the time at full speed, in which case it generally happens that the tank overflows.

This is a waste of power, for at a small cost a signal system may be installed that would take care of the water-supply. Such a system is shown in the accompanying sketch. It is designed to work on either a 110- or 220-volt circuit; however, should only 550 volts be available, two 250-volt lamps in series at *C* and two at *D* would be all the changes necessary. *H* is a hollow ball, which may be made of copper or of cork.

This ball is fastened at the end of level *L*, which is pivoted at *P*, its rise or fall completing the circuit of *C*



SIGNAL FOR WATER-SUPPLY TANK

and *D*. If rising, *L* makes contact with the adjustable screw *A* and will light lamp *C*; if falling, it makes contact with *B* and lights the lamp *B*. The latter lamp should be red. A means must be provided so that any undue rise will not bend the lever. This may be accomplished by using contact springs instead of contact screws. It might be well to solder a small piece of silver at the contact points *A* and *B*. Lights *C* and *D* should be so placed in the engine room that the engineer's attention will be readily drawn to them.

Should no current be available, the signal could be arranged to work with bells, by placing 4 or 5 dry-cells across the lines, with a small bell at *C* and another at *D*. Of course the ring of these bells should have different sounds so that the engineer will know whether the water is high or low, thus indicating to him whether he should slow down or speed up the pump.

Cages for Hoisting Men—No operator of any mine should permit the hoisting or lowering of men through a vertical shaft deeper than 300 ft. unless an iron-bonneted safety cage be used, except during the process of sinking.

*C. F. Fuetter in "Coal Age," Nov. 13, 1915.

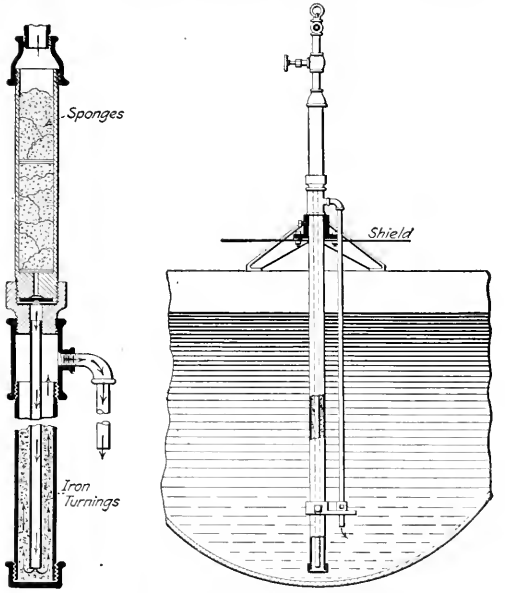
Details of Milling and Smelting

Bardill Drossing Apparatus

By J. O. Bardill*

The sketches accompanying this description illustrate a device for agitating the molten lead in the drossing kettles in the refinery of the St. Joseph Lead Co.'s smelting plant at Herculaneum, Mo. It has been in use there for the past four or five years.

When the archaic method of using "a green pole of ze fir (or willow) tree zat shall be perfectly dry," etc., was discarded, live steam from the boiler plant was substituted. It was conducted through a pipe line about



THE BARDILL DROSSING DEVICE

600 ft. long, weirdly devious in its course, besides possessing other features that make for general inefficiency and grief in operation.

This new device operates on the flash-boiler principle. The flow of water entering the generating chamber is fixed by an aperture about 0.020 in. in diameter in a diaphragm which separates it from a filtering compartment. The heat of course is derived from the molten lead. The filtering compartment is filled with a very cheap grade of sponges, with several thicknesses of copper-wire gauze placed above the diaphragm.

The iron lathe turnings in the generating chamber, for increasing the heating surface, were found to be unnecessary. The circular shield that is usually attached to the generator barrel at a point above the top of the kettle is also unnecessary. As the cost of these devices is low, an extra one is always kept in readiness for use in case the diaphragm's opening should become clogged.

Facilities for handling these agitators consist of a small chain block and trolley operating on the same I-beam track used in making kettle replacements. After submerging the generator, the filter compartment is connected to the water main by means of hose and coupling. This device is proof against accidents from blow-ups such as frequently occur through entering water when steam is obtained from some outside source. It is not so mussy, since there is no condensation to take care of as when the old system of steam is used.

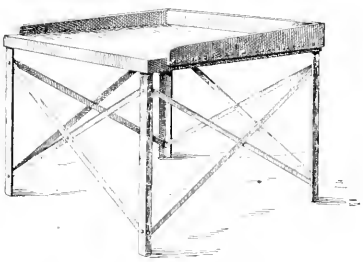
Compared with compressed air, as used in some plants, it is cheaper, particularly if a compressor must be installed and operated solely for this operation in refining.

*450 Lafayette Ave., Palmerton, Penn.

Steam-Jacketed Drying Table for Tailing Samples

The rapid drying of the considerable number of tailing samples taken daily at the mill of the Miami Copper Co. at Miami, Ariz., is effected by the simple steam-jacket table shown in the illustration.

The jacket has an internal steam space of about 3 in. and is 24 to 30 in. square. It is supplied with steam at 45 to 60-lb. pressure. The jacket is supported on



STEAM-JACKETED DRYING TABLE

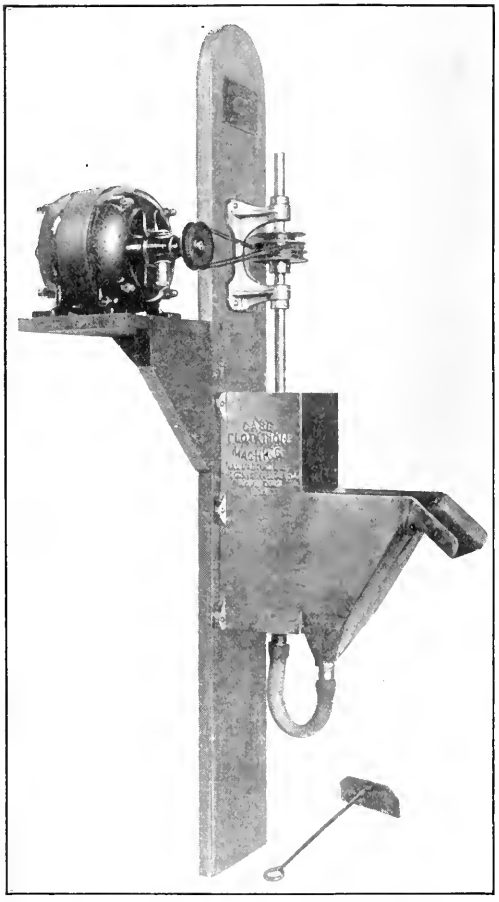
a stand of light 1-in. angle irons at a convenient height and slopes at a low angle to the back. Around two sides and across the back, there is riveted a steel edge that stands about 4 to 5 in. high at the back of the table, sloping to about 2½ in. at the front of the sides.

The tub of tailing sample is held on the edge of the table and all the sample is washed on the jacket by a stream from a hose with a small-diameter nozzle but with water at high pressure. The greater part of the water evaporates immediately upon striking the table, the temperature of the plate being considerably above the boiling point. In a few minutes all water is evaporated, and by the time the operator has loaded the sixth table the sample on the first is dry and ready to be removed. The rapid drying is extremely convenient for handling tailings, but probably the temperature would be too high to dry concentrated fine sulphides safely.

Laboratory Flotation Machine

To meet the demand for a simple and efficient machine for making flotation tests, the device illustrated here has been produced by the Denver Fire Clay Co., of Denver, Colo. The machine may be installed on any wall or post and is ready for immediate use.

The main, or cell, portion of the machine is made of cast aluminum, as is also the impeller. A feature introduced is the closed-circuit arrangement by means of a short length of high-pressure rubber hose, it being thereby possible to attain the same repetition in treatment as is otherwise accomplished in a multiple-cell machine. When this circuiting is not desired, a simple pinch-cock is applied to the hose.



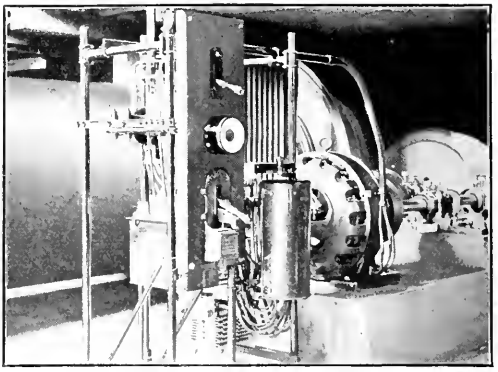
FLOTATION MACHINE FOR THE LABORATORY

The motor is rated at $\frac{1}{8}$ hp., has variable speed up to 1,800 r.p.m., is reversible and may be supplied for any electrical specification. The impeller shaft runs in bronze bearings and is provided with collars permitting the adjustment of the impeller to run at any desired depth in the agitation compartment.

Unit Tube-Mill Control

The tube mill illustrated is one of the regrinders used by the Homestake Mining Co., at Lead, S. D., and is one of the exceptional installations having individual motor and control.

At the top of the panel is the regular switch and just below it, an induction-type ammeter. At the bottom is an electromagnetic blowout switch. At the right is a controller of the street-car type, somewhat unusual in milling plants. The entire installation is of Westinghouse manufacture.



TUBE-MILL CONTROL AT HOMESTAKE MILL

New Zirconia-Carborundum Refractory Material

A new material said to be highly refractory has been patented by August Pfaff, of Freiberg, Germany (U. S. Pat. 1,159,264), consisting of a mixture of zirconia and silicon carbide, or carborundum.

This mixture has the advantage over zirconia in that it is not subject to cracking during alterations of temperature, nor does it become brittle and lose its mechanical coherence, while it withstands oxidation by air where the silicon carbide does not. If it is desired to obtain the maximum of refractoriness, the silicon carbide should be employed in the form of a powder coarser in grain than the zirconia.

The highly refractory qualities of the new material make it adapted for the manufacture of electric resistances for use in cases where it is imperative that the resistances shall be efficacious at high temperature. The material is molded into the form desired and then burned before using. A considerable shrinkage must be counted on in the burning operation.

Melting Aluminum Chips

H. W. Gillett, at the American Institute of Metals meeting, emphasized the great improvement in aluminum recovery in melting aluminum chips, if the chips were mechanically clean. As fluxes, zinc chloride, ammonium chloride or a mixture of salt and fluorspar is recommended. A reducing atmosphere helps, but the great difficulty is not oxidation but prevention of coalescence by the dirt mixed with the metal.

Mining & Metallurgical Machinery

The "Little Tugger" Hoist

A new type of hoist has been placed on the market by the Ingersoll-Rand Co., New York City. It is intended for light lifting and has a capacity up to half a ton. Owing to its light weight, which is under 300 lb. complete, it is particularly suitable for use as a portable hoist for mines, contract work and power houses.

The main base of the hoist is arranged so that it can be bolted to a timber, and by means of a cap that comes

"LITTLE TUGGER" HOIST PULLING CAR IN TUNNEL

with the hoist, it can be clamped to a circular member, as a mine column or arm, shaft bar or pipe. The adjustment can be made quickly. Mines are using it in winzes, stopes and raises, clamped to a drill column or stretcher bar, shaft bar or timber, for various purposes. The dimensions of the hoist are $21\frac{1}{4}$x$16\frac{1}{2}$ in., and the height is $20\frac{1}{8}$ in. The drum is 6 in. in diameter, with a space of 7 in. between flanges. This will accommodate a length of 700 ft. of $\frac{1}{4}$-in. rope or 450 ft. of $\frac{5}{16}$-in. rope. It operates with either compressed air or steam and has a capacity of 1,000 lb. at a rope speed of 85 ft. per min. and a pressure of 80 lb.

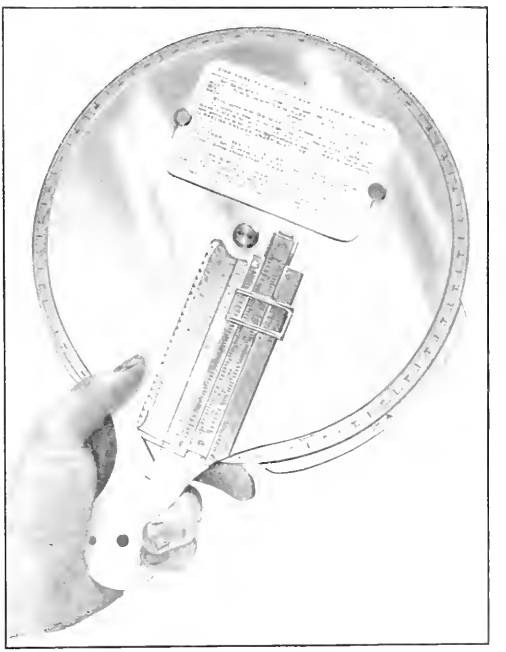
The motor, or engine, is of the reversible square piston type, giving four impulses per revolution of the engine. There are no dead centers and the "Little Tugger" will start in any position. Safety is provided for by a powerful worm-operated band brake lined with "Raybestos."

There are no moving parts exposed on the "Little Tugger" except the drum, all gears and shafts being covered.

Graduated-Spiral Slide-Rule

A slide-rule that may be directly read to four places and estimated to a fifth has been put on the market under the name of the Ross Precision Computer as an attempt to get the convenience of a slide-rule with the accuracy of a five-place logarithmic table. It is designed to be particularly useful for engineering computations and is the invention of Louis Ross, of San Francisco, who invented and now manufactures the "Meridiograph," described in the *Journal* of Aug. 1, 1914. The new device is manufactured by the Computer Manufacturing Co., 268 Market St., San Francisco.

The graduations are along a 29-ft. spiral on a disk about 8 in. in diameter, the upper members, 9 to 10, oc-



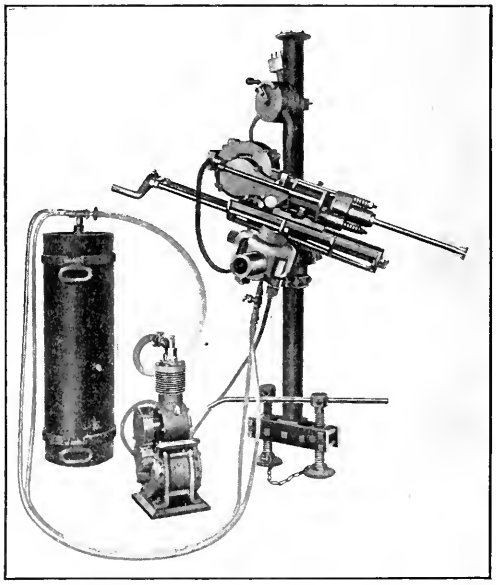
ROSS PRECISION COMPUTER—A SLIDE-RULE WITH GRADUATION ON A SPIRAL

cupying the outer portion of the scale. As a consequence the spacing is spread out by the increasing length of the spires, so that the 29-ft. scale is the equivalent of a 100-ft. rule. So great is this effect, that if the ruling were reversed, the scale would be equivalent only to a 16-in. rule. The outside ring of graduations is used in connection

with the quadrant scale to give five-place logarithms and antilogarithms for solving powers, roots and exponential problems. The operations of multiplication and division are as simply performed as with any logarithmic scale. The auxiliary 4-in. slide-rule on the face gives logarithmic numbers on the left-hand fixed scale and corresponding square and cube roots on the right-hand fixed scale. On the slide between are two logarithmic scales, both corresponding to the left-hand fixed scale but graduated in reverse directions. The computer is made of aluminum and german silver.

Denver Electric Rock Drill

An electric rock drill has been placed on the market by the Denver Rock Drill Manufacturing Co., Denver, Colo., in which it is claimed there are embodied some entirely new principles, which it is hoped will obviate the structural deficiencies and difficulties that have made mining men skeptical heretofore as to the benefits of the



DENVER ELECTRIC ROCK-DRILL OUTFIT

electric drill. This new device has been tried out by more than two years of practical service in mining.

The machine is a self-contained, direct-connected motor and cylinder unit and includes a small auxiliary electric-driven air compressor and an ordinary water tank, the function of the compressor being merely to supply air for cleaning the drill hole and to maintain pressure on the water in the tank used for drilling.

These drills require three-phase 60-cycle current, which may be used at 110, 220 or 440 volts, and transformers must be provided accordingly. The rotor shaft runs in ball bearings. Power is transmitted to the drilling mechanism by an internal reduction gear.

There are two cylinders in the main part of the drill. One contains a piston called the pulsator, mechanically reciprocated by the gears and a connecting-rod. Air is compressed in both ends of this cylinder and intermittently passed through end ports to the hammer cylinder (alongside) where it causes the hammer (not mechanically connected to any other part) to oscillate in step with the pulsator, striking about 1,200 blows per min.

On the outer side of the pulsator cylinder is a bypass device, by which the air in the pulsator cylinder is shunted from the hammer cylinder and caused to pass back and forth to opposite sides of the same cylinder. By this means the hammer may be stopped instantly or its blow may be adjusted to any degree without shutting off the electric current or interrupting any other function of the machine.

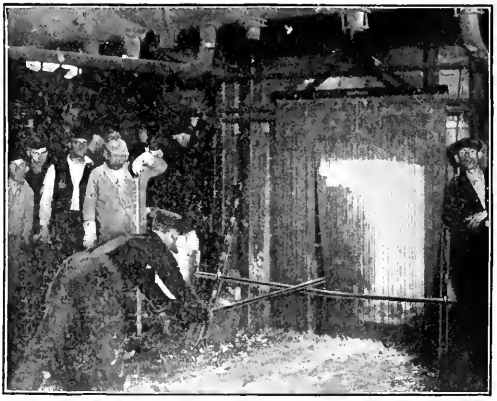
Rotation of the drill steel is effected positively by a ratchet and slip friction gearing. The steel will continue turning if the hammer be stopped by the bypass, and the machine as a whole may then be used as a boring tool. The loss of a hole by "fitchering" is rendered practically impossible. The drill steel is round and hollow, and a portion of the shank about 1 in. long is forged square.

The feed is by means of the usual screw and shell. The switch is so made as to render the drill runner safe against electric shocks.

Among the advantages claimed by the manufacturers for this machine are: Small power consumption, drilling speed, freedom from fitchering, lack of freezing trouble and low original cost.

Wiegand Chain Screen Door

A decided metallurgical novelty seems to be contained in the Wiegand chain screen door manufactured by the E. J. Codd Co., of 700-708 South Caroline St., Balti-



WIEGAND CHAIN SCREEN DOOR

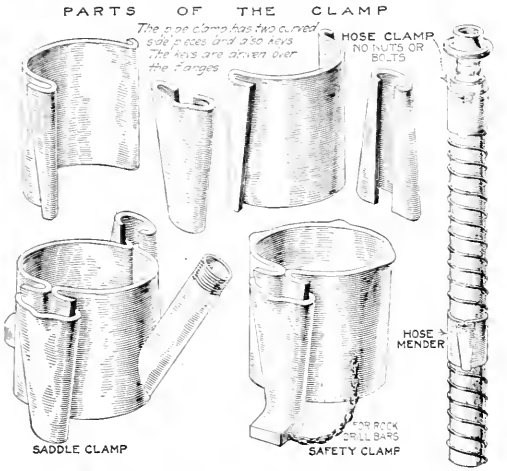
more, Md. This door consists of a number of freely suspended individual strands of steel chains, which form a curtain not unlike the familiar Japanese screen.

This screen to a great degree protects the workmen from the rush of hot air and furnace gases and from the glare of the interior of the furnace when the door is open. It also prevents undue chilling of the furnace by an inrush of cold air. Yet it can be seen through and can readily be pushed aside to introduce tools. So far this device has been chiefly used in connection with glass

furnaces and glass pots, and boiler furnaces, but there seems to be no reason why there is not a wide adaptability to refining and reverberatory smelting furnaces.

Underground Pipe Fittings

Such fittings as are shown in the accompanying illustration have proven economical and useful in the Rand mines. They facilitate repairs with speed and safety

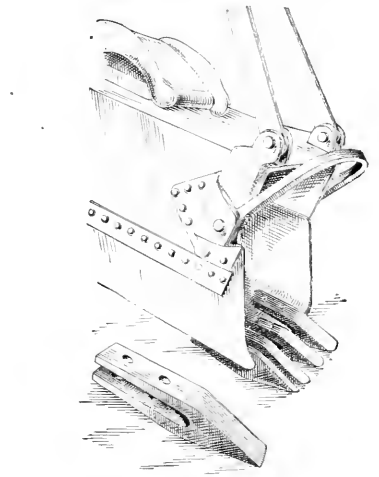


SIMPLE CLAMPS FOR UNDERGROUND USE

on water and air pipes and air hose. They are known in South Africa as the Ussher fittings and are patented there.

Easy-Loading Dipper Tooth

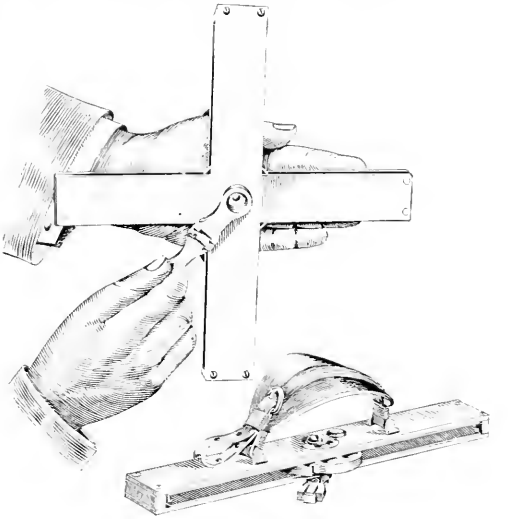
An easy-loading style of one-piece tooth for steam-shovel and dredge buckets has been designed and is being manufactured by George P. Chambers, 110 North Madison Ave., La Grange, Ill. The device is shown in the accompanying sketch. The tooth is made of carbon steel for resharpening or manganese steel for especially severe service. The teeth are reversible, so that when worn on one side they may be turned over and re-used. It is claimed that a bucket equipped with these teeth loads more material than with any standard tooth, and that particular benefit has been shown in picking up large stones on level ground. These teeth are used at several quarries in Illinois.



CHAMBERS REVERSIBLE DIPPER TOOTH

New Reel for Flat Wire Tape

A new four-arm folding reel has been put on the market by the Keuffel & Esser Co., of New York. When using tapes over 100 ft. long, it is customary to use the tape without a reel, the latter being carried separately. This is generally inconvenient, especially if the reel is bulky.



FOLDING REEL FOR 100-FT. TAPE

The present device has therefore been designd to obviate this advantage.

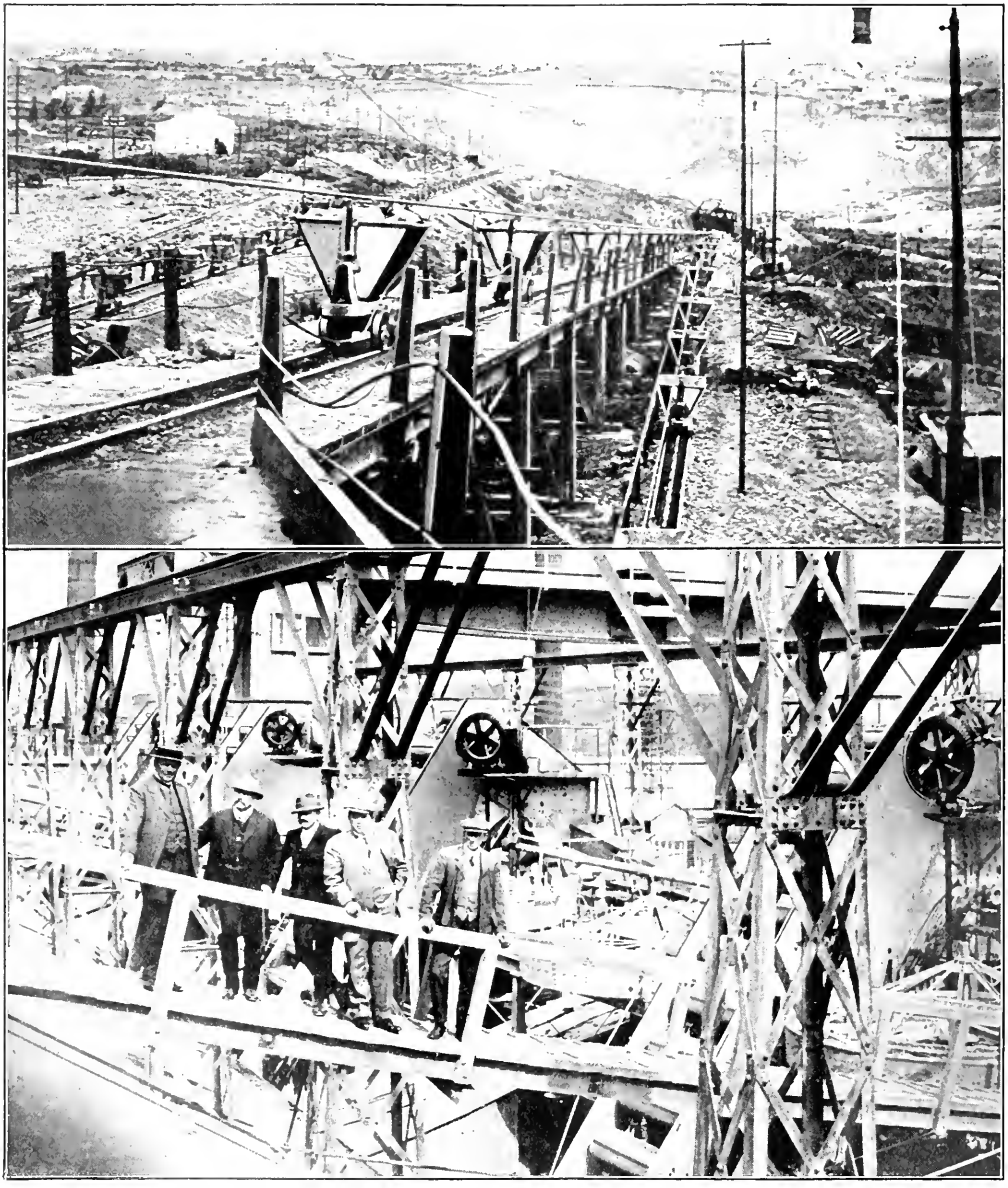
When the tape is off, the cross-piece can be folded into the frame and the reel, now a single flat piece, can be conveniently carried in the pocket, so that it is immediately available when the tape is ready to be wound up again. The frame is made of nickel-plated steel, in three sizes, holding $\frac{1}{4}$-in. steel tape from 100 to 500 ft. long.

Globe Patent-Lock Roofing

A new kind of lock roofing is being offered by the Globe Iron Roofing and Corrugating Co., of Cincinnati. The novelty is in the lap lock, which is so designed that the joint can be promptly and easily made, and will stay waterproof. The roofing may be had in plain or corrugated sheets or in the shingle-cluster form.

The Denver Engineering Works Co., of Denver, Colo., has published a bulletin (No. 1078) on ball mills, in which some interesting data are given. The special feature of these mills is the tire-and-roller type of bearing at the discharge end, permitting the use of a large discharge opening. This removes the necessity for screens, diaphragms, etc., and makes a simpler machine. The discharge opening is fitted with the Neal reverse spiral to permit escape of the balls.

Photographs from the Field



TWO VIEWS OF DIAMOND-MINING OPERATIONS ON THE SOUTH AFRICAN FIELDS

The upper illustration gives a general view of haulage operations. Cars of diamond-bearing ground are taken from the opencuts by a rope-haulage system, a continuous stream being carried to the dumping point and returned to the cut on a lower level. The lower illustration is a general view of the washing plant.

Pulmonary Disease Among Miners

That the inhalation of sharp particles of dust injures the mucous membrane of the lungs and in this way lessens the resistance of the lungs to pathogenic germs, especially the bacilli of pulmonary tuberculosis, has been proved by investigations of morbidity among workmen in dusty trades and by study of the prevalence of lung diseases in South Africa and other foreign countries. The matter is one of deep public concern, and attention has been called to it from time to time.

Recently, with a view to affording some measure of relief through suggested educational work and through state legislation, the Bureau of Mines has undertaken, in coöperation with the Bureau of the Public Health Service, preliminary investigations of the production of dust in metal mines in various parts of the United States and the relation of the prevalence of dust to silicosis, or miner's consumption, and pulmonary tuberculosis among miners. Passed Assistant Surgeon A. J. Lanza, detailed to the Bureau of Mines, and Edwin Higgins, a mining engineer of the bureau, coöperated in making a survey of conditions in various metal-mining districts of the United States and made a report[1] dealing with the prevalence of tuberculosis among the miners of the Joplin district, Missouri. The following summary of conclusions and recommendations was made:

Summary of Conclusions Arrived At

1. The death rate from pulmonary diseases is unusually high among the miners of the Joplin district.

2. Poor housing, exposure, alcoholism, the use of common drinking receptacles and overwork, all tend to spread infection and lessen the power of the miner to resist disease, but the prime factor in causing pulmonary trouble is the rock dust in the mines.

3. Rock dust in the sheet-ground mines, although not made in great quantity as compared to mines with more restricted working places, is harmful to the miner for two reasons—because he is exposed to it practically during his entire shift, and because the dust is made up chiefly of particles of insoluble flinty chert with splintered and knifelike edges.

4. This rock dust is produced by the blowing of dry holes, squibbing, boulder popping, drilling without water, shoveling, tramming, roof and pillar trimming, and the dumping of the bucket at the surface.

5. By observing certain precautions rock dust in the mines can be almost completely abated.

6. There are certain abuses connected with the piece system of work that demand attention and correction as far as practicable.

Recommendations for Allaying Rock Dust

1. The following means should be employed for the abatement of rock dust in the mines:

a. Provide a water-supply for every working face by the laying of a separate water line.

b. Where drills are operated without water, attach to the hose leading to the face a 5- or 6-ft. length of pipe with a nozzle from $\frac{1}{8}$ to $\frac{1}{4}$ in. in diameter. Make and enforce such regulations as will insure the use of this water spray for the purpose of wetting drill holes, the face, and the broken rock about the face. For the purpose of washing drill cuttings from drill holes, this hose may be attached to the long pipes now in use for blowing-out drill holes.

c. Where there is in use some type of drilling machine that provides for water passing through the core of the drill steel into the drill holes, make and enforce regulations that will insure the spraying of the face and broken rock for short periods at such times as the drill may not be in operation. For this purpose the water hose must be uncoupled from the drilling machine unless separate water connection is provided.

d. Make and strictly enforce rules against squibbing and boulder popping while the shift is underground and against the blowing of dry holes at all times.

e. Improve ventilation by the opening of new shafts whenever practicable.

2. Do away with common drinking cups and kegs, and water pipes that allow the miner to bring his lips in contact with the orifice. Substitute the well-known sanitary drinking fountain when practicable, or have miners bring their own drinking water in individual containers.

3. Do not employ as shovelers men under 20 years of age.

4. Through coöperation among the operators, stipulate a maximum daily tonnage for shovelers, so that they cannot injure their health through overwork.

5. Provide a warm, dry and clean place in which the miners may change their clothes.

6. Through intensive educational campaigns in the public schools and among the miners themselves, disseminate information as to the harmful effects of insanitary practices and conditions, such as crowded living quarters, overwork, exposure, dissipation, the breathing of air polluted by powder fumes and rock dust, and the use of common drinking devices.

[1]Technical Paper 105, Bureau of Mines.

A One-Leg Ore Trestle

Brainerd Correspondence

A new ore trestle just completed at the Wilcox mine, Woodrow, Minn., presents some features novel, at least, to Cuyuna Range operators. It is of the one-leg type, the legs being 6-in. wrought-iron pipe 36 ft. long set in concrete foundations and themselves filled with cement. A flange coupling at top and bottom permits connection with foundation and crosscaps. The legs are then guyed with $\frac{5}{8}$-in. cable.

This constitutes the permanent trestle, beyond which are two bents of wooden-post trestle, where the ore is dumped. End-dump cars are used until the ore pile is of sufficient length, when side-dump cars will be used to make additions alongside.

Such arrangement leaves a stockpile free from timbers to interfere with steam-shovel loading.

More Dredges in Colombia

The Anglo-Colombian Development Co., which is operating in the gold-platinum region in the western part of Colombia, contemplates the installation of more dredges on the Condoto River. At the recent annual meeting in London of the Consolidated Gold Fields of South Africa, Lord Harris stated that the dredge which has been in operation since July had obtained results

that fully justified considering ways and means of producing gold and platinum on a larger scale by the provision of more dredges. An engineer has been sent to Colombia to investigate the conditions affecting the development of power for additional dredges and an enlarged scale of operation.

Besides this prospective increase, mention has previously been made of the program of construction contemplated by the Oroville Dredging Co.'s subsidiaries in the Nechí Valley in central Colombia.

The Deepest Gold Mine, Morro Velho

The deepest gold mine in the world—the deepest mine of any kind, it is believed—is the Morro Velho in Brazil, owned by the St. John del Rey Mining Co. Some particulars about it are given in the annual report lately published in London.

For the past three years the lowest developed horizon has been the 18th, at a 4,900-ft. depth from adit level, equal to 5,226 ft. from surface. For the purpose of attacking ore at greater depth shaft G has been sunk from the end of a tunnel at the 16th horizon, and from this shaft horizons 19 and 20, respectively 5,202 and 5,502 ft. below adit level, have been commenced. The 19th horizon is expected to be developed and ready for raising ore by June next, and the 20th horizon by April, 1917. The opening up of these two new levels is expected to add something like 600,000 tons to the ore supply, and it is believed that values will be maintained.

If the mine could be worked down to the 20th horizon only, it might be assumed that its life would not be longer than about six years. However, there is no intention to stop work at the depth attained by the 20th horizon. The superintendent's last annual report deals very exhaustively with this subject. He says, in effect, that except for the rapidly increasing temperature of the mine, supposing the lode continued the same size and value to horizon 26 (vertical depth 7,626 ft.), it could be worked profitably to that point and even to a greater depth, but from the temperature chart the rock at horizon 26 would be no less than 126.5° F. at the moment of opening. It is not believed that much more can be done in present circumstances in the matter of increasing the volume of ventilating air, but the opinion is advanced that by artificially cooling the air passed down the mine the difficulty can be overcome and the mine worked to considerably greater depths than yet reached. An air-cooling and drying plant has been designed which, it is stated, "represents a thoroughly practicable scheme that will effectually remove the one serious obstacle against the company being able to work the mine to a great depth."

Molybdenum and Tungsten in Chile

A report from United States Consul J. W. Voetter at Antofagasta, Chile, mentions recent reports that at the mining community of Campanany, in the Province of Tacna, Chile, there exist considerable deposits of molybdenum and wolfram, in addition to copper sulphides. While the mines have not been developed, samples of the ores have been sent to Europe for the purpose of finding a market for the minerals. The address of the president of the mining community is Sr. Jorge Romussi, Iquique, Chile.

Newspaper reports also state that a good vein of wolfram has been discovered in the property of the Cia. Estañifera del Llallagua, at Llallagua, Bolivia. The principal office of this company is at Santiago, Chile.

Lake Superior Iron Outlook

ISHPEMING CORRESPONDENCE

Navigation will be about at an end within a few days, and the mining companies and boat companies are already making their plans for 1916. Never in the history of the iron-ore business has there been such optimism as one hears in the Lake Superior district today. The question is not how much ore can be mined, but how much the lake fleet will be able to transport to lower lake ports. It has been estimated that 55,000,000 tons will go down next year, but other opinion doubts that the boats will be able to handle any such tonnage. However, it is probable that the record of 50,000,000 tons, made in 1913, will be surpassed. There has been an advance of 10c. a ton for carrying ore next year, and a large number of the boats have already been chartered. The Steel Corporation entered the field first and chartered a great deal of tonnage, in addition to its own fleet operated by the Pittsburgh Steamship Co.

Just what prices will be received for iron ore in 1916 it is impossible to forecast now. A dollar advance is predicted, while 50c. advance seems certain.[1] The operators are making preparations to get out a maximum tonnage, and nearly all of the underground mines in the Lake Superior district will be worked this winter. New mines are being developed and opened. The Arthur Mining Co., which took over the Hill properties on the Mesabi, is ordering equipment and doing a lot of stripping. The same is true of other Mesabi concerns. Oglebay, Norton & Co. are to put the Meteor shaft, on the Gogebic range, down so that the ore can be tapped. The Hanousack, on the same range, is to be stripped; Butler Bros. have the contract. The Cleveland Cliffs Iron Co. is to sink a shaft and mine ore on what is known as the Junction Forty, on the Marquette Range. Corrigan, McKinney & Co. are to sink on the Adgers lands on the Menominee range.

The concerns that furnish machinery for the mines of the district are flooded with orders. Rock drills, compressors, hoists, steel, etc., are badly needed. The companies have kept their purchases at a minimum during the dull times, but now that they know that they are going to be able to sell all they mine, and at better prices, they want the necessary tools.

It is feared that there may be shortage of labor next season. Many foreigners have gone from the Minnesota ranges to Europe during the past year, and many miners have left the district for other camps when things were dull on the iron ranges, being attracted by the high wages being paid to copper miners in Butte, Bisbee and other Western copper camps. There will probably be plenty of common labor for surface work and work in the pits, but a scarcity of first-rate underground men would not be surprising.

[1] According to telegraphic reports of Dec. 8 the advance is about 75c.—Editor.

Lake Superior optimistic operators expect 1916 to be a big year in the iron ore business, but 1917 and 1918 to be still bigger.

Chronology of Mining for November, 1915

Nov. 1—Canadian Copper Co. adopted eight-hour day for all men at smeltery and shop, and granted increase to men in mines working on an hourly rate.—Gaylord mill, Cripple Creek, burned to the ground.

Nov. 2—Strike at Thetford mines, Quebec, settled.

Nov. 5—Concentrator of Arizona Copper Co., Clifton, Ariz., destroyed by fire.

Nov. 6—Strike at Nichols copper refinery.—Ray-Jefferson stockholders voted to increase capital stock from 1,500,000 shares to 2,000,000, par value, 25c.

Nov. 9—Strike at Silver King Coalition mine settled.

Nov. 10—Alice mine, Butte, reverted to Anaconda company, no offers having been made when offered at public sale.

Nov. 11—Mill of National Copper Co., Idaho, started operation.

Nov. 14—Law enacted in Peru levying export duty on gold, silver, lead, copper and other metals, and on borax and petroleum.

Nov. 16—Commencement of suit between Alameda Mining Co. and Success Mining Co.—Strike at Nichols refinery settled.—Explosion in mine of Northwestern Improvement Co., at Ravensdale, Wash.; 34 men entombed, of whom three were rescued.

Nov. 17—Announcement of Kennecott-Braden consolidation.

Nov. 22—Federal investigation of Clifton strike begun.—Villa reported driven out of Cananea.

Manganese Developments in Virginia

ROANOKE CORRESPONDENCE

The actual results, so far, accruing from the renewed interest in the manganese deposits of Virginia, due to the war market for the ore, have not been so satisfactory as was hoped for a year ago. There have been a great deal of negotiating and several attempts at financing, and engineers, ore buyers and investors have worn quite bare the trails in the best known manganese-bearing areas.

The Crimora mines properties at Elkton, one in Rye valley and several others have, however, received serious attention, and with good results as far as development has progressed. The Piedmont Manganese Co.'s mine, near Lynchburg, has been reopened and promises soon to resume shipments. At Crimora the consummation of the very extensive equipment and financial program has delayed actual output. At Elkton litigation as to title has kept back recent negotiations. In Rye valley, financial mishaps in Philadelphia postponed the completion of what promised to be a successful operation to mine manganese and manganiferous iron ore. Numerous smaller operations have realized small shipments. On the whole, outside capital has not yet come to take the Virginia deposits very seriously, and local capital is not available ordinarily for even the prospecting of the many promising deposits in the Piedmont, James-Staunton River, and the southwest Virginia districts.

United States Motor Trucks for Bolivian Tin Mines

SPECIAL CORRESPONDENCE

Alexander Grosberg, of the Patiño tin mines, recently left St. Louis for Uncia, Bolivia, where the mills and mines of the company are situated. While in the United States Mr. Grosberg arranged for the construction and purchase of a large number of motor trucks to be used in transporting tin and concentrates from the mills to the railroad. The transportation problems there are unusual, and the introduction of motor trucks of American make is of great importance to manufacturers in the United States.

The contract for transporting the concentrates of the great tin mines of the Llallagua and Patiño companies is now held by a single transporting company. The distance from the mills to the railroad is about 60 mi., the average grade 4½% and the maximum grade 15%. During eight or nine months the roads are good, but during three or four months of the rainy season the constant and heavy traffic makes the roads almost impassable. During the dry portion of the year six mules are used on each cart carrying 8,000 lb. of ore, with an addition of six more mules at the worst grades. During the wet season six mules are used for each cart carrying 4,000 lb. of ore, with an addition of 12 mules at the points of worst grade. The contract specifies that all concentrates produced during a given week must be delivered at the railroad by the end of the following week, heavy penalties being imposed when this part of the contract is not fulfilled.

It is now proposed to substitute motor trucks for this work. Trucks for this use must have special features, especially in connection with the cooling system and traction. For the latter a four-wheel tractor is proposed. The first order of trucks will be for about 30. If these are successful, it means that motors will supplant all other methods of transportation on the Oruro plateau, and that thousands of American-made cars will be required for this work.

It is evident that one of the best methods of securing South American trade is the education of American engineers for this field. Mr. Grosberg was graduated from the Missouri School of Mines in 1911.

Porphyry Copper Dividends

At the meetings of the porphyry copper companies held on Dec. 8 the following dividends, payable Dec. 31, were declared: Chino, $1 quarterly; Nevada Consolidated, 37½c. quarterly and 12½c. extra; Ray, 50c. quarterly; Utah, $1.50 quarterly. Butte & Superior declared a regular quarterly dividend of 75c. and $7.50 extra.

Phosphorite Deposits in Russia are being investigated under the direction of the Ministry of Agriculture. So far the only deposits found to be of any commercial value are those on the Upper Kama River. These, containing 27 to 28% of phosphoric acid, are worthy of consideration for both quality and quantity, as well as the fact that they are situated near the deposits of iron pyrites in the Ural Mountains.

Editorials

Carrie Everson

Ever since the flotation process established itself the name of Carrie Everson, the first patentee of a flotation process that bore the earmarks of experimentation, has been on the lips of all metallurgists. Many efforts to learn something about her have been made, all of them unsuccessful until recently, when some members of the Colorado Scientific Society traced her. Most of the searchers had previously come to the conclusion that probably she had died long before. Strange to say, she was living at that very time and had failed to make herself known during the excitement of patent litigation and the common talk about her. Unfortunately she died only about a year ago, but before anybody had been able to interrogate her about her invention.

According to the Denver *Times*, Carrie Everson was the wife of a Doctor Everson, a physician who had been practicing in Chicago. She was born in Sharon, Mass., in 1842, her maiden name being Carrie Jane Billings. Early in the '80s the Eversons moved to Denver on account of the doctor's health. He died a short time afterward. Everett A. Fay, a bookkeeper in the Denver National Bank, who knew the Eversons, is reported as saying that the discoverer of the flotation principle was Doctor Everson. After his death his widow pursued the idea, took out the patents, and for his aid in promoting the process let Criley, a Denver blacksmith, become associated with her. She continued her experimental work for several years. She lived in Denver until 1909, when she joined her son, John L. Everson, in San Anselmo, near San Francisco, where she died Nov. 3, 1914.

Members of the Colorado Scientific Society are now trying to get at the facts of the Eversons' discovery and will propose some fitting testimonial to them. The legend of the Denver spinster-schoolteacher washing the ore-sacks of her assayer-brother seems to have been destroyed. In this interesting history there stand out two things, namely, the quiet life of Mrs. Everson in the time when she had become an international figure, and the unanimity with which she is hailed by Americans as the real discover of the flotation process, although the owners of certain patents deny it.

⁂

The Situation in Copper

The little recession that has occurred in the price for copper during the last fortnight is devoid of any broad commercial significance. The users of copper have bought very liberally, and most of the producers have sold—at fine prices—their expected output for a length of time ahead that is far beyond their ordinary hopes. The users naturally cannot keep on buying indefinitely; on the other hand, producers when sold ahead so well as they are now are indifferent whether they do new business every day or not. Indeed, they do not expect to.

However, there are many small producers of crude copper, not in a position to enter into contracts for the delivery of refined, who need to sell their output right along in order to keep going. This copper is often to be had by traders and refiners on favorable terms, and against such purchases refined copper may be sold at only a slight advance. Persons trading thus in copper will sell it for what they can get, so long as there be any profit in the transaction. Consequently prices are apt to sag off in a narrow trading market, but when a large demand for copper develops again, the market is likely to rise to the terms of the big producers, if the statistical position be sound. If the statistical position be hollow, a sagging in prices after the culmination of a big advance is apt to foreshadow a pronounced downward trend, the big producers usually coming into the market again at a much lower level, after the old orders on their books have been exhausted. At the present time it is believed that the statistical position of copper and all of the fundamental conditions are of very strong character.

⁂

How the Metals Are Sold

The quantity of the principal metals—iron, copper, lead and zinc—that is sold to consumers out of warehouse, or "on the spot," is relatively insignificant. The bulk is sold on contracts for delivery during the ensuing two or three months, the buyer covering what he expects to use during that period and taking delivery more or less at the mutual convenience of himself and the seller. Thus he may request the seller to advance or delay the stipulated delivery, and in general the latter is glad to oblige his customer and does so if it be possible. In lead only does an essentially different method prevail. The principal producer of this metal has long maintained the custom of selling only for shipment within 30 days, although its competitors sell their lead just as other producers sell their copper and spelter. However, a very large part of all the lead used by consumers in the United States is sold to them on long-running contracts, settlements being made on the monthly quotational averages.

In making the usual contracts for copper and spelter there is ordinarily no discrimination as to prompt and futures—that is, within the ordinary deliveries in the trade—or if there be any, they are but trifling. At certain times when stocks have been reduced to a small figure—for example, in the case of copper in 1906-7—the belated buyer who had to have immediate delivery was obliged to pay a premium, but such of course was no more representative of the broad commodity market than the expenses of a belated traveler who has to hire a tugboat to put him aboard the steamship are a measure of the current fare to Europe. Lumped with the whole volume such premium business figured disappearingly small.

There is of course at all times some freakish business that partakes of the nature of a betting transaction. Thus, copper being at 15c., somebody may offer to buy at 13c.

a large quantity to be delivered during the next 12 months and may find somebody to take him up. In such a case the buyer may be covering his requirements for manufactured wares previously sold, while the seller may figure that the trend of copper is downward and that his sale would look good if the metal should happen to sink to 12c. or 11c. But transactions of this sort are unusual.

The uncertainties and extraordinary conditions produced by the war, however, have led to a great many transactions that are unusual. The most remarkable exhibitions of these have been in spelter. In this metal we witnessed first a practical disappearance of stocks, a loss that always deprives a market of its balance wheel. This was followed by the payment of large premiums for prompt delivery, while the ordinary two months' and three months' contracts could hardly be made at all. Then there was a wild rush for the metal and contracts covering six months or more were made, there being practically no limit to what buyers would do. At some times there would be a backwardation in price for future months, and at some times there would not be any to speak of. It was all a grand mix-up.

Recently there was a new feature, in that for a while there was scarcely any business for the quarter immediately ensuing, while rather a large business was transacted for delivery in the quarter next following. This produced a condition of spelter being sold at 13@14c. for one quarter and 10@11c. for the next. A pronouncement of what is the spelter market under such conditions was necessarily arbitrary. For the first quarter spelter was difficultly salable, but producers maintained a relatively high price. For the second quarter they were glad to take 3c. less, believing that when the time came the contract prices would look very high. On the other hand, there were buyers, chiefly foreign, who were willing to engage large tonnages at the figures named.

The copper business has at times exhibited irregularities, but none so erratic as in the case of spelter, for the copper market never lost its balance wheel of an available stock of the metal. At one time—in the height of the great selling movement of May-June—contracts for copper a very long way ahead were entered into, but these were at the prevailing price. Not long ago there was some maneuvering by producers to get some good contracts for distant deliveries on their books at the expense of apparently less advantageous sales of early supplies. However, abnormal transactions of all sorts are to be expected while the entire commercial machinery of the world is disarranged in the way it is and while speculation of all kinds is so rampant.

The Situation in Mexico

The warfare in Mexico appears to be all but over. Carranza and his followers have won. The victors are now trying to restore order in the land. This will be a matter of some time. There will no doubt be maraudings and guerrilla operations for many months, but gradually those should cease.

The big mining and metallurgical companies are taking active steps to resume operations. They report surprisingly little destruction of their properties. However, they are hampered, and will be for a while, by the destruction of railways and railway equipment. Probably they will be obliged to help the Government supply the latter, the Government having but little money of its own to spare. In other words, the larger companies, which must move freight, will no doubt buy locomotives and cars for the railways and accept reimbursement in the form of deductions from their freight bills.

Some private traders of more adventurous instinct than others are already going into Mexico. These early birds may reap large profits, but of course they will be exposed to great risks. We have been asked by numerous machinery manufacturers whether the time is yet ripe for them to send their travelers into Mexico to go after business. Great business is going to come to them from Mexico, but we think it is still premature to inaugurate regular measures for getting it. However, the time for them will come ere long.

Mine Taxation Problems

The enormous profits realized by some of the companies supplying military material were bound to attract the attention of the tax gatherers. Thus some persons in New Jersey are getting excited over the New Jersey Zinc Co., whose Franklin mine is assessed for taxation at a valuation of about $2,500,000, it is alleged, while the company pays annually many millions in excess of that sum as dividends. The system of taxation that prevails in New Jersey requires mines to be assessed at an absolute value, just like real estate, the New Jersey tax laws being similar to those of Michigan and a few other states.

An absolute valuation of the Franklin mine would be something of a job. Experts would be rather reluctant to undertake it. However, the inexpert are wont to rush in where the experts fear to tread. The ore of the Franklin mine is taken over into Pennsylvania for smelting, wherefore it is a puzzle to discriminate between mining profits and smelting profits, besides which there are some knotty problems in between. Moreover, the New Jersey Zinc Co. has extensive mining and smelting interests in many other states.

Prospects for the American Consulting Engineer

Note has previously been made in the *Journal* of how seriously the mining companies of Great Britain are being affected by the new taxes, which in certain cases are figured as taking two-thirds of the profits, when they are added to the older and local taxes. Obviously there exist but few mining companies that can stand such a burden, and it is only natural that some of them are considering the transferal of their headquarters to New York. Especially would such a transfer seem to be logical when the properties are situated in this country or in its neighbors to the north and south.

We may look also for a migration hither of Anglo-American and British engineers. If the mining companies come they will naturally have to come too. Another incentive will be the probability that American capitalists will soon begin to participate in foreign enterprises, especially in Russian, in which these men are experienced. There may be, indeed, a revival of the practice of consulting engineering, which for many years has been a dead profession in New York.

BY THE WAY

A geological map of Tennessee has just been issued by A. H. Purdue, state geologist of Tennessee. A copy may be had by sending 10c. in stamps to him at the State Capitol Annex, Nashville, Tenn.

⁂

Capt. Laurance Angel, U. S. A., according to the "Boston News Bureau," estimates taxable property in New York City at $10,000,000,000, of which amount at least $5,000,000,000 is subject to destruction by an enemy. He believes it is cheaper to insure this property by increasing the army and navy than to pay the ransom which a conqueror of the city would demand.

⁂

War and war conditions have had a disastrous effect on the diamond business. An evidence of this is found in the statement that during the first four months of 1915 only 64,977 carats of diamonds were exported from British South Africa, against 1,524,640 carats in the corresponding months of 1914 and 1,862,126 carats in 1913. Diamond mining in German Southeast Africa has ceased entirely for the present.

⁂

The first tube mill was introduced into the United States by J. R. Alsing in the late '70s. These machines were known at that time as "pulverizing cylinders," and those who imagine that the short tube mill is a modern development will be surprised to learn that the size of the early mills was 6x6 ft., according to our informant. The first pulverizing cylinder was made by the firm of Ball & Jewett and was installed in the Union Porcelain Works at Greenpoint, Brooklyn, where it was used for grinding pottery material such as feldspar and similar minerals. About 1880 some mills were built that were 6x8 ft. These were called "Jumbos" at this period. The pulverizing cylinders were soon introduced into the talc industry at Gouverneur, N. Y., but have not received such wide adoption in this industry as they have in metal mining, where the practice in some branches seems to be veering back to mills of practically the original proportions.

⁂

Miss Anna List, the famous syndicated lady psychologist, has at last completed her great life work—a delicately wrought analysis of Success, says *Judge*. For years the unsuccessful portion of humanity, comprising in all somewhat over 99% of the population of the globe, has waited impatiently for some authoritative information in regard to the chimerical composition of this irresistible force in business, political and religious circles.

SUCCESS

Honest work	1.027
Other work	25.878
Honest advertising	00.023
Ordinary advertising	17.101
Finesse	6.008
Surreptitious credit-taking	19.020
Ruthlessness	9.009
Luck	13.013
Hypocrisy	8.921

With this heretofore carefully concealed information now in the hands of Tom, Dick and Harry, a great injustice will soon be dissipated. Instead of a favored few being blessed with a lion's share of Success, Success will be equally divided among all, and nobody will have any to speak of.

Eureka, Nev., has been dying by inches ever since the furnaces and refineries closed down 25 years ago, writes Charles E. Van Loan in the *Saturday Evening Post* of Sept. 4, 1915. She may linger on for years to come, but so long as breath remains in the last inhabitant it will not be safe for the stranger to say Eureka is dead. Ore? They have trainloads of it—not so rich as it used to be, of course, for the old companies got the cream of it; but they only skimmed the top. Nobody knows what lies under the water in the Locan shaft on Ruby Hill. So Eureka waits. A traveling man passed through the town during Mr. Van Loan's visit. It was his first trip, the weather was very warm, the altitude bothered him, there was no ice to be had, his sales did not amount to much, and he had time to listen to the old men on the street corners. He paid them an entirely mistaken compliment before he cranked his roadster and sprinkled them with the dust of his departure. "The place is dead, but they don't know it," said he. "They can kid themselves along if they like, but they can't kid me. At that I've got to hand it to 'em—they're the greatest boosters in the world!" Thus he proved he knew neither the country nor the people.

⁂

An advertising circular of a recent book on Peru has been received, from which we purpose to quote at length. "All of the data in it is compiled from official sources of the Peruvian Government, and large quantities of gold dust have been panned out and obtained by the author's associates in Peru, and thousands of dollars of pure flake gold dust have been sold by the author at the United States Mint in Philadelphia, all of which has been panned out by hand from the golden streams of Peru." An illustration showing a large number of moving-picture actors, all looking proud, pleased and happy, is said to show "the art of panning gold from the sand and gravel of streams. Special instructions are given in the Guide enabling a greenhorn to successfully pan gold from the river-bed. The instructions are plain and simple, and easily learned by anyone. Working examples are given, so that the student may practice gold panning in his backyard by means of a wash-tub, from sand and gravel and a few grains of lead. This will make him expert enough so that when he reaches the field he will be able to pan and find color on any of the streams with ease." Except, of course, the gold be of the Santo Domingo variety, which can only be panned out by one who is used to that particular locality. We also learn that "the chinchilla is a native of the mountains of Peru and is worth $75 a dozen in New York City. Hundreds of these may be shot by any man handy with a shotgun," and shipped by wireless, we imagine. "The land cleared of its trees, with the exception of rubber trees, and other rubber trees planted in the same ground will produce on a 40-acre farm an income of $10,000 a year with little labor, and will support a family while waiting for the new trees to produce, which takes from five to eight years' time. Land may be purchased at $1 an acre." Now again we call your attention to the fact that all of this is not put forth with the idea of getting tourists, prospectors or rubber planters in South America, but merely for the sake of selling a book, at the small sum of $1.50 per volume. Do your Christmas shopping early while the first edition lasts.

PERSONALS

S. F. Shaw is visiting mines at Grass Valley, California.

Charles M. Schwab has been chosen a trustee of Cornell University at Ithica.

Charles A. Chase has changed his address to Suite 812-824, Cooper Building, Denver, Colorado.

E. Norris Hobart has been examining tungsten prospects in the Oscura Mountains in New Mexico.

Stanley G. Bullock, of the Poderosa Mining Co., Chile, has sailed for England to offer his services in the war.

H. Numato, engineer in charge of construction in the Imperial Steel Works, Japan, is a visitor in Baltimore.

Harlan H. Bradt is doing special work on iron ores for the Wisconsin Geological Survey. His present address is Lake Mills, Wisconsin.

Henry P. Day, superintendent of blast furnaces for the Tata Iron and Steel Co., Satchki, India, is making a vacation visit in this country.

George Kingdon, who had been spending a few days in Globe, Ariz., left Nov. 28 for the border to prepare for resumption of work at Cananea.

B. Magnus is on a trip which will take in Montana, Utah, Arizona and Tennessee to study modern practice at American copper mines and smelting works.

N. O. Lawton was in New York last week on professional business. He left Dec. 4 to examine and report on some mining properties, and will return to New York next week.

Dr. L. D. Ricketts and W. D. Thornton, vice-president of the Inspiration Consolidated Copper Co., have just completed an inspection tour of the property and of the International smeltery at Miami.

Dr. Charles R. Van Hise, the eminent geologist and president of the University of Wisconsin, is chairman of the commission appointed to investigate the slides in the Panama Canal and the probable causes.

Durward Copeland, professor of metallurgy at the School of Mines and Metallurgy of Missouri, sailed from New York Nov. 27 on the "St. Paul" for London, England, where he goes to make a study of the tin industry in Wales.

Edwin Higgins, engineer for the Bureau of Mines in the Lake Superior district, has been transferred to California, where he will take charge of the work for the bureau, which coöperates with the state in mine inspection work.

P. H. Mynahan, of Pittsburgh, formerly manager of the Louckes Iron and Steel Co., Roanoke, Va., is in Vancouver, B. C., engaged in the erection of a rolling mill for the Port Moody Steel Works Co., of which he has been appointed manager.

Benjamin B. Lawrence, a member of the class of '78, has purchased the Pelton-Doble water wheel and the Pelton-Francis turbine which were exhibited by the Pelton Water Wheel Co. at the Panama-Pacific Exposition, and has presented them to the Columbia School of Mines.

Herbert F. Black, who last week was elected a director of the Cambria Steel Co., has been with the Cambria company since 1912, in the capacity of ore agent, with offices at Pittsburgh. He is in charge of the production and shipment of materials entering into the manufacture of the company's products, including ore, coke, limestone, coal, ferromanganese, spiegel, etc.

OBITUARY

William Simpson Lyle died in San Francisco, Nov. 26, aged 78 years. He was born in Maine and went to California in 1852. He early began to invest in mines and owned many valuable properties. At one time has was associated with Clarence Mackay and James Fair. He was one of the earliest investors in Arizona mines.

Charles Edward Stafford died Nov. 27 at Haverford, Penn., aged 61 years. For many years Mr Stafford was chemist at the plant of the Pennsylvania Steel Co. He was widely known for his improvements in openhearth furnace design. From 1885 until 1896 he was manager of the steel department of the Shoenberger Steel Co., Pittsburgh. He was also connected with the South Chicago plant of the Illinois Steel Co., and at one time was president of the Tidewater Steel Co., at Thurlow.

John Shaw Scott died at Salt Lake City, Utah, Nov. 30, aged 87 years. Born in Massachusetts, he went to California when a young man and lived in San Francisco for 10 years. In 1871 he went to Utah, where he formed the firm of Scott & Anderson, samplers and ore buyers, which for a number of years owned the Johnson Sampling Works at Sandy, Utah. He also owned interests in many Utah mines, especially those at Alta.

Adolphe Greiner, managing director of the John Cockerill Works, the important steel and ordnance works of Belgium, at Seraing, near Liège, and president of the British Iron and Steel Institute, died Nov. 20. It is generally understood that he refused to comply with German demands with regard to the operation of the works when the Germans gained control of that part of Belgium in the fall of 1914 and for a time at least was practically a prisoner in his own house. According to the report of the council of the Institute, printed in its 1915 volume, he "remained at his post, continually encouraging with his unfailing spirit the members of the staff of the Cockerill company and his workmen, and organizing means for the alleviation of the distress of the large industrial population dependent on the company for employment." Doctor Greiner's elevation to the presidency of the Institute was announced at its meeting in September, 1913, in Brussels, and he assumed office at the meeting in London, in May, 1914. His notable presidential address had to do with coke ovens, coke-oven gas and coke-oven byproducts, and with blast furnaces, blast-furnace gas and slags, cements, bricks, etc. He was 71 years of age. Since 1887 he had been managing director of the Cockerill Works, but his whole business life was devoted to this company, which he entered in his youth as a chemist after training at Liège School of Mines. The company adopted the basic bessemer process under his directorship. He was a pioneer in the utilization of blast-furnace and coke-oven gases for the generation of power in iron and steel works. He was president of the Central Committee of Industrial Labor of Belgium, president of the Geological and Mining Society of Belgian Engineers and an officer of the Legion of Honor. He was also past president of the Society of Engineers and of the Société d'Ingenieurs Sortis de l'Ecole Polytechnique. He held the Bessemer medal of the Institute and was the second foreigner on whom the Institute's presidency has been conferred, the other being Andrew Carnegie.

SOCIETIES

National Rivers and Harbors Congress—At the 12th annual convention in Washington, D. C., Dec. 8-10, a moving picture will be shown depicting the iron ore industry on the Mesabi Range, dockage facilities and methods at Duluth, and the manufacture of the metal in Eastern furnaces and mills.

University of Illinois—The members of the senior class of the department of mining engineering, have returned from their annual inspection tour of mines, which was in charge of Prof. E. A. Holbrook. This year, through the courtesy of the various companies, studies were made at the mines and plants of the Paradise Coal Co., Duquoin; Old Ben Mining Co., West Frankfort; Chicago & Carterville Mining Co., Herrin; and Peabody Coal Co., Mine No. 3, Marion. Afterward the party visited the offices of the Western Coal and Mining Co., St. Louis, where the office end of coal mining was explained. Following this several days were spent studying the lead mines and concentrators of the St. Louis Smelting and Refining Co., St Francois, Mo.; St. Joseph Lead Co., Rivermines; and the Federal Lead Co., Flat River, Mo. The lead smeltery of the St. Louis Smelting and Refining Co., at Collinsville, Ill., was also visited. A similar trip is a yearly requirement for all students at the University expecting to receive the degree in mining engineering.

INDUSTRIAL NEWS

A series of three industrial motion-picture films, illustrating the manufacture of "National" pipe, from ore to finished product, will be shown before the Princeton Engineering Association at the Princeton Club, 121 East 21st St., New York City, Wednesday evening, Dec. 15, at 8:30 o'clock. No admission will be charged.

The Western Electric Co. has changed its Detroit headquarters from 263 Franklin St. to Kirby and Dequindre St. The new building is two stories high and has a frontage of 150 ft. and a depth of 130 ft. adjoining the Grand Trunk Ry.

in the section that forms a part of the inner belt railway of Detroit. The total floor space is 50,000 sq.ft., and the yard area 54,000 sq.ft.

The American Refractories Co., of Chicago, has leased the plant of the Buckeye Portland Cement Co. at Harper, Ohio, which is now being equipped and machinery installed for the calcination and production of dead burned magnesite on a large scale. Large tonnages of California magnesite have been purchased, and it is expected the plant will be in operation early in December. It will be run continuously until conditions in Europe permit a resumption of shipments from Austria.

The Russian Society for Electrical Enterprises, Ltd., 5 Marsowa Polje, Petrograd, which is the concessionaire for electric-lighting stations in Pawlowsk, Uman and Kamenetz-Podolsk and of tramways in Elizabethgrad and Uman, has opened a branch for resale of electrical machines and apparatus, and insulating materials, and also of steam and naphtha engines as well as of water-turbines, and desires to enter into relations with first-class factories in the United States producing these goods with the view of becoming their agents in Russia. The company belongs to the Russian and French Bank, and offers the complete guarantee of this bank.

On Dec. 1 the Buffalo Foundry and Machine Co. opened an office in New York City in the Whitehall Building, 17 Battery Place. The company manufactures vacuum dryers of all types, dry vacuum pumps, condensers, vacuum drying and impregnating apparatus, Buflokast chemical apparatus, including complete plants and apparatus for the manufacture of aniline, phenol, beta naphthol, picric acid, caustic soda, acids, chemicals and kindred organic materials and "Bell" steam hammers. It also does a general jobbing, foundry and machine business, and can quote on castings up to 200 tons in weight each, including all necessary pattern and machine work.

At the Chemists' Club, New York City, on Nov. 10, a dinner was held to discuss plans for the next National Exposition of Chemical Industries, at which the following were present: Raymond F. Bacon, Chas. H. Herty, Henry B. Faber, A. D. Little, E. F. Roeber, George D. Rosengarten, T. B. Wagner, L. H. Baekeland, M. C. Whitaker, B. C. Hesse, Adrian Nagelvoort and Chas. F. Roth. R. G. Hollaman and F. W. Payne, all of whom will serve on the Advisory Committee for the 1916 National Exposition of Chemical Industries to be held at the Grand Central Palace, New York City, week of Sept. 25, 1916. At this meeting Dr. Charles H. Herty was elected to serve as chairman of this committee for the coming year. Plans for enlarging and increasing the scope of this coming exposition were laid. The plans include using several floors of the Grand Central Palace, with speakers in the evening and motion pictures during the day from 11 a.m. to 7 p.m.

The Wheeler Condenser and Engineering Co., of Carteret, N. J., has just issued two booklets, "Psychrometric Tables for Cooling Tower Work" and "Steam Tables for Condenser Work." The former includes in its contents an introductory discussion on psychrometry and tables giving the dry- and wet-bulb thermometer readings with the corresponding dew point, percentage of humidity, and pounds of water per thousand cubic feet of air over a wide range of temperature, together with an appendix on the sling psychrometer, with directions for its use in obtaining dry- and wet-bulb thermometer readings. The second contains a table of properties of saturated steam from 29.8-in. vacuum to atmospheric pressure, and the properties of saturated steam from 32° F. to 212° F.; in a third table the properties of saturated steam from 0-lb. gage pressure to 200-lb. gage pressure; with an appendix on the use of the mercury column for measuring pressures. These are both well gotten up, and are for free distribution to interested engineers.

TRADE CATALOGS

M. Smolensky Mfg. Co., Cleveland, Ohio. Catalog, Suction and Check Valves. 16 pp., illus., 6x9 inches.

The Denver Engineering Works Co., Denver, Colo. Bulletin No. 1,076, Ball Mills. 8 pp., illus., 8½x10½ inches.

The James Leffel & Co., Springfield, Ohio. Catalog No. 65, Steam Engines and Boilers. 32 pp., illus., 8½x11 inches.

The Gardner Governor Co., Quincy, Ill. Pamphlet, "Helpful Hints on Air Compressor Installations. 8 pp., illus., 4x9 inches.

Richardson-Phenix Co., Milwaukee, Wis. Bulletin No. 50, Phenix Force Feed Lubricators. 12 pp., illus., 8½x11 in. Bulletin No. 60, Richardson Model M Sight Feed Oil Pump. 20 pp., illus., 8½x11 inches.

Arthur H. Thomas Co., West Washington Square, Philadelphia, Penn. Bulletins of Chemical Apparatus. Illus., inches.

The Dobbins Core Drill Co., Inc., Singer Bldg., 149 Broadway, New York, N. Y. Catalog No. 16, the Dobbins Core Drill. 46 pp., illus., 8½x5¼ inches.

Harrison Safety Boiler Works, Philadelphia, Penn. Pamphlet, "Finding and Stopping Waste in Modern Boiler Rooms by Use of Cochrane Meters." 68 pp., illus., 6x9 inches.

Allis-Chalmers Mfg. Co., Milwaukee, Wis. Bulletin No. 1,097, Power Transformers. 24 pp., illus., 8x10½ in. Bulletin No. 1,036, Hydraulic Turbines and Accessories. 56 pp., illus., 8x10½ in., Bulletin No. 1,801-A, Isbell Vanner. 22 pp., illus., 8x10½ inches.

NEW PATENTS

United States patent specifications listed below may be obtained from "The Engineering and Mining Journal" at 25c. each. British patents are supplied at 40c. each.

BLAST-FURNACE FLUE DUST—Pigment. Frank Orth, Indiana Harbor, Ind. (U. S. No. 1,161,790; Nov. 23, 1915.)

COATING IRON AND STEEL SHEETS with Lead and Lead Alloys. Reginald Hazeltine, Wheeling, W. Va., assignor to Wheeling Corrugating Co., Wheeling, W. Va. (U. S. No. 1,161,475; Nov. 23, 1915.)

DRILLING MACHINE. Mather W. Sherwood, Franklin, Penn., assignor to Chicago Pneumatic Tool Co., Chicago, Ill. (U. S. No. 1,161,259; Nov. 23, 1915.)

DRILLS—Means for Mounting Rock Drills. Otto Stuhaug Tonnesen, Johannesburg, Transvaal. (U. S. No. 1,160,672; Nov. 16, 1915.)

ELECTRIC FURNACE. Alex Dow, Detroit, Mich. (U. S. No. 1,161,634; Nov. 23, 1915.)

ELECTRIC FURNACES—Treating Materials in Electric Furnaces. Edward Salomon Berglund, Trollhattan, Sweden. (U. S. No. 1,160,244; Nov. 16, 1915.)

EXPLOSIVES—Apparatus for Testing Mining Powder. Francis I. du Pont, Wilmington, Del., assignor, by direct and mesne assignments, to Ball Grain Explosives Co., Wilmington, Del. (U. S. No. 1,161,462; Nov. 23, 1915.)

FUEL—Comminuted-Fuel Feeder. John F. Hay, Erie, Penn. (U. S. No. 1,160,283; Nov. 16, 1915.)

HOT-BLAST STOVE. Thomas Coultas and Thomas I. Coultas, Pittsburgh, Penn. (U. S. No. 1,161,031; Nov. 23, 1915.)

LAMP—Portable Acetylene Lamp. Augie L. Hansen, Evanston, Ill., assignor to Justrite Manufacturing Co., Chicago, Ill. (U. S. No. 1,161,209; Nov. 23, 1915.)

LIQUID-FLOW MEASUREMENT—Balancing and Measuring Apparatus. George H. Gibson, Montclair, N. J., assignor to Joseph S. Lovering Whalton, William S. Hallowell, and John C. Jones, Philadelphia, Penn., a firm doing business as Harrison Safety Boiler Works. (U. S. No. 1,160,275; Nov. 16, 1915.)

MAGNETIC ORE SEPARATOR. Samuel N. Smith, New York, N. Y., assignor of one-half to Herman W. Hoops, New York, N. Y. (U. S. No. 1,161,351; Nov. 23, 1915.)

NITROGEN COMPOUNDS—Method for Producing Nitrogen Compounds. Charles E. Acker, Ossining, N. Y., assignor to The Nitrogen Co. (U. S. No. 1,160,811; Nov. 16, 1915.)

PHOSPHATE—Method of Drying and Enriching Phosphate Material and the Like. Maximilian Mattheus Haff and Thomas Leopold Willson, Ottawa, Ont., Canada, assignors, by direct and mesne assignments, to Southern Investment Co. of Canada Ltd., Montreal, Canada (U. S. No. 1,161,473; Nov. 23, 1915.)

PNEUMATIC TOOLS—Handle and Inlet-Controlling-Valve Construction for Pneumatic Tools. Francis A. Jimerson, Athens, Penn., assignor to Ingersoll-Rand Co., Jersey City, N. J. (U. S. No. 1,160,617; Nov. 16, 1915.)

POTASSIUM SULPHATE—Process of Producing Potassium Sulphate. George S. Morgan, Toledo, Ohio. (U. S. No. 1,161,239; Nov. 23, 1915.)

REDUCTION—Method of Reducing Metals. John Woods Beckman, Berkeley, Calif. (U. S. No. 1,160,822; Nov. 16, 1915.)

SAFETY GLASSES—Eye-Shield Protecting Spectacles. Frederick Willson and Numa Bourquin, Reading, Penn., assignors to T. A. Willson & Co., Inc., Reading, Penn. (U. S. No. 1,161,166; Nov. 23, 1915.)

SLAG—Means for Utilizing the Heat of Molten Slag. Ralph Baggaley, Pittsburgh, Penn. (U. S. No. 1,160,817; Nov. 16, 1915.)

SMELTING—Method of Smelting and Incinerating. William R. Heslewood, Oakland, Cal., assignor, by mesne assignments, to Hydro Vacuum Smelting Co., Oakland, Calif. (U. S. 1,160,509; Nov. 16, 1915.)

SMELTING—Process of Smelting Ores. John H. Klepinger, Milo W. Krejci, and Charles R. Kusell, Great Falls, Mont. (U. S. No. 1,160,621; Nov. 16, 1915.)

SODIUM ALLOYS—Electrolytic Production of Sodium Alloys. Edgar Arthur Ashcroft, London, England. (U. S. No. 1,161,585; Nov. 23, 1915.)

STACK—Transversely-Bracing and Interlocking Hot-Air Stack of Rectangular Cross-Section. Albert G. Scherer, Chicago, Ill., assignor to The Excelsior Steel Furnace Co., Chicago, Ill. (U. S. No. 1,160,202; Nov. 16, 1915.)

TIN—Electrolytic Process of Detinning. Hans Goldschmidt, Essen-on-the-Ruhr, Germany, assignor to Goldschmidt Detinning Co., New York, N. Y. (U. S. Nos. 1,160,400 and 1,160,401; Nov. 16, 1915.)

Editorial Correspondence

SAN FRANCISCO—Dec. 1

Silver-Producing Camps in California and Nevada are encouraged to a point of enthusiasm by the rise in the price of silver. The recent strikes of high-grade ore in the Comstock mines and the continued development of ore of high value together with the price of silver, puts the Comstock in the best position that it has been for a number of years. Mining men from Tonopah and Virginia City declare that the production of those camps will be doubled in case the price of silver is maintained at the high figure now quoted. The principal silver-producing mines in California are in Shasta, Inyo, Calaveras, San Bernardino, Nevada, Amador and Tuolumne counties. Other counties producing silver and capable of increased production to an appreciable amount are Imperial, Kern, Mono and Yuba.

The Oil Industry Association, recently organized, is making strong efforts to induce the Government to withhold the filing of further withdrawal or other legal actions against operators of oil land in California, pending remedial action by Congress. There are 25 suits now pending in the U. S. Courts. In most cases receivers have been appointed. The filing and hearing of such suits has become so common as to attract but little attention outside the oil industries. The proposition of withdrawal of oil lands is obviously to conserve the oil in place for the benefit of the U. S. Navy. Two such Naval reservations have been made in the California oil fields, one of which embraces 30,000 acres of undeveloped land. In these cases the oil measures may be conserved without detriment to adjoining land; but to shut in fields developed by private enterprise and conserve such ground for the benefit of the Government would mean the loss of the oil instead of conservation of it, because such developed lands would be drained by adjoining operations, in most of the cases where the Government has brought suit. The enterprise and expenditures of oil men has made it possible in many instances for the Government to select undeveloped land. From such fields the Government can secure sufficient conservation for Naval supply. In one of these suits it was shown in the evidence that the operators had expended approximately $20,000 in sinking wells from March till January, 1909; and because they suspended work in August and did not resume until January, 1910, it would appear that the Government must take the land away from them and conserve it to the uses of the Navy. The interested oil men are slightly encouraged by the recent expression of Secretary Lane, that if the full measure of the Government rights is acted upon it will bankrupt many oil companies and do unnecessary injustice to men who have invested millions of dollars under a mistake as to the law. He believes that Congress should so act as to recognize the equitable rights of such operators. Secretary Lane offers no remedy, but merely says what might be done, then declaring that such plan is too liberal. What he suggests as might be done is that those who would today be entitled to patent, were the land not withdrawn, might have leases under which they will pay a liberal royalty to the Government.

BUTTE—Nov. 30

The City of Butte Will Be Compelled to Pay the damages sustained by property owners and business men who suffered loss when Miners' Union hall was dynamited on the night of June 23, 1914. In the District Court Judge Lynch instructed the jury to that effect in the case of Thomas Duffy, who had a saloon in the Miners' Union hall building at the time of the dynamiting. He had brought suit against the city of Butte for $7,100 to reimburse him for losses sustained when the enemies of the old Butte Miners' Union No. 1, attacked the hall and wrecked the building.

The Advance in the Price of Silver from 48c. per oz. to 56c. per oz. within a week's time has resulted in a boom in all of the north and west Butte districts. Fully 200 leasers have secured options on claims in the so-called silver district and are already beginning operations. Many of the abandoned mines are showing renewed life. If silver continues to rise in price and should go above 60c. per oz., silver production will easily be increased to 2,000,000 oz. per month. The Nettie mine in the western district which is now being unwatered has vast quantities of ore that runs high in silver. By the first of the year the Anaconda company will have this mine almost in readiness for operation. The Hibernia and other silver-mining properties close to it will probably be started soon after the Nettie resumes. W. A. Clark's new shaft at the Eveline is being sunk rapidly and this will open up some valuable silver-zinc orebodies, according to the expectations of the engineers who passed upon the property. Not since the early '90s has the activity in the silver properties been so great as at present.

DENVER—Dec. 2

Tungsten Has Been Known as one of the Silverton district's minerals for years, but no important effort to market the material was ever attempted until the recent advance in the market made the idea attractive. The new Colorado Metal Co. has rented the Yukon mill, on Cement Creek, and will use it to concentrate its ore from the Dawn of Day mine near Gladstone.

Cripple Creek's Total Production during November is placed at 82,830 tons of an average gross value of $15.66 per ton; the gross bullion value being $1,297,441. As usual, the great Golden Cycle plant at Colorado City handled far more than any other mill or smeltery, its tonnage for November being 37,500 or at the rate of 1,250 tons daily. The Portland mill at the same place treated 11,000 tons. The two Portland mills in the district are credited with the treatment of 27,500 tons of ore running $2.50 to $3 per ton.

SALT LAKE CITY—Dec. 3

The Utah Metal and Tunnel Co. of Bingham has taken formal possession of the Bingham-New Haven Copper and Gold Mining Co.'s property adjoining. The capitalization of the Utah Metal has been increased by 225,000 shares, the present authorized capitalization being 725,000 shares; the increase is to be used to take up the Bingham-New Haven shares. Before the increase there were 463,128 shares outstanding and 36,872 shares in the treasury. The company has a bonded indebtedness of $359,500, which it assumed when it took over the Bingham Central Standard ground. A final dividend of 20c. a share is being distributed by the Bingham-New Haven, amounting to $43,738. There will still remain $250,000 cash in the treasury, which will go with the property. The Bingham-New Haven stockholders will receive share for share of the Utah Metal stock. For the present the two companies will be operated separately, with E. P. Jennings and W. A. Barnes in charge of the Utah Metal end, and C. H. Doolittle, general manager of the Bingham-New Haven in charge of that end of the property. The work of the two companies will be gradually merged. W. E. L. Dillaway, secretary and treasurer of the company has been here looking over the affairs of both companies, and working out the details of consolidation. Shipments from the Bingham-New Haven at present amount to 230 tons of ore and concentrates a day. The company is milling 130 tons. The Utah Metal is shipping 110 tons a day, and it is hoped to have the combined output of the two companies up to 400 tons a day soon. The Bingham-New Haven ores are being shipped over the Utah Consolidated tramway to the International smeltery under a favorable contract, with several years still to run, and shipments from this end will be continued as heretofore. The Utah Metal end has been making arrangements for the extension of a railroad spur to its ore bins, which will cut out the half-mile wagon-haul down to the Utah Apex siding. This would mean a saving of upward of $10,000 a year. The orebodies in the two properties are closely associated, a recent strike of copper ore in the Bingham-New Haven making over into Utah Metal ground, and the large orebody in the Utah Metal being close to the line. The consolidation will be of benefit to all concerned, and will prevent possible litigation.

WALLACE, IDAHO—Nov. 30

The Bunker Hill & Sullivan company is still "up in the air" with respect to the location of the smeltery. With satisfactory freight rates there appears to be no doubt that it will be located adjacent to the mine at Kellogg. It is understood that the management prefers Kellogg, and will place the plant there unless there is too great a disparity in the bullion freight rate between Kellogg and the coast. Strong pressure is being brought to bear to secure a favorable rate for Kellogg, and in this the business men of Spokane are heartily coöperating. It may be several weeks before the question is settled, but it looks like Kellogg.

DULUTH—Dec. 4

Navigation Will Close at the Head of the Lakes on Dec. 6. Every dock but the Great Northern showed a substantial increase over 1914. The following tonnage figures are subject to slight corrections, but are substantially correct.

Dock	1915	1914
D., M. & N.	15,437,419	6,318,295
D. & I. R.	8,642,942	5,579,929
N. P.	173,047	137,664
Northwestern (Ashland)	4,134,000	2,605,275
Soo (Superior, Wis.)	960,595	721,662
Soo (Ashland, Wis.)	1,012,773	758,144
	30,360,776	16,120,969

The docks at Marquette and Escanaba, Mich., will continue shipping for another week, which prevents securing grand total of tonnage at this time.

Litigation Is Expected as a result of a recent decision by the U. S. Supreme Court that the natural channel of the St. Louis River was the boundary between Minnesota and Wisconsin. The large modern coal docks of the Carnegie Coal Co. and the Zenith Coal Co., on the Minnesota side, extend beyond this line as originally surveyed. Litigation is now expected wherein the property owners on the Wisconsin side opposite will claim ownership of the ends of these docks, because of riparian rights from the water line to the center of the channel.

The Railroads that Haul Iron Ore from the Minnesota ranges to the docks at the head of Lake Superior are figuring on a greatly increased tonnage next season. Heavy orders are being placed for rolling stock. Cars were greatly in demand this year, but it is predicted that 1916 will be the banner year in the iron-ore trade, and every ton of ore that the boats can handle will be taken down to lower lake ports. The Duluth, Missabe & Northern road placed orders this week for two grade-climbing Mallet compound locomotives, six locomotives of the Santa Fé type, similar to those used on that road's mountain division, 1,000 steel hopper ore cars and 200 steel hopper coal cars. The ore cars will be furnished by the Western Steel Car and Foundry Co., of Hegewison, Wis., and the Pullman Car Co. will make the coal cars. The Duluth & Iron Range road has ordered 750 steel hopper ore cars from the American Car and Foundry Co. and the Standard Steel Car Co., and three Mikado locomotives for heavy freight service. One new dock is to be erected at Two Harbors by the Duluth & Iron Range road, as there is not storage space enough at the present time to take care of any great tonnage. One of the old wooden docks will be torn down and replaced by a larger one of steel and concrete. Considerable money will be spent by the Missabe road in improving and increasing the road's terminals at Proctor, and putting in additional track scales, which will be needed to meet the demand. The year 1916 is going to be an interesting one for the iron ore operators, the railroads and the boat lines, as there will be increased rates for hauling for the lake carriers, and the mining companies expect to receive at least 75c. more for their product than they have been getting the last two years.

GLOBE, ARIZ.—Nov. 30

Asbestos Mining on Ash Creek, 40 mi. northeast of Globe, is on the increase. The best-developed property is that of Fisk and Snell who have just completed a mill and are preparing to extract asbestos on a large scale. Altogether 3,400 ft. of development work has been done. Shipments averaging one ton per day have been going out on burros to Globe and to Rice on the Arizona Eastern R.R. Another property, part of which adjoins the Fisk and Snell claims and in which H. Kenyon Burch is said to be interested is to be opened up; work is scheduled to start next week.

A Shipment of Tungsten Ore was recently sent to the Primos Chemical Co. by Victor Jackson, who is leasing on the claims of the Powers Gulch Development Co. Jackson was employed to do assessment work on the company's property of 22 claims on the Gila and Pinal County line. He recognized as tungsten ore what had formerly been mistaken for rich copper ore and sent a sample to the Primos company which sent a representative to the property with the result that 831 lb. recently shipped brought $559 less freight. In all 2,000 ft. of development work has been done on the property; one shaft having been sunk to a depth of 104 ft. and another to 176 ft.

Work on Prospects in the Globe District on the eastern slope and foot-hills of the Pinal Mountains southeast of Globe has aroused no little interest locally, as important discoveries of gold-copper ore have been made. On one of these a shaft has been sunk to a depth of 26 ft. in ore averaging $17 per ton in gold, in another some $100 gold ore has been found, but the vein, which is between diorite and schist, carries copper as the chief metal. In one of these properties, the Logan, 2,000 ft. of development work has been done and some high-grade copper ore carrying about $8 gold is to be taken out for shipment to the smelter. The low-grade is of commercial concentrating ore. Gold ore is being mined by lessees on the southwestern slope of the Dripping Springs range south of Hayden. The low-grade ore assays $16 per ton but some of the leasers have run across a little high-grade specimen ore that runs up to $8,000 or $10,000. The vein is exposed in the hill and highgrade is found at depth.

The Christmas Mine a few miles above Winkelman will become an important producer by the first of the year. Christmas is now the terminal of the Phœnix & Arizona Eastern R.R., connections with Globe being made by auto-stage three times weekly. A small tonnage of ore is now being shipped regularly to the smeltery at Hayden; most of it being produced by leasers who are gophering into the hill along the outcrop of the load and transporting the ore down to the railroad terminus by burro. The Christmas mine was acquired by the A. S. & R. Co. this summer and is being put in condition for regular production, when 250 to 300 men will be employed. The work for the last few months has comprised building an ore pocket at the railroad terminus and another with crushing machinery just east of the main shaft; a wire-rope aërial tram, 7,000 ft. long, connecting the mine pocket with that at the railroad. The track cables have just been strung and when in operation it is calculated that about 25 hp. will be developed in excess. Electric power will be brought in from Hayden. The ore is bornite, chalcocite, chalcopyrite and pyrite in a garnetiferous gangue; the deposit being in a contact of limestone with granitic-porphyry. The orebody is wide and persistent with prominent outcrops and is said to be well developed down to a depth of 800 ft. The work is being done under the supervision of S. H. Sherman, who has been connected with the property for several years. The property was one time owned by the Saddle Mountain Mining Co. in which New Haven people were interested and by the Gila Copper Sulphide Corporation.

HIBBING, MINN.—Nov. 27

Tax Dispute between the mining companies and village officials was amicably adjusted on Nov. 23 at a conference in the city hall. The mining companies are to pay their taxes in cash within three weeks, except that they may pay in one-half of the village water-works warrants which they now hold. In return, the village is to limit its expenditures to $24,500 per month, except as to payments on certain outstanding contracts, or emergency expenditures. All litigation between the village and mining companies is to be abandoned. The proposed $1,900,000 tax levy for 1916 is likewise to be abandoned.

METALINE, WASH.—Nov. 30

Activity in the District is slowing up on account of the season, but prospects are that there will be a considerable amount of work undertaken in the spring. At present the Metaline Oriole Co. has started work in the lower tunnel to drive to the ore which was cut off by a fault. The Milwaukee Ltd., is asking for bids for 100 ft. of tunnel work, which it expects will cut the main vein. The Lead and Zinc Co. is working 25 men. The mill has been enlarged and is now awaiting the arrival of new machinery. It expects to be running at full capacity by the end of the year. The Riverside property is surveying its ground for a patent.

ATLANTA, IDAHO—Nov. 23

Considerable Activity, considering the handicap, is noted in the Atlanta district. The Boise-Rochester, which took over all the old Bagdad-Chase property, including 40-stamp mill, power plant, tram line, etc., has acquired additional ground—Old Chunk and Webfoot claims. The mill is dropping 20 stamps; the remaining 20 will be operated as soon as sufficient ore is blocked out. T. C. Brown, inventor of the Pachuca tank, has charge of the mill and is erecting an experimental cyanide plant to handle the concentrates. If this proves successful, the plant will be altered next summer to an all-slime cyanide mill. The ores of this district have been difficult to treat, and many failures have been made. The ore averages about $10, of which about 60% is saved by amalgamation, 20% on the concentrators, and 20% goes into the tails. The camp is handicapped by being 80 mi. from the railroad, and wagon roads over the mountains are closed six to seven months a year; the freight rate is $40 per ton when the roads are good. The district is in a forest reserve, and the Government exacts payment of 1c. per ft. for timber, 1c. apiece for lagging, $2.50 per M for lumber, and 65c. per cord for wood, for all such material used. The veins of the district are all soft, and close timbering is required, so that these fees to the Government seem to be a hardship to the miner. The Overlook Mining Co., 16 mi. from Atlanta, is installing a 10-stamp mill, Bleichert tramway, etc. S. A. Work is superintendent. Twenty-five men are working there.

The Mining News

ALASKA

ALASKA MEXICAN (Treadwell)—During October crushed 19,075 tons. Total yield per ton of ore milled, $1.43.

ALASKA TREADWELL (Treadwell)—During October crushed 82,593 tons of ore. Estimated gross realizable value $153,415.

ALASKA GOLD BELT (Juneau)—Face of tunnel was in 2,300 ft. on Nov. 26. Main orebody is expected to be cut at 2,500 ft.

ALASKA UNITED (Treadwell)—Started up 30-stamp addition to R. B. mill, Oct. 24. During October R. B. mill crushed 22,848 tons of ore and 700-Ft. mill 23,170 tons. Yield per ton of ore milled, $1.84 and $1.30 respectively.

ARIZONA

Cochise County

MASCOT COPPER (Mascot)—Shipped 1,256 tons of ore to smelters in October. Company has ordered new consolidation Baldwin locomotive.

CARTWRIGHT MINES (Johnson)—Virginia-Arizona Copper and Smelting Co. organization of Douglas men, has acquired Cartwright group in Winchester district southwest of Johnson.

MILLER CAÑON (Hereford)—News of a gold strike Saturday, Nov. 27, precipitated somewhat of a rush for this district. Miller Cañon is situated in the Huachuca mountains, few miles south of Hereford, and was located as placer ground.

Gila County

ARIZONA COMMERCIAL (Globe)—Reported to have decided to erect $50,000 power plant and discontinue using Old Dominion power.

NEW KEYSTONE COPPER CO. (Miami)—Company has now been dissolved. Distribution of 93c. per share upon outstanding stock of the company of the par value of $1 per share has been declared in full and final distribution of assets of company.

Greenlee County

THE FEDERAL INVESTIGATORS in the Clifton-Morenci-Metcalf strike district, Messrs. Davies and Myers, have completed their work after taking many affidavits at the three camps.

Maricopa County

MAX DELTA (Phœnix)—Plans to build mill at mine, 9 mi. south of Phœnix. Former United States Senator Lee Mantle, of Butte, Mont., is president.

Mohave County

TOM REED MINE (Kingman)—Cleaned up $100,000 in October.

GOLCONDA (Kingman)—Is now working 265 men and producing $250,000 monthly.

GOLD ROAD BONANZA (Gold Road)—Work has been started on 2-compartment shaft, to be sunk 200 ft.

COPPERFIELD (Mineral Park)—Copperfield Porphyry Copper Co. incorporated to develop 120 acres around Ithaca Peak.

NELLIE MINING CO. (Kingman)—Contract has been let for 4½x8x500-ft. shaft. Automobile road to property is being built.

SILVER & BIG BETHEL (Kingman)—Situated on Golconda vein. Has been sold to C. B. Bell and associates of Douglas.

MAZONA MINING CO. (Oatman)—Will start sinking 500-ft. vertical shaft upon its group of nine claims, adjoining Tom Reed and Gold Cliff mines on west.

SHOOTING STAR (Chloride)—Kingman Zinc Mining Co. has taken over Fountaine, Cupel, Robinhood and Shooting Star mines in the Stockton Hill district of Cerbat.

OATMAN BIG LODE MINES CO. (Oatman)—Preparing to start development work upon a group of six claims which it has acquired from D. P. Mitchell and associates.

CARTER M. & M. (Kingman)—Proposed 500-ft. shaft now down 250 ft. A 4-ft. vein assaying $14 was discovered in winze 20 ft. from southeast drift on 150-ft. level.

GOLD ORE (Gold Road)—Drifting on 500 level is being pushed. Thirteen feet of $40 ore has been encountered in east drift and 9-ft. vein assaying $100 has been found in tunnel going west.

OATMAN SECRET GOLD MINING CO. (Oatman)—Composed of prominent Arizona men, has just been organized to take over Gold Coin group. Wagon road to property is being constructed and bunk and cook houses are being built. A 50-ft. shaft will be sunk immediately.

OATMAN SYNDICATE MINING CO. (Oatman)—J. Parke Channing, consulting engineer of the Adolph Lewisohn interests, of New York, and associates have organized the Oatman Syndicate Mining Co., which has taken over the Putney group of 12 claims belonging to H. G. Putney, in Oatman district. A 500-ft. vertical shaft will be sunk and other development work done.

UNION BASIN (Golconda)—Expects to finish construction of 200-ton flotation plant about middle of next month. Its new high-tension electric-transmission line being built from Kingman to the Golconda mine, 20 mi., will be finished about same time. Controlling interest in the company is owned by N. L. Amster, of Boston, Mass., and associates. Mine is now producing between $200,000 and $250,000 gross, monthly. Main shaft has reached 900-ft. depth and station is now being cut.

Pima County

STRATTON COPPER CO. (Tucson)—Plans to build new concentrator at its mines in Catalina Mountains. Will have daily capacity of 500 tons.

PIONEER SMELTING (Corwin)—By a ruling of the state supreme court upholding Pima County Superior Court, Messrs. Walker, Zipf and Dickson, trustees in bankruptcy of the Pioneer Smelting Co., recovered on note for $31,000 and foreclosure on some mining claims.

Yavapai County

PORTLAND ARIZONA (Copper Basin)—Preparations being made to install large compressor.

COPPER CHIEF (Jerome)—Hayden Development Co. is erecting 200-ton mill. Reported 500,000 tons ore blocked out.

HÜBNERITE has been found in Eureka district. Claims adjoin holdings of Lawler, Wood and Connor, who have already made shipments of this ore.

PEAU COPPER (Prescott)—A. L. Garford, automobile manufacturer, has bought controlling interest in this mine in the Cherry Creek district and has let contract for much exploration.

RANDOLPH-GEMMILL DEVELOPMENT (Crown King)—Reported to be successfully treating refractory ores of that district. Milling 100 tons daily of old Crown King dump on lease. Will enlarge plant to treat custom ore.

MERRILL METALLURGICAL CO. (Prescott)—Negotiations for sale of Congress gold mine by Development Co. of America to Merrill Metallurgical Co. of San Francisco practically closed. Extensive dump is to be treated.

UNITED VERDE EXTENSION (Jerome)—Producing 40 tons daily, of which 10 tons average about 45% copper. Eighty men employed. Hoist being installed to handle ore from 1,400-ft. level and work is progressing on new tramway to supplant burro transportation from mines to railroad.

BROOKSHIRE (Jerome)—Green Monster Mining Co. has been organized to take over Brookshire, Treadwell, Layman and Clark-Hopkins groups in Jerome district. Consolidation embraces 30 patented and 26 unpatented claims, lying between United Verde and United Verde Extension. Identified with new company are N. E. Bailey, superintendent of United Verde & Pacific; Leroy Anderson, attorney for United Verde, and Thomas Taylor.

CALIFORNIA

Contra Costa County

VALLEY PIPE LINE (Martinez)—New line completed, extending from oil fields at Coliola, Shell tank farm, a distance of 157 mi. to Martinez. Capacity of line, 25,000 bbl. per 24 hr. Expected that this line will supply demand of refinery. Shell company has installed 35 additional 55,000-bbl. tanks, to increase storage capacity at refinery.

Butte County

JOSEPHINE-BUMBLEBEE (Oroville)—Preparations being made for development and extraction of ore. Installation of new mill of 25 tons' capacity contemplated; machine drills will be installed.

Calaveras County

SUMMERVILLE (Angels Camp)—New shaft will be deepened to 800 ft. Overhauling 40-stamp mill.

SOMMERVILLE (Angels Camp)—New shaft near Forth crossing is down 130 ft. Property former producer. The 40-stamp mill is being overhauled. Old 800-ft. shaft has been abandoned.

Imperial County

NEW LIVERPOOL SALT CO.—Claim against California Development Co. is under option to Imperial Irrigation district, El Centro. Terms are $600,000 in bonds.

MODOC MINES (Highgrade)—N. E. Guyot, manager, is getting in winter supplies. Drift at 200 level has encountered vein which was disclosed on 100 level. Shaft will be deepened to 300 ft.

Inyo County

KEANE WONDER (via Rhyolite, Nev.)—Property has just come into possession of its new owners: Francis-Mohawk Mining and Leasing Co. of Goldfield, Nev.; F. L. Wildes, receiver of State Bank and Trust Co.; and E. F. Tatem, of Montana. Property was sold in November, 1914, to satisfy judgment. Equipment consists of 20-stamp mill, cyanide plant, and aërial tram mine to mill. Operations are to be resumed.

Mono County

PITTSBURG-LIBERTY (Masonic)—Mill operating full capacity on ore, chiefly from Golden Serita where good ore has been disclosed on 100 level. Some high-grade with milling ore. Development in Pittsburg-Liberty mine progressing satisfactorily. New York claim has been acquired by J. D. Martin and development started.

Nevada County

BLACK BEAR (Grass Valley)—New compressor and air pump of 300-gal. capacity being installed.

CONLIN (Grass Valley)—Alfred B. Swinerton, R. M. Hotaling and others, of San Francisco, have examined and are reported to have begun negotiations for purchase of property. Mine was formerly producer of high-grade ore.

COLUMBIA (Washington)—Ten-stamp mill crushing 50 tons of ore per day. Large amount of ore blocked out and reserve broken down. Compressed-air drills are used in drifts. Mine will operate all winter regardless of weather.

POLAR STAR (Grass Valley)—Ten men are employed and number will be increased as soon as living quarters are provided. Electric hoist and pump about ready for installation. Property adjoins North Star. Salt Lake men are operating. Oscar Coffine is superintendent.

EXCELSIOR (Forest Hill)—Second unit of three stamps has been added to mill and third is in course of construction in San Francisco. Reported that mill is crushing 100 tons of ore per day. New office building and five new residences have been built, giving camp a prosperous appearance.

OCEAN STAR (Washington)—Property which is owned by Englishmen will be reopened, with N. M. Melrose superintendent. Winter supplies have been ordered and development started. Recent financial difficulties said to have been adjusted to permit resumption of work. Shaft will be deepened and mill capacity increased.

Plumas County

ENGELS (Taylorsville)—Preliminary railroad survey on mine to Western Pacific R.R. about completed.

NEW YORK (Greenville)—Work in No. 3 crosscut will be renewed and extended until the vein is encountered.

STAUFER (Greenville)—Superintendent Elliott reports everything in readiness for winter work and probability of extensive development.

Sierra County

SOUTH FORK (Downieville)—Mason gravel claims bonded to Thomas Wilson of Manhattan, representing a Nevada company, who will soon begin active work.

MONARCH (Sierra City)—Richest and most important strike in 20 years in Sierra City district recently made here. Ore averages thousands of dollars per ton gold. This mine is on serpentine belt on which old and rich Sierra Buttes mine is located, and is being developed by R. G. Gillespie, of Pittsburgh, Penn. Extensive surface and power plant built during past year. Large restraining dam being built to hold tailings, and all preparations for continuous work on large scale at both mines during winter. D. McGonigal, superintendent.

Shasta County

REID (Redding)—New vein reported on 700 level. If ore proves to be medium grade, preparations will be made for extensive development, as orebody is said to be large.

ELDORADO (French Gulch)—James Connor, owner of this mine on Clear Creek near Tower house, is mining high-grade ore and treating it in two-stamp mill. Last cleanup returned $400 from 10 days' run.

HAY FORK VALLEY DREDGING GROUND reported at Weaverville to have been bonded to G. E. Hunter. There is large acreage in valley and it is believed that good proportion of it will prove valuable for dredging.

GLADSTONE (French Gulch)—Reported that ledge which was lost on 1,200 level has just been disclosed on 1,300 level. Number of men reduced in September, 75 being laid off and 32 retained to carry on drifting on 1,300 level. Gladstone is one of large producers of state and within past year or so has made important improvements including a steel headframe. J. A. Jilson, manager, and Edward L. Young, superintendent, were both confident that orebody would persist to and below 1,300 level.

GOLDEN JUBILEE (Carrville)—Mine taken over by California Extracting Co. of San Francisco. Purchase price said to be $50,000. Mine was located in 1896 and developed into good producer. Ores near surface were free-milling, but at depth refractory sulphides were encountered. Recently 40-ton cyanide plant was installed. Property was owned chiefly by Mcormick-Saeltzer Co. of Redding. Present operators contemplate installation of a tube mill and adoption of Vandercook process.

COLORADO

Clear Creek County

ONEIDA (Freeland)—Body of rich gray-copper ore has been opened in raise extended to height of 150 ft. at point about 1,000 ft. from portal of the Stag tunnel. Last 25 ft. of raise is in ore. Vein is 5 ft. wide and assays 0.52 oz. gold, 10 oz. silver and 4% lead.

UNITED FREELAND DEVELOPMENT AND TUNNEL CO. (Idaho Springs)—Property of this company, embracing over 100 patented lode mining claims and several millsites and tunnel sites, has been purchased by syndicate of Chicago and St. Louis capitalists, who have planned campaign of extensive development through McClelland tunnel. Portal of tunnel is located about 5 mi. west of Idaho Springs and one mile east of Dumont. Tunnel is now 7,150 ft. long. New company plans advance of 3,000 ft. to develop Freeland and Lamartine districts. Connection will be made with old Freeland shaft and workings will be drained. This connection will require 1,100 ft. of tunnel and 1,000 ft. of raising. It is probable that Lamartine, Gum Tree, Oneida, Lone Tree and Freeland Extension properties will all be benefited by new development Company contemplates construction of a modern milling plant at portal of tunnel, for treating its own ores and product of properties tributary to tunnel. L. W. Shaffer, of Idaho Springs, has been appointed general manager.

Lake County

DOWNTOWN PUMPING CO. (Leadville)—Has experienced provoking delays due to motor troubles, centrifugal pumping units having been idle at intervals that permitted heavy flow of water into old workings of Penrose and neighboring mines to gain appreciably on unwatering operations.

Ouray County

CAMP BIRD, LTD. (Ouray)—In October crushed 5,730 tons ore; estimated profit, £11,500.

IDAHO

Shoshone County

HECTOR (Wallace)—Long crosscut expected to cut vein 3 miles from portal has reached position vertically below outcrop, depth of 1,800 ft.

INTERSTATE-CALLAHAN (Wallace)—Judge Dietrich of Federal court has issued order discharging receiver appointed by Judge Woods of state court for this company.

BROWN & FINNELL (Pine Creek)—Operators have bonded Pine Creek antimony property to Burke McIntosh and associates, of Kellogg. New owners plan mill to treat entire mine output.

CLIMAX (Wallace)—Building has been erected for 10x10 compressor and 35-hp. motor, which will be installed at once, contract having been made with Washington Water Power Co. for current.

NATIONAL (Mullan)—National mill started Nov. 11. Only one shift is being worked now. National ore is low-grade copper, average probably not exceeding 2%, but carries considerable silver. Large amount of ore blocked out.

TAMARACK-CUSTER (Wallace)—Reports emanating from reliable sources, state that Tamarack-Custer is negotiating with Ray-Jefferson company to join in construction of mill to treat output of both properties, which lie near each other in Nine-Mile district of Coeur d'Alenes.

GETTYSBURG (Mullan)—Official statement from W. E. Cullen, secretary Independence Lead Mines Co., who is also secretary of the Stewart Mining Co., reports work concentrated on No. 4 tunnel of Gettysburg, from which raise will be made to No. 3, in which there is large body of lead ore. This is known as Gettysburg vein, extension of You Like. No. 4 tunnel also being extended to cut Morning vein.

MICHIGAN

Copper

COPPER PRODUCTION from the mines of the Michigan district ran close to 25,000,000 lb. for the month of November, and for December the product will be over 23,000,000 lb. refined, if the present basis of operation is maintained. Production for the Lake Superior district for the present year is estimated at more than 250,000,000 lb. The average price for the year will be above 16c.

AHMEEK (Kearsage)—Is producing larger tonnage of copper rock than ever before in its history and percentage of copper content is above average for Kearsarge formation, although not quite up to last year or year before for Ahmeek. Mill now is operating six heads and handling an average of 100,000 tons of copper rock each month, so that production is at rate of about 25,000,000 lb. per year.

CALUMET & HECLA (Hubbell)—Third of large furnaces for smelting plant at Hubbell now under construction. Work will be continued during winter. New furnace will have capacity of 150,000 lb. and will have electric equipment for loading and dumping. It is modeled after No. 20 and No. 21, each of which has capacity of 150,000 lb. The C. & H. smelting and refining plants now have payroll of 500 men, twice what it was year ago.

Iron

ODGERS (Crystal Falls)—Shaft sinking was started this week.

L. S. & I. RY. (Marquette)—Four new locomotives are to be ordered for ore hauling.

PIONEER IRON (Marquette)—Ten more retorts are to be added to the furnace plant. Ten are now being constructed.

CLEVELAND-CLIFFS IRON (Ishpeming)—At special meeting of shareholders, held Dec. 1, it was decided to increase capitalization of company from $5,000,000 to $10,000,000.

AMERICAN (Diorite)—Two electric pumps now taking water from big swamp that overlies part of orebody. Water level was lowered 20 ft. by sinking 6 large sandpipes and forcing water to surface by air.

MINNESOTA

Mesabi Range

BARNETT & RECORD (Two Harbors)—Has been awarded contract for dismantling No. 2 Dock of Iron Range R.R., which is to be superceded by $1,500,000 steel and concrete dock. Old No. 3 Dock will not be torn down until completion of the new dock.

ARTHUR MINING CO. (Hibbing)—Three large steam shovels have been ordered from the Bucyrus Co.; will weigh 315 tons each. Booms will be 75 ft. long; dipper capacity will be 7 yd. Will be possible to make cut 50 ft. deep with them. Three Osgood shovels have also been ordered. Eight new locomotives will be delivered before spring.

LEONARD NO. 2 (Chisholm)—Electric locomotives operating on stockpile are handling three cars each, all side-dump. Ordinarily but one car is used, but change is necessitated because of unusual length of the stockpile. Distance to be trammed is so great that hoisting would be delayed if but one car were used.

MONTANA

Beaverhead County

BANNACK GOLD (Bannack)—Reported that ore assaying 36.8 oz. in gold and 43.7 oz. in silver was encountered in No. 2 Thompson stope of Golden Leaf mine. It has been opened up at a point about 280 ft. from surface. Company has blocked out in neighborhood of 160,000 tons of milling ore. It has been decided to block out at least 200,000 tons before beginning construction of amalgamation and cyanide mill, which will probably be started Mar. 1.

Blaine County

LITTLE ROCKIES DISTRICT—Considerable mining excitement around Landusky, Whitcomb and Ruby Gulch; gold-bearing claims being worked on increasing scale. Mining at Zortman has been in progress for years. Eastern capitalists have taken options on claims, aggregating in value $150,000, and installation of big mining plant near Landusky may follow.

Deer Lodge County

WASHOE REDUCTION WORKS (Anaconda)—Construction work is making rapid strides. New roaster building is nearing completion and bricklayers are now busy on building and lining roasters. Large flue for roasters was started last week, also erection of 1,000-ton coal bin for pulverizing plant. Slime-flotation building is also nearing completion and concentrate tank-house is being retimbered.

Lewis & Clark County

SCRATCH GRAVEL MINING DISTRICT—Resumption of operations at Head properties in this district by John MacGinnis, H. L. Wilson and associates of Butte, and fact that they are taking good pay ore out of property, has started great amount of prospecting in adjoining claims and has created mild boom in district.

Silver Bow County

ANACONDA (Butte)—Work on old Alice mine at Walkerville, stopped for some time because of litigation, resumed.

EAST BUTTE (Butte)—Now producing at rate of 20,000,000 lb. of copper per annum at a cost of 10c. per lb. New flotation plant is practically ready for operation.

BUTTE-DULUTH (Butte)—Capt. A. B. Wolvin, who owns three-fifths of stock and some bonds of company, will soon announce arrangements made for taking care of most pressing claims and property, only one now idle in Butte, will be operated again.

DAVIS-DALY (Butte)—About 75 tons of ore per day being mined and shipped from Colorado mine, running about 7% in copper. It is probable that November profits will amount to $10,000. Planning to install new hoisting engine; also to cut out shoulder between 1,700 and 1,900 levels to make three-compartment shaft down to 2,500 level, which would enable company to increase output to 400 tons of ore per day.

NEVADA

Esmeralda County

JUMBO EXTENSION (Goldfield)—During quarter ended Sept. 30 shipped 8,354 dry tons, gross value $325,040, on which the smelting loss was $37,721, freight and treatment $73,274, sampling $5,406, and mine costs $47,348, leaving net realization of $161,289.

REORGANIZED KEWANAS (Goldfield)—On 840 level from main winze and about 300 ft. northerly from it, new winze has been started on vein near hanging wall to go to latite-shale contact and explore vein at that horizon.

GOLDFIELD CONSOLIDATED (Goldfield)—Production for October was 36,500 tons and net realization $98,375. Net operating costs were $4.40 per ton. Leasers produced 119 tons valued at $3,995. Ore transportation to mill over Consolidated line now being handled under contract by T. & G. railroad.

Nye County

TONOPAH ORE PRODUCTION for week ended Nov. 27 was 9,951 tons, estimated value $265,078, compared with 10,093 tons for week previous. Producers were: Tonopah Belmont, 3,006 tons; Tonopah Mining, 2,900; Tonopah Extension, 1,850; Jim Butler, 1,100; West End, 647; North, Star, 52; Halifax, 49; miscellaneous leases, 347 tons.

HALIFAX-TONOPAH (Tonopah)—On 1,200-ft. level at point of recent ore discovery, work of cutting station and installing hoist at collar at 40-ft. winze completed and sinking resumed. Progress at Halifax is being watched with interest as it holds large possibilities in eastern extension of Tonopah's proven ore zone.

TONOPAH BONANZA (Tonopah)—Greenwater Copper Mines and Smelting Co. through purchase of 200,000 shares of treasury stock and other large interests has acquired control of this property from Herman Zadig, of San Francisco. John Magee has been appointed superintendent. Although no details have been given out, it is stated that shaft, which has present depth of about 1,040 ft., will be equipped to sink to 2,000-ft. mark. This marks entrance of another strong company into development of Tonopah's western section.

Storey County

ANDES (Virginia)—Saved 10 cars ore from stope above 175-ft. level.

SIERRA NEVADA (Virginia)—From stope in 2,500 level shipped 91 tons to the mill; average assay $14.22 per ton; southeast drift from west crosscut in low-grade ore.

CROWN POINT-BELCHER (Gold Hill)—Extracted 251 cars of ore from No. 1 stope on 1,600 level and shipped 575 tons of dump rock and 225 tons of mine rock to the mill; bar of bullion shipped.

UNION & SIERRA NEVADA (Virginia)—Joint east crosscut from 100-ft. point in raise above 2,500 level shows face of $50 ore. Saved from this work 28 cars of ore averaging $65.48 per ton.

MEXICAN (Virginia)—East crosscut 2,700 level in porphyry and quartz of low assay. Mexican mill crushed 168 tons of custom ore, average assay $25.63 per ton. Mill idle 4 days on account of delayed shipment of zinc dust.

OPHIR (Virginia)—In southwest drift 2,500 level, at 271-ft. point 4 ft. of low-grade quartz exposed in upper blast; porphyry and quartz also at 126-ft. point. Central tunnel north drift in milling quartz over 2 sets wide. Saved from stopes 362 cars of ore and milled 331 tons.

UNION (Virginia)—From north end No. 3 stope 2,500 level saved 14 cars averaging $10 per ton; from south end saved 21 tons averaging $33.42 per ton. Saved from raise No. 1 14 tons, averaging $21. Top of raise in $19 ore. Sill floor northeast drift shows $10 ore in face.

UTAH

Beaver County

FORTUNA GOLD QUEEN (Beaver City)—Being prepared for more extensive development; lumber for four buildings has been received; expected to have these ready before cold weather sets in. Considerable opencut work is being done. Ore from Davis lease has been tried out at Sheep Rock mill, and good saving made. Ore has been opened on another lease, and work is being done to cut extension of vein productive in Davis lease.

Juab County

UNCLE SAM (Eureka)—Tunnel being driven to prospect for continuation of recent Yankee strike. Leasers are mining some ore in old workings.

RIDGE & VALLEY (Eureka)—Lead-silver ore of good grade has been opened from 1,600 to 1,670-ft. level, and is being mined. Workings are being put in shape for increased production.

Salt Lake County

SOUTH HECLA (Alta)—Face of 500 level, which is being driven on Wedge fissure, is heavily mineralized, and carries bunches of ore in places. About 6 ft. a day progress is being made.

MONTANA BINGHAM (Bingham)—Conger vein has been cut in this company's tunnel. Bingham Conger Copper Co. claims that vein apexes on its ground and is working 20 men with view to proving this.

OHIO COPPER (Bingham)—General Exploration Co. is mining and milling 2,000 tons of ore a day. Minimum royalties amount to $6,250 a month, according to the terms of the lease, and have averaged around $15,000. Royalties are 10% on 16c. copper, 14% on 18c. copper, 16% on 19c. copper, etc. Lessees are reported to be making upwards of $20,000 a month.

SELLS (Alta)—Ore shipments are to be started soon from this property adjoining South Hecla, as soon as hauling conditions permit, roads at present being congested with shipments from latter property. Orebins and ore chute from top of dump to bins are completed. Hauling is now done by sleds to Tanner's Flat and from there by wagon to Wasatch over a poor road.

Summit County

PARK CITY ORE PRODUCTION for November amounted to 5,855 tons, estimated at $234,200. This is compared with 8,262 tons shipped in October from four principal producers; five shipping weeks entered into October, while only four were counted in November. The strike, with a 10-day tie-up, at the Coalition, heaviest producer in camp, cut down aggregate one-third from normal output. Producers were: Daly-Judge, 2,010 tons; Silver King Coalition, 1,220; Silver King Consolidated, 1,100; Daly West, 890; Ontario, 75; Daly, 60; others, 500.

DALY-WEST (Park City)—Work is to be resumed at No. 3 shaft and this section of mine is to be unwatered to 1,700-ft. level.

SILVER KING CONSOLIDATED (Park City)—Galena ore has been opened near east end of 1,700 level. Water-tank holding 23,000 gal. has been built on hill slope 186 ft. above collar of shaft for fire protection.

Tooele County

LION HILL CONSOLIDATED (Ophir)—Shipments begun in spring from St. Clair lease are stated to have amounted to $50,000. Siliceous silver ore carrying some lead and gold has been followed for 300 ft.

WISCONSIN

Zinc-Lead District

STONER (Linden)—Stoner Bros. has completed a 50-ton mill at Linden.

VINEGAR HILL ZINC (Platteville)—Company is building 200-ton mill on Blackstone tract at New Diggings.

K. M. & C. (Platteville)—Ray Keating and others are building 75-ton mill on Wilkinson property at Benton, surface equipment of which was destroyed by fire early in summer.

WISCONSIN ZINC (Platteville)—Contemplates building four mills, 200 tons each, on Longhorn, Birkbeck, C. A. Thompson and East End Champion. New Skinner roaster at Champion mine has been put in operation; plant is equipped with six Cleveland-Knowles separators and will handle 800 tons of green ore per week.

CANADA

Yukon Territory

NORTH WEST CORPORATION (Dawson)—Considerable additional stripping work done during current season. Excavating and washing plant installed to treat the gravel of Dominion Creek. A. N. C. Treadgold, managing director. This company is subsidiary of Granville Mining Co. of London and New York.

MEXICO

Pachuca

SANTA GERTRUDIS (Pachuca)—Ore crushed during October, 20,503 tons; estimated profit, £6,740.

SOUTH AMERICA

Chile

BRADEN COPPER (Rancagua)—During September mill treated 89,361 tons of 2.02% ore; produced 7,908 tons of 13.12% concentrates. Minerals Separation treated 87,110 tons; concentrates, 20.77%; copper produced, 1,611 tons.

ASIA

Chosen

ORIENTAL CONSOLIDATED (Unsan District)—Tonnage milled during October was 25,432 and bullion shipments amounted to $135,537. Cable advices are that November cleanup amounted to $144,800. Value of the ore milled was above average.

The Market Report

Metal Markets

NEW YORK—Dec. 8, 1915

All of the principal markets were softer last week, but the recession in prices was trifling in all cases with the exception of spelter, which became rather demoralized.

Copper, Tin, Lead and Zinc

Copper—Business was light, but there were moderate transactions from day to day both with domestic and foreign buyers. The producers generally asked 19¾c., r. t., and some of them reported business at that figure, while others reported that they had been unable to get it. From certain first hands copper was available at 19⅝c., r. t., and a round lot was reported sold at that price on Dec. 3. Sales for delivery in Europe were made at £97 on Dec. 2, and at £98@98½ on the following days. Computations of the New York cash equivalent of these prices were variable owing to the uncertainties of freight rates and exchange. During the last week contracts for carrying copper to Europe were made on the basis of $1 per 100 lb., which a few months ago would have been an incredible figure. Some sales of copper for export were made during the last week on the basis of f.o.b., New York, some of this business being done at 19¼@19½c. Copper prices during the week exhibited a considerable range, there being variations among sellers and also according to deliveries, prices being a little stiffer for near-by deliveries than for the later ones.

Copper Sheets, base price is 25c. per lb. for hot rolled and 26c. for cold rolled, with usual extras. Copper wire is 21@21½c. per lb., carload lots at mill.

Copper Exports from the United States for the week ended Nov. 20 are reported by the Department of Commerce at 19,551,362 lb. The principal items were 7,318,441 lb. to France, 5,977,122 lb. to Italy and 4,009,809 lb. of England. Copper imports for the week were: Metal, 6,348,058 lb.; in ore and matte, 518,133 lb.; total, 6,866,191 lb. The larger imports were from England, Peru, Canada and Chile.

Visible Stocks of Copper in Europe on Nov. 30 were: Great Britain, 13,572; France, 1,473; afloat from Chile, 2,400; afloat from Australia, 3,500; total, 20,945 long tons or 4,691,680 lb. This is a decrease of 623 tons from Nov. 15; and of 3,980 tons from the Oct. 31 report.

Tin—But very little business was done. Owing to the small demand and the larger arrivals the market declined.

Visible Stocks of Tin on Nov. 30 were: United States excluding Pacific ports, 10,062; London, 5,514; Holland, 875; total, 16,451 long tons, or 3,685,024 lb. This is an increase of 3,297 tons during November.

Lead—Early in the week premiums continued to be realized for special brands of lead, but later the market became easier and the metal was available in nearly all quarters at 5.25c., New York, at which price there were more sellers than buyers.

Spelter—On relatively small business the market experienced a severe decline, for which there was apparently no special reason other than the perception of the hollowness of the recent advance. The foreign demand which previously had been the backbone of the market having ceased, temporarily at least, the producers beat a retreat. In the latter part of the week prompt spelter was available from many quarters at 15c., January, at 14c., January-February-March, at 13c. The bulk of the business that was done by producers was for January-March delivery. Spelter for delivery in the second quarter of 1916 was offered at much lower figures, there being apparently a willingness of some sellers to contract at less than 11c. for such business.

Arrivals at Baltimore for the week included 7,471 tons zinc concentrates from Port Pirie, Australia.

Zinc Sheets are in good demand but have not advanced this week, and the base price today is $22 per 100 lb., f.o.b. Peru, Ill., less 8% discount

Exports and Imports of the principal metals, other than iron and steel, in the United States nine months ended Sept. 30, copper and tin in long tons, lead and zinc in short tons:

	Exports		Imports	
	1914	1915	1914	1915
Copper	298,505	221,305	116,941	105,121
Tin	543	515	34,055	39,540
Lead	50,211	92,240	17,556	40,561
Zinc	24,946	95,922	819	715
Ores:				
Zinc	8,499	713	14,931	93,291
Zinc ore, contents	140	609	5,664	36,222

Exports include reëxports of foreign material. Copper includes contents of ore and matte; lead, contents of ore and base bullion.

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St Louis is given as the basing point. St. Louis and New York are normally quoted 0.17c. apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash The difference between the price delivered and the New York cash equivalent is at present about 0 20c. on domestic business. The price of electrolytic cathodes is 0 05 to 0 10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands Quotations for spelter are for ordinary Prime Western brands. Only the St Louis price is herein quoted, St Louis being the basing market We quote the New York price at 17c per 100 lb. above the St Louis price

Silver quotations are in cents per troy ounce of fine silver.

Some current freight rates on metals per 100 lb are: St. Louis-New York 17c.; St Louis-Chicago, 6.3c ; St Louis-Pittsburgh, 13.1c.

LONDON

		Copper				Tin		Lead		Zinc	
		Standard		Electrolytic							
Dec	Silver	Spot	3 Mos.	£ per Ton	Cts. per Lb.	Spot	3 Mos	£ per Ton	Cts. per Lb	£ per Ton	Cts per Lb
2	26⅛	79½	80	99	20.81	165¼	164½	28⅜	6 04	100	21 03
3	26 7/16	78¼	78¾	98½	20 71	168	167½	28¼	5 94	93	19.55
4	26 7/16	...	...	...							
6	27⅛	78	78½	98	20 50	166	165¼	28¼	5.94	89	18.71
7	26 9/16	77¼	77½	98	20 55	165½	165	27¾	5 87	87	18 33
8	26½	76½	77	98	20.55	166	165½	28¼	5.93	84	17.52

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 3 per cent discount For convenience in comparison of London prices, in pounds sterling per 2240 lb , with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4 80 : £ 15 = 3.21c ; £20 = 4 29c.; £30 = 6 43c.; £40 = 8.57c.; £60 = 12 85c Variations, £1 = 0 21¾c.

Exports of **Metals and Minerals from Spain** eight months ended Aug. 31, as reported by "Revista Minera" in metric tons:

	Metals		Ores, etc.	
	1914	1915	1914	1915
Iron	12,441	95,176	4,881,927	2,931,030
Copper	15,729	11,706	74,975	26,304
Copper precipitate	7,282	8,010	..	..
Lead	110,665	95,899	1,560	641
Zinc	1,454	2,843	65,306	21,579
Quicksilver	1,275	703	..	..
Manganese	..	..	7,238	5,439
Pyrites	..	..	2,079,658	1,299,281
Salt	..	..	417,075	352,864

Imports of coal for the eight months were 1,446,319 tons, a decrease of 309,734 tons from 1914; imports of coke, 128,027 tons, a decrease of 140,188 tons.

Other Metals

Aluminum—The market remains about the same. Imported metal is scarcer, and the American producer has none to spare for early delivery except on contract. Quotations are 57@60c. per lb. for No. 1 ingots, New York, for a spot delivery.

Antimony—The market continues strong, although business has been on a moderate scale. Supplies are low and prices are very firm. Chinese and other ordinary brands are quoted at 39@40c. per lb. Cookson's is held as high as 55c., with very little to be had. Under present conditions it costs close to 40c., duty paid, to import Chinese. Antimony ore is also in small supply and has been sold at $2.55 per unit.

Nickel—There is no change to be reported. Ordinary forms are 45@50c. per lb., according to size and terms of order. Electrolytic is 3c. per lb. higher.

Quicksilver—This metal has advanced sharply and is very firmly held. Stocks are very low. The New York quotations are $120@125 per flask of 75 lb. Some dealers will not quote, having no stocks or only enough to supply regular customers. San Francisco reports by telegraph a firm market, very light stocks and sales as high as $115 per flask, with little or no prospect of a decline. On the other hand, London price is unchanged at £16 10s. per flask, with the same quotation from second hands.

Minor Metals—Current quotations for **Bismuth** are $3 per lb., New York.—**Cadmium** is quoted as 7s. per lb. in London; $1.75@1.90 per lb., New York.—**Chromium metal,** 75c. per lb., New York.—**Cobalt metal,** 97% pure, is sold at $1.75@2 per lb.—**Magnesium,** pure, has gone to a high price, $6 per lb. being asked.—**Selenium** varies from $2.50@3 per lb., New York, for large lots; $4.50@5 for retail quantities.

Gold, Silver and Platinum

NEW YORK—Dec. 8

Gold in the United States Dec. 1 is estimated by the Treasury Department as follows: Held in Treasury against gold certificates outstanding, $1,427,167,399; in Treasury current balances, $221,663,793; in banks and circulation, $611,856,355; total, $2,260,687,547. This is an increase of $62,573,785 in November.

Gold sales from the United States Assay Office in New York in November were $3,679,450, being $226,686 more than in October, and $570,607 more than in November, 1914. For the 11 months ended Nov. 30, the total sales were $58,860,366 in 1914, and $31,572,157 in 1915; a decrease of $27,288,209 this year.

Platinum—There is no change in the market. Supplies are very scarce and dealers hesitate to make quotations, transactions being rather a question of negotiations. Quotations are approximately $70@74 per oz. for refined platinum and $71@78 per oz. for hard metal.

Iridium—This metal is also very scarce. No definite quotations can be given, sales being a matter of negotiation in each case.

Palladium—Some sales are reported at $45@50 per oz., according to size and terms of order.

Coined Silver in the United States Dec. 1 is estimated by the Treasury Department as follows: Standard dollars, $568,271,655; subsidiary coins, $188,695,357; total, $756,967,012. Of the standard dollars $489,093,355 are held in the Treasury against silver certificates outstanding.

Silver has had some reaction owing to the filling of the India orders in connection with Mint buying. The disposition of the English Mint is not to force the price up but to absorb the floating amounts of bullion at current rates

Exports of silver from London to the East Jan. 1 to Nov. 24, as reported by Messrs. Pixley & Abell:

	1914	1915	Changes
India	£4,679,500	£3,495,000	D. £1,184,500
China	42,000	7,000	D. 35,000
Total	£4,721,500	£3,502,000	D. £1,219,500

Stocks in Bombay are reported on Nov. 24 as reduced to 5,700 bars

Zinc and Lead Ore Markets

PLATTEVILLE, WIS.—Dec. 4

The base price paid this week for 60% zinc ore was $100 down to $94 at week end. The base price paid for 80% lead ore was $70 per ton.

SHIPMENTS WEEK ENDED DEC. 4

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	5,104,090	125,500	791,400
Year	195,231,750	5,643,500	27,325,710

Shipped during week to separating plants, 5,588,000 lb. zinc ore

JOPLIN, MO.—Dec. 4

Blende, high price, $107.35; base per ton 60% zinc, premium ore, $105; medium, $100@90; lower grades down to $85; calamine base per ton 40% zinc, $70@60; average selling price, all grades of zinc, $97.93 per ton. Lead, high price $72.90, base per ton 80% metal content, $70@71; average selling price, all grades of lead, $66.64 per ton.

SHIPMENTS WEEK ENDED DEC. 4

	Blende	Calamine	Lead	Values
Totals this week	11,825,620	1,063,950	2,236,520	$705,690
Totals this year	546,877,620	42,773,650	$5,146,700	25,202,770

Blende value, the week, $594,890; 49 weeks, $21,822,500.

Calamine value, the week, $36,280; 49 weeks, $1,098,150.

Lead value, the week, $74,520; 49 weeks, $2,282,120.

While this week's shipment is above an average one it is a drop of 2,700 tons from last week and shows the effect of the lower spelter market. During November the demand was exceptionally strong and practically all the reserve stock was shipped away, leaving only 1,700 tons at Granby where there was 4,000 tons a month ago. Miami is about cleaned up and none of the other camps have had more reserve than a two days' production at the end of the week for many months. Miners working on a sliding scale wage base will be paid during December on an average base price of zinc for November of $101.25, against $82 base of November wage scale. They were notified of this last Monday and nothing more was heard of the threatened strike.

Iron Trade Review

NEW YORK—Dec. 8

The iron and steel trades continue strong and active. The most notable change apparent is an increase in domestic orders and some falling off in steel for shells and other war munitions for export. The gain in domestic orders is largely in structural steel.

The control of the Cambria and the Pennsylvania steel companies seems to be still in doubt. Numerous rumors as to the condition of affairs and the projected combinations are current, but there is no certain information to be had.

The syndicate which is planning a combination of Eastern blast furnaces now has options on the Thomas, the Wharton, the Empire and the Crane iron companies. These companies together own 15 blast furnaces in Pennsylvania and New Jersey with iron-ore mines, coal mines and coke ovens. All are producing properties and would constitute an important block of merchant furnaces.

Exports from Baltimore for the week included 2,751,992 lb. steel bars, wire rods and skelp to Liverpool.

The Bethlehem Steel Co. is having plans prepared for the erection of three new blast furnaces at South Bethlehem. The Midvale Steel and Ordnance Co. is arranging to build an additional blast furnace at Coatesville, Penn., at the Worth Brothers plant.

PITTSBURGH—Dec. 7

The runaway market in steel products that was so apparent last month is being checked to an extent by the fact that there is little to run away. The steel mills are filled up solidly with business for months to come, while buyers with scarcely an exception have gotten their tonnages onto the mill books, the real question in the trade being one of arranging deliveries so as to discommode the smallest number of buyers, of course paying attention to the sequence in which specifications have been received. This sequence is not the governing element in all instances by any means as cases are cited of buyers desiring some of their later specifications to be filled before earlier specifications.

Finished-steel prices have become practically nominal in the majority of lines. While precise quotations are available as representing the market in general it is frequently impossible to buy at them. Thus bars, plates and shapes are 1.70c., with premiums for early delivery, and open contracts usually refused at any price. Sheets are strong at 2.50c. for black, while 2.25c. on blue annealed has become practically nominal. The leading interest quotes nominally 4.75c. on galvanized, but is practically filled up for three months. Wire mills are congested with business.

A situation has been reached in which the purely domestic demand for steel is beyond any previous record and the war demand, while important, is no longer the principal element in the market. Recent rumors that the Allies will buy less when present contracts for war steel expire do not seem to cause the least concern in the steel industry

Pig Iron—The boom in steel has reached pig iron, as prices are advancing sharply with a comparatively small turnover, all indications being that the trade is facing an actual scarcity. The supply of idle furnaces to come in and retard the advance seems now to be exhausted. Sales of bessemer pig iron reported in the local market include 3,500 tons at $18, an advance from $17.50, 1,100 tons at $18.50 and 1,000 tons, in two lots of 500 tons each, made this week at $19, apparently the minimum of the market today and representing an advance of $1.50 on a turnover of scarcely more than 5,000 tons, altogether an unprecedented performance for bessemer iron. It is stated that a firm bid of $20 for January delivery has been turned down. Foundry iron is in fairly large request and prices have been advancing sharply, by 50c. to $1 in the week. Basic shows no activity and the last important domestic sales, at $16, Valley, have no bearing on the present situation. There have been sales for export at around $18, Valley, but under peculiar conditions. We quote: Bessemer, $19@20; basic, $17@18; foundry and malleable, $17.50@18; gray forge, $17@17.50, f.o.b. Valley furnaces, 95c. higher delivered Pittsburgh. W. P. Snyder & Co. report average prices in November, computed from actual sales in 1,000-ton lots and over, at $16.615 for bessemer, an increase of 61.5c., and $15.518 for basic, an increase of 50.33 cents.

Ferromanganese—Better deliveries of English ferromanganese are in sight and the $100 contract price is a definite factor, domestic producers being therefore disposed to recede from their former quotation of $110. Prompt lots bring about $100 per ton.

Steel—Hardly anything is being done in the open market, steel being so scarce. A producer of openhearth steel has bought a round lot of bessemer billets at $29 for use in its finishing mills, giving it more openhearth steel to sell in unfinished form. Several similar transactions, by other mills, were reported last month. The market is quotable at $29 for bessemer billets and sheet bars and $30 for openhearth, at maker's mill, Pittsburgh or Youngstown, but the quotations are practically nominal. Forging billets are $48@50 and rods $38@40, Pittsburgh.

Foreign Trade in Iron and Steel in the United States 10 months ended Oct. 31 is valued by the Department of Commerce as below, the figures including machinery:

	1914	1915	Changes
Exports	$152,776,839	$251,112,482	I. $98,335,643
Imports	22,905,321	14,818,206	D. 8,087,115
Excess, exports	$129,871,518	$236,294,276	I. $106,422,758

The chief changes were in the later months. September exports were more than three times those of last year.

FERROALLOYS

Ferrosilicon, high grade, 50%, is $83@85 per ton at furnace, according to size of order; bessemer ferrosilicon, from $84 at furnace for 16%, down to $24 for 10%, for 1916 delivery. Spot is $1 higher.—**Ferrotitanium** is 8@12.5c. per lb., according to size of order.—**Ferrovanadium** $2.25@2.50 per lb. of contained vanadium.—**Spiegeleisen,** $28@30 per ton at furnace.—**Ferrotungsten** is very high and irregular. Sales have been reported as high as $6 per lb. of contained tungsten; while **Tungsten** metal has sold at $7 per lb. for 98% pure metal.

IRON ORE (By Telegraph)

Pittsburgh, Dec. 8—Lake Superior iron-ore prices for next season are announced today as follows: Old Range bessemer, $4.45; Mesabi bessemer, $4.20; Old Range nonbessemer, $3.70; Mesabi nonbessemer, $3.55; all f.o.b. Lake Erie ports. The advance over last season's schedule is approximately 75c., except that Old Range bessemer advances only 70c. Some of the producers favored an increase of $1. The new prices are 50c. below the schedules obtaining in 1907 and 1910, which were the highest since the 1900 season.

OTHER ORES

Tungsten Ore—The Primos Mining and Milling Co., one of the large purchasers of tungsten ores, has recently published a revised schedule of purchase prices for Colorado ores. Under prevailing market conditions, miners are doing remarkably well mining ore of as low grade as 2% which sells for $29 per ton or at the rate of $14.50 per unit, a figure double that paid 18 months ago for 60% material which is now worth $35 per unit or $2,100 per ton. Intermediate figures in value per ton are as follows: 3%, $46; 4%, $92; 5%, $115; 10%, $230; 15%, $345; 20%, $460 per ton.

COKE

Connellsville—The market for furnace coke is quiet, but there is an undertone of strength, there being few sellers at quoted prices of $2.15@2.25 for prompt furnace, and a definite scarcity may develop over the holidays, as is usually the case. There is no demand for contract furnace coke, quotable nominally at $2.35@2.50 for first half and $2.25@2.35 for the whole year. Foundry coke is firm and moderately active at $3@3.25 for prompt or contract, per net ton at ovens. The sharp advances occurring in pig iron are not necessarily favorable to the coke market, as they indicate a scarcity of pig iron due to there being few if any idle furnaces to be blown in, so that no increased consumption of coke is suggested by the pig-iron advance.

Coal and Coke Shipments, Pennsylvania R.R. lines east of Pittsburgh and Erie, 10 months ended Oct. 31, in short tons:

	1914	1915	Changes
Anthracite	9,067,445	8,687,790	D. 379,655
Bituminous	37,840,834	35,983,366	D. 1,857,468
Coke	8,277,868	9,604,424	I. 1,326,556
Totals	55,186,147	54,275,580	D. 910,567

October total tonnage was 6,615,053 tons, an increase of 875,511 tons over last year.

British Fuel Exports, 10 months ended Oct. 31, in long tons:

	1914	1915	Changes
Coal	52,060,846	36,944,758	D. 15,116,088
Coke	975,254	798,188	D. 177,066
Briquettes	1,487,943	1,087,660	D. 400,283
Steamer coal	16,037,409	11,745,472	D. 4,291,937
Total	70,561,452	50,576,078	D. 19,985,374

The steamer coal is fuel furnished to steamships in foreign trade. Imports are very small.

Chemicals

NEW YORK—Dec. 8

The general market seems to have a stronger undertone and business looks better for next year.

Arsenic—The market is still rather quiet with small sales. Quotations are $3.75@4 per 100 lb; but it is claimed that they can be shaded for a good order.

Copper Sulphate—Business has been chiefly in small lots. Prices have advanced sharply, the current quotations being $10 per 100 lb. for carload lots and $10.25 per 100 lb. for smaller orders.

Nitrate of Soda—The position is very strong, notwithstanding the increased production in Chile. This has been offset by the difficulty in getting ships, and the high ocean freights. The quotations are firmer, spot being especially strong. As high as $3.25 per 100 lb. is asked for spot, while $3 per 100 lb. is named for futures.

Shipments from Chile for the 10 months ended Oct. 31 are reported as below, in tons:

	1914	1915	Changes
United States	454,950	713,700	I. 258,750
Europe	1,072,400	775,300	D. 297,100
Totals	1,527,350	1,489,000	D. 38,350

Pyrites—Arrivals at Baltimore for the week included 2,514 tons of pyrites from Spain.

Imports and Exports of Chemicals in the United States nine months ended Sept. 30, in pounds:

	Imports		Exports	
	1914	1915	1914	1915
Arsenic	3,171,867	2,655,334	700	8,825
Bleach	29,185,862	6,779,926	12,654	120,126
Acetate of lime			41,514,968	17,586,573
Calcium carbide			20,401,723	28,869,280
Potash salts	25,065,751	13,960,537	481,655	983,178
Sodium cyanide	1,240,904	3,662,888		1,796,927
Soda salts, value	$468,664	$361,313	$10,061	$22,635

Exports include reëxports of foreign material. This statement does not include nitrate of soda nor crude potash salts used chiefly as fertilizers.

VOLUME 100 DECEMBER 18, 1915 NUMBER 25

Sluicing Methods at Fairbanks

By Hubert I. Ellis*

SYNOPSIS—Gravel is sluiced as fast as mined in summer. Construction of sluice and dump boxes varies with conditions, although the principles hold throughout. Pole riffles are usually employed, although occasionally the iron-bound Hungarian type is in service. Methods of cleaning-up are described.

Except for small-scale operations at the heads of the creeks and at other places where water is scarce during dry weather, gravel mined during summer at Fairbanks, Alaska, is sluiced as fast as hoisted. The bucket is dumped on an inclined platform, or apron, which discharges into the mud box, or dump box. Here the lumps of sticky clay are broken up and the large rocks removed. Following the dump box, which is larger and of more substantial construction than the sluice boxes, comes the main sluice, consisting of five or more 12-ft. riffled boxes and additional false-bottom boxes to distribute the tailings. Dump box and sluice are placed on light timber trestles at sufficient elevation to give plenty of grade to the boxes and to provide room for the disposal of tailings.

*Kellogg, Idaho.

Fig. 1 shows the relation of the apron to the dump box and also the construction of a typical dump box. The box is usually equipped with block riffles and is given a grade of 3 to 12 in. in 12 ft., 10½ in. being a common figure. This grade is about the same as that of the sluice boxes and is often insufficient for the dump box in which the current, owing to the greater width of the sheet of water and the constant interference from dumping and forking, is considerably less. To obviate this difficulty the intake from the flume is commonly placed at a relatively higher position in the box than the outlet.

The apron, which may or may not be covered with sheet iron, is made of light poles or plank. When poles are used without an iron cover, considerable fine dirt sifts through and gold is thus lost.

MAKING A CLEANUP AFTER SLUICING PART OF THE WINTER DUMP

Sluice boxes are made in sizes ranging from 10 in. wide at the small end to 14 in., the 12-in. size probably being most used. Details of construction of such a box are shown in Fig. 2. The ordinary telescope box, owing to ease of setting and changing, is most widely used, but some operators prefer the box illustrated in Fig. 3, which is built after the order of the ordinary flume box, on the ground that it does not clog so easily. This seems largely a matter only of individual taste.

The flimsy construction of these boxes is a marvel to one accustomed to the heavy material used for the sluices in large hydraulic mines. One-inch lumber, planed on one side so that its effective thickness is not more than ⅞ in., with 2x4-in. braces, makes a box that can be handled with ease and that will take care of all the gravel that can be passed through it in one season—usually less than 15,000 cu.yd. Next year is another matter in the view of the average operator, for he may have made his stake, he may have failed so heavily as to lose his plant, he may have sold out or he may have moved to another creek or even to another district. In any event the boxes are sure to require resetting, and the expense of constructing four or five new ones to save the bulk of the gold is comparatively slight. (The materials for a box cost about $2.50.) The native timber of the Tanana makes a poor grade of lumber, and sluice boxes, while idle, will warp and crack in such manner as greatly to decrease their effectiveness. Consequently it is considered good practice to equip only the best of these old boxes with riffles, using the others as false-bottom boxes for distributing the tailings. These false bottoms are also of one-inch material and serve to protect the bottoms from

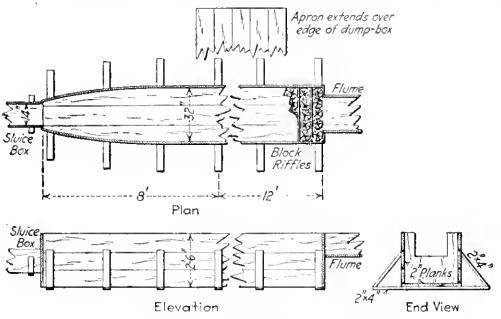

FIG. 1. DETAIL OF DUMP- OR MUD-BOX

excessive wear, especially at the drop where a box receives the discharge from the one above.

Sluice boxes, when used for any length of time, accumulate important quantities of gold in cracks, joints, splinters and abraded portions and knot-holes. To recover this they are burned after being discarded. Some have yielded more than an ounce of gold dust. Before laying aside for the winter, if it is thought that they carry considerable gold, they are frequently dried thoroughly over the boiler and pounded on canvas to recover as much as possible without destroying their utility.

Grades and Riffles Depend on Various Factors

The grade at which the boxes must be set depends on the amount of water available, the coarseness and quantity of the gravel, the type of box and riffle, and on the fall that can be used and still leave room for disposal of tailings. With pole riffles and telescope boxes the average is about 10 or 10½ in. per box-length of 12 ft.—although in reality it is more than this, since the effective length of box, owing to overlapping, is less than 12 ft. Theoretically, the thinnest layer of water that will carry away the material is best for saving gold, and a wide sluice with comparatively low velocity is advisable. In practice it is found that a comparatively high grade is necessary to save fine gold and that less water is then required, which is an important point in many parts of the Fairbanks district. For these reasons narrow boxes with steep grades are employed.

Many kinds of riffles have been tried at Dawson and Nome, but the Fairbanks operators have been too well satisfied with the ordinary pole riffle to seek earnestly for a substitute. These (see Fig. 4) are made of peeled spruce poles 2 or 3 in. in diameter, in 6-ft. lengths or slightly less, with head pieces of proper length to fit tightly into the boxes. They are held in place by nails driven into the head blocks through the sides of the boxes; the nails are allowed to protrude enough so that they can easily be withdrawn with a clawhammer when it is wished to remove the riffles. The poles wear out quickly, which might be prevented by protecting them with iron strips, but they are so inexpensive and quickly made that this is not considered necessary.

An iron-shod cross-riffle, known locally as the Hungarian, is very efficient as a gold saver, and it is not unusual to equip one or two boxes with it, the others

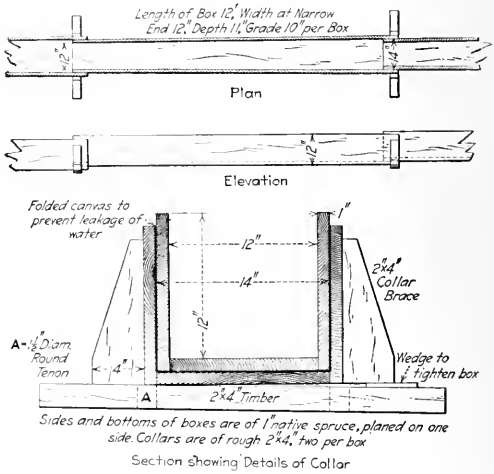

FIG. 2. TELESCOPE TYPE OF SLUICE BOX

having pole riffles. Some operators prefer the Hungarian for all boxes, but it is more expensive and has the disadvantage of clogging more easily than the pole riffle.

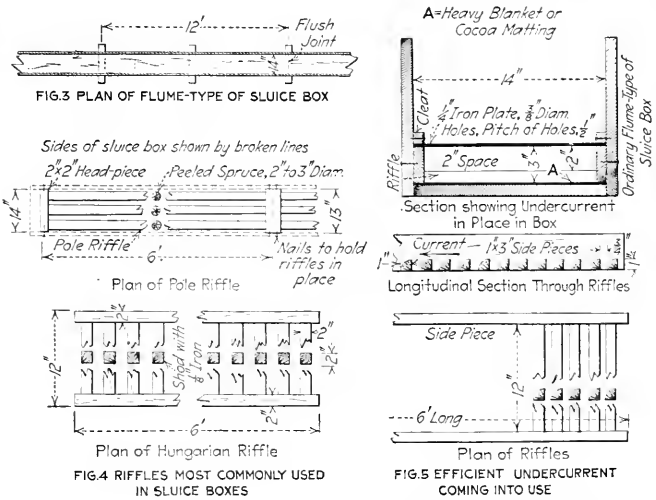
Refinements in the matter of gold-saving devices have attracted little attention at Fairbanks. Transverse undercurrents of the usual type, in connection with punched-iron screens, coco matting and amalgamated plates, have been tried with moderate success, but they have not in many cases returned the cost of installing, which may be partly owing to lack of intelligent attention. One serious objection to their use is that they remove large quantities of water from the sluice, causing the coarse tailings to pile up at the end of the boxes.

A new type of undercurrent designed to overcome this difficulty is shown in Fig. 5. It was tried out with excellent results during the summer of 1914 by E. M. Keys, of Chatanika. In four months gold to the value of $2,600 was saved, as against a few hundred for all season using the old-style undercurrent. It is essential, however, that

boxes equipped with it be cleaned up every two days, since its efficiency decreases greatly thereafter. Two boxes of the flush-joint type shown in Fig. 3 are fitted with this riffle, and one is cleaned up each day. In doing this it is a simple matter to remove the plate and riffles and rinse off the blanket and coco matting in a tub of water. This is done, of course, at a time which will not interfere with sluicing operations. The same riffle, installed on claim No. 7 Below Discovery, Cleary Creek, where, owing partly to the fine character of the gold previous attempts at mining had resulted in failure, recovered 20% of the entire cleanup. This gold, which had been lost before, made it possible to operate at a profit.

It has generally been held by Fairbanks operators, in view of the failure of the ordinary type of undercurrent and amalgamated plates materially to increase the saving, that very little fine gold occurs in the deposits of the district. The experience of Mr. Keys proves the falsity of this contention and indicates that there is much room for improvement in methods of gold recovery.

A string of boxes is rarely called on to handle more than 150 cu.yd. of material in 10 hr. and it handles this easily if a reasonable amount of water is available. The gravel dumped on the apron rolls or slides into the dump box, where the dump-box man stands in hip boots, armed with a broad sluice fork of eight or more strong tines. The fresh gravel is worked over by means of the fork until it gradually washes away, the large rocks being thrown over the side of the box. It was formerly considered the best practice to have the shovelers throw all large rocks behind them underground, but it is becoming customary to send all these that are not too large to the dump box, since this allows them to be washed clean and avoids delay on the part of the shovelers. At some mines the rock piles become so large that it is necessary to place a car and track at the elevation of the dump box to wheel the rocks away. Considerable skill and conscientiousness are required on the part of the dump-box man (who must work during summer with his feet in ice-cold water and his head in the blazing sun) especially when water gets low and gravel comes faster than usual, for there is often a tendency to use the fork as a shovel and remove much fine material with the coarse rocks, thus losing considerable gold. The dump-box man also, if he has time, takes care of the sluice boxes and the tailings discharge, swinging the tail boxes from side to side and adding new ones as they are needed.



FIGS. 3 TO 5. RIFFLE TYPES AND UNDERCURRENT ARRANGEMENT

The Problem of Water and Means of Handling It

The semi-aridity of the climate of the Yukon basin and the low gradient of the streams combine to make the water question a serious one. Gravity water for sluicing is obtained at Fairbanks wherever it is possible to do so without prohibitive expense, but the comparatively small scale of the operations, coupled with the large number of individual operators and their proneness to move from claim to claim and from creek to creek, has prevented the development of an efficient ditch system. The only ditch of any importance is the Cleveland, which takes water from the Chatanika River and delivers it to the mines at the mouth of Cleary Creek at such elevation that pumping is not required. The price charged is about $1 per sluice-head per hour. There are many smaller ditches that lead the water from each creek up on the benches, where it may or may not require pumping, but these do not go beyond the watershed of the individual creeks to obtain their supply. The amount of water required varies with size of boxes, grade, character and quantity of gravel, etc. The amount that will keep a given set of boxes running freely under whatever conditions they happen to be working is termed a "sluice-head," irrespective of the actual second-feet flowing.

Where water cannot be obtained by gravity, resort must be had to pumping, and where it is very scarce it must be impounded and used over and over, the portion that escapes by seepage and otherwise serving to replenish the supply of the next lower operator. In returning the water the boxes are usually so arranged as to discharge upstream and ponds are made by fencing with low dams made of brush or moss weighted with gravel, mud or sand; they are characterized by a considerable horizontal area and small depth.

On account of the dirt and grit in the water centrifugal pumps are used exclusively for raising it to the boxes. These are usually of the Worthington or Snow makes, 6- to 8-in. discharge pipe, driven by belt from 20- or 25-hp. horizontal engines. The lift varies from 20 to 35 ft. With wood costing $12 or more a cord the cost of pumping assumes formidable proportions, and this is one place where cheaper power will be of inestimable benefit. An effort will be made to introduce oil engines for pumping, and it is probable that this will result in an important saving to the district.

Method of Cleaning Up the Boxes

The cleanup, which is usually made weekly or at 10-day intervals, is simple, although details vary more or less at different mines. The riffles are first removed by withdraw-

ing the nails holding them to the boxes and are washed free from all adhering gold and gravel. As a general thing, except perhaps once a month or at the end of the season's work, only the upper boxes are cleaned up, since these and the dump box catch by far the greater proportion of the gold. If it is not desired to take the time and labor necessary for a careful cleanup, the gold may be concentrated without moving, but it is more often shoveled into pails or pans and carried to the upper boxes. A box that is smooth and comparatively free from knotholes, cracks and seams, near the lower end of those to be cleaned, is then chosen, and a block of wood 2 or 3 in. high is fitted tightly into this to serve as a dam to catch the black sand and other concentrates.

Water is next turned on in just sufficient quantity to move the material slowly down the boxes and is carefully regulated to prevent too rapid movement, since the gravel and gold, on passing from a rough box into one with a smooth bottom, are likely to be flushed down too quickly, in which case they may over-ride the dam and make it necessary to carry everything back to the upper boxes. Two or three men, with wooden paddles about 3 ft. long and 3 in. wide, work over the concentrates as they wash down, placing the paddles on the bottom and pushing up against the current through the concentrates. Care is taken to keep far enough down, moving from place to place, to avoid disturbing the gold, which collects at the upper end and becomes cleaner and cleaner as the whole gradually works down the boxes. All rocks of any size are thrown out by hand. The water is turned off while the gold, containing considerable black sand and other impurities, is several feet above the wooden block inserted as a dam. A large flat rock is placed against one side of the box, and the enriched concentrate is brushed over against this side. A little water is then turned on, and the gold is cleaned by brushing the water against the concentrate with a stiff whisk-broom, something after the order of the *planilla*. The black sand is gradually washed away, the gold remaining behind in a comparatively clean condition. (See Fig. 6.) The cleanup may be expedited by dividing the concentrates into two or more parts to be worked over by two or more men. In any event one man usually goes over the upper boxes with a whisk broom and carefully brushes down all gold that has remained behind. This is not done if only a rough cleanup is desired, and if little time is available the concentrates as stopped by the dam, gold and all, may be removed at once from the box and cleaned by panning or otherwise.

In cleaning the gold in the boxes, some of it escapes and washes down with the back sand to the dam. Some of this is fairly coarse, but much of it is fine and flaky and can be removed from the black sand only with considerable difficulty. The blank sand is shoveled out and stored in barrels or boxes, or it may be put back into the sluice. It is sold to professional black-sand cleaners or is cleaned by the operator himself at the end of the season. It is sometimes treated with a dilute solution of potassium cyanide to clean any rusty gold that may be present and then ground in a home-made cleanup barrel with mercury. The amalgam is recovered by means of a funnel and bowl, as shown in Fig. 7.

The impure gold dust removed from the boxes is freed of iron and magnetite by means of a small horseshoe magnet. It is then usually screened into two or more sizes. The coarse pieces are picked over by hand and all foreign material is discarded, while the fine part is cleaned by blowing in the well-known rectangular trays. This operation, though apparently simple, is one requiring skill and experience. The dust is flipped into the air by a peculiar underhand rotary-jerking motion, the heavy gold being thrown back toward the operator while the lighter impurities and some gold work out toward the front of the scoop. The operator blows lightly with his breath to assist in the separation, and in this manner all light impurities are gradually removed. It is a tedious operation and one requiring great pains, so it is not surprising that many miners send their dust to the bank in a very impure condition. One operator, when chided for this by the assayer, pointed to a huge tailing pile, saying that in removing all that from the gold he thought he had done his share. Impure gold may be cleaned by the bank assayer in the presence of the depositor, in which case the "blowings" are returned, or the impurities may be fluxed off in melting into bars for shipment.

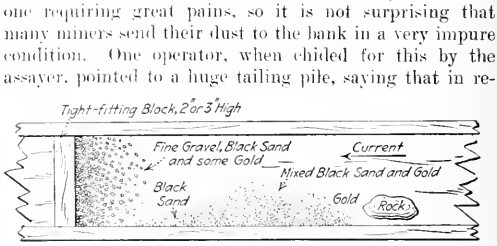


FIG 6 REMOVING BLACK SAND FROM CLEANUP

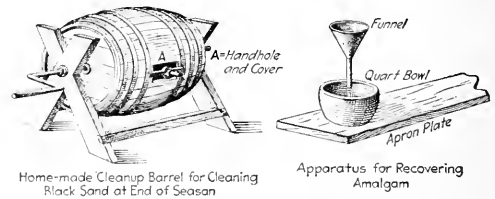

FIG 7 APPARATUS FOR CLEANING BLACK SAND

FIGS. 6 AND 7. METHOD AND APPARATUS FOR CLEANING UP

Briefly, the operator sells his gold dust to one of the two banks at Fairbanks, receiving a cash advance within safe limits if it is desired, and final payment on completion of the assay. The bank charges for handling are 2½% of the value of the gold; that is, the depositor receives 97½% of the value his gold will have when made up into coin by the Government, all charges being paid by the bank out of its 2½%.

Discovery of Platinum in Spain

According to a detailed account published in *Revista Minera Metalúrgica y de Ingeniería*, Madrid, Nov. 1, 1915, the presence of platinum has been definitely determined in some parts of the Ronda Mountains, in the province of Malaga, Spain.

In the course of a petrographic study of the rocks of the district by Domingo de Orueta, it was noticed that some of the rock bears a close resemblance to the platinum-bearing strata of the Urals, in Russia. The matter was followed up by careful sampling, during which platinum was actually found. The ground was then explored by boring, and the borings were washed. By this means pellets of platinum were found, together with the characteristic black sands, magnetite, chromite, etc.

Mining and Military Engineers Past and Present

The emergencies of the present European war have been of such constant occurrence and have been met with such brilliant fortitude, especially by the Royal Engineers, that they have been given a glowing tribute by Sir John French in a dispatch dated Oct. 15, in which he calls special attention to the splendid work carried out by those "companies officered largely by *mining engineers*[1] and manned by professional miners."

I have on previous occasions called your Lordship's attention to the admirable work of the corps of the Royal Engineers This work covers a very wide field, demanding a high standard of technical knowledge and skill, as well as unflagging energy.

The necessity for skilled labor at the front has been so continuous that Royal Engineer units have frequently been forced to forego those periods of rest which at times it has been possible to grant to other troops; but, in spite of this, they have responded loyally to every call on their services. Notwithstanding the heavy casualties sustained by all ranks, the esprit de corps of the Royal Engineers is such that the new material is at once animated by the same ideals, and the same devotion to duty is maintained.

I desire to call your Lordship's attention to the splendid work carried out by the Tunneling Companies. These companies, officered largely by mining engineers and manned by professional miners, have devoted themselves whole-heartedly to the dangerous work of offensive and defensive mining, a task ever accompanied by great and unseen dangers. It is impossible within the limits of a dispatch to give any just idea of the work of these units, but it will be found, when their history comes to be written, that it will present a story of danger, of heroism and of difficulties surmounted worthy of the best traditions of the Royal Engineers, under whose general direction their work is carried out.

It did not take the present war to bring the necessity of engineering knowledge in warfare to the attention of the commanding generals. Our own Engineer Corps, about which so much is now being heard in connection with its augmentation in time of trouble by a reserve of civilian engineers, came into being as an arm of the service in 1846.

The conspicuous services performed in the Mexican War by engineers, which Maj. Wildurr Willing, in "Professional Memoirs," says "must ever be a source of inspiration and profitable study to their successors in that branch," are interestingly summarized in the "International Military Digest."

The need for engineer troops was first emphasized when Taylor's pursuit of the Mexicans on Texas soil was halted by the lack of pontoon equipage with which to cross the Rio Grande. Authorized on May 15, 1846, the first engineer company was organized under Capt. A. J. Swift and reached the Rio Grande on its way to the front with Wool's army in October. The river, 800 ft. wide at this point, was crossed by means of a flying bridge. Means for other difficult crossings had to be improvised during this march. In the advance on Victoria the next month, the "pick and shovel brigade" rendered the road practicable for the train.

During Scott's operation at Vera Cruz, the engineer company was employed in opening up new roads, destroying the underground aqueduct that supplied the city, locating and constructing (assisted by details from the line) the batteries and siege works, and later in mapping this captured city. Colonel Totten was Scott's chief engineer during this time. When the column started for Mexico City, the company marched at the rear; after Cerro Gordo and the resumption of the advance from Puebla, it had moved up to the forefront, and with the best of transportation. Among its important duties were the improvement of the roads, by which Scott turned the city to the south; participation in the attack at Padierna and the surprise of Valencia's army; the construction of batteries that bombarded Chapultepec; and an active rôle in following up that victory and entering the city. The company officers at this time were Lieuts. G. W. Smith and G. B. McClellan.

All told, there were 14 engineer officers in the war, of whom were in the Topographical Engineers. Especially conspicuous were the services of the individual officers on staff duty. Both Taylor and Scott used these officers constantly in reconnoitering the enemy's position; nearly every plan of campaign was based upon their reports, and the attacking columns were often guided by these same officers. Thus Mansfield at Monterey, Lee and Johnston at Cerro Gordo, Beauregard and Tower before Mexico City, and a dozen others made notable performances. It was a striking tribute to the engineers that from their number were chosen five of the council of 12 that decided which point of the city fortifications was to be attacked.

In a recent lecture Prof. R. M. Johnston, Harvard's great military scientist, discussing old and new theories of battle, stated that geometry was first called in to the general's aid in the eighteenth century and it soon became his sovereign master. The eighteenth century thus first brought the engineer into prominence, and he was constantly consulted, at that time, on all questions of time, distance and formation. He was not, however, given any prestige, but was kept as the cook in the kitchen, to make the broth which the pompously arrayed butler would serve. The wars of the Revolution gave the engineers a somewhat better chance, and in 1791 came the founding of the Ecole Polytechnique. The development of artillery was the chief factor that made for the change of old theories at this time, and it was the artillery that produced Napoleon.

Sulphuric-Acid Supplies in France and England

The requirements of the French munition factories for sulphuric acid have become so important that it has been questioned, says *Le Phosphate*, whether the whole of the French output should not be reserved for the state instead of the 20% as at present. Happily it has been remembered in time that the needs of agriculture are as important as others from the point of view of the war, and it has been finally decided to reserve the quantities necessary for the manufacture of superphosphate.

Our contemporary estimates that this will give from 300,000 to 400,000 tons of superphosphate—little enough in comparison with the amount used before the war, but now perhaps sufficient in view of the shortage of labor in the country districts.

In addition to the foregoing translation, the *Chemical Trade Journal* prints the following: Everywhere it is complained that the color difficulty grows greater, says the *Dyer and Calico Printer*, and the government consumption of sulphuric acid is freely given as the cause of the shortness of the supply of British-made colors. Dyers feel the shortage more acutely than anybody else, but the consequences are felt, of course, by everybody needing colored yarn or goods, so that there is a continual buzz of dissatisfaction. It may be hoped impartially that the arrangements for promoting the production of sulphuric acid are upon a scale commensurate with the new arrangements that are being made for its consumption. Very soon sulphuric acid will be wanted in quantities largely exceeding a consumption that is already tremendous, and a surplus beyond the needs of the explosives trade is indispensable if there are to be dyes in any abundance.

New Coal Fields Are Reported near Manchuli on the Chinese Eastern R.R. in Manchuria. Their extent is now being investigated.

Ashio's Copper-Smelting Works at Honzan, Japan

SYNOPSIS—The products of the Ashio Copper Mines are smelted at Honzan, about 100 mi. north of Tokyo. The coarse first-grade ores are charged directly to the blast furnaces; the concentrates and fines are first briquetted or sintered in pots. Acid-lined barrel-type converters are used. A new dust-settling system was completed in September.

The Ashio Copper Mines, of Japan, formally opened on Sept. 27, 1915, its new dust-settling system at the Honzan smelting works, near Ashio, in Tochigi Ken, on the island of Hondo. The Ashio company has in this district a concession of about 4,000 acres. The three principal mines are Honzan, Kotaki and Tsudo, which are situated about three miles apart. Each has its own ore-dressing plant, but the smelting for all the Ashio mines is done at Honzan. The blister copper is refined at the Nikko Copper Works, about 20 mi. northeast of Ashio.

Furukawa & Co., which owns the aforementioned properties, is the most important mining company in Japan. It was established over 40 years ago by the late Ichibei Furukawa and controls seven groups of copper mines, two silver mines, one gold mine, one lead mine and several collieries, the company's concessions embracing 54,000 acres. To summarize briefly, it has 9 offices, 2 copper works (Nikko and Amagasaki), 20 mines, an annual production of 15,000 tons of copper, 200,000 tons of copper ore and 550,000 tons of coal, besides lead bullion, silver ore, zinc ore, etc. It employs about 22,000 men, who are supervised by 1,600 officials.

Chief Copper Mineral Is Chalcopyrite

The ore deposits of the Ashio group of mines consist for the most part of veins transversing Tertiary liparite (rhyolite) and, to some extent, the Paleozoic sediments of the district. The principal Paleozoic rocks are slate, quartzite and limestone. The liparite is a volcanic neck erupted through the Paleozoic and is more than two miles in diameter. The chief constituents of the veins are chalcopyrite and pyrite, with frequently arsenopyrite, blende, galena and pyrrhotite. Occasionally, bornite, chalcocite, cuprite, malachite, pisanite, azurite and native copper are all found in the oxidized zone. Rarely, native bismuth, bismuthinite, wolframite,

fluorite, vivianite, ludlamite and apatite are found. As gangue, chlorite, quartz and clay are common, with calcite occurring occasionally.

Overhand stoping is generally adopted at the Ashio mines; underhand stoping and *Nukibori* (special working for richer part of vein) are rarely used. Both hand and machine drilling are done. Among the machine drills are: Water Leyner, Ingersoll-Sergeant, Sullivan, Flottmann, Little Wonder and others. The ores in the mines are usually classified into two kinds—first-grade and second-grade. The former is rich ore sorted underground and usually averages 12% copper. About 214 tons of first-grade and 1,263 tons of second-grade ore comprise the daily output from the three mines, according to a booklet published this year by the Furukawa company, from which many of the data in this article were obtained.

Blast Furnaces and Acid-Lined Converters

Smelting is done in four blast furnaces, the matte being converted in three stands of acid-lined barrel-type converters. The ores received at the smelting works are

EXPANSION JOINT IN ASHIO DUST CHAMBER

classified into five kinds. These include lump ore, fines, concentrates, slimes and cement copper. The output from the concentrating plants amounts to about 300 tons daily, with an average copper content of about 11%. Cement copper is obtained from two sources, the mine water and the waters draining from the old dumps. The copper is precipitated on scrap iron, the daily production amounting to about 2.3 tons averaging 66% Cu. The smelting plant treats annually about 100,000 tons, with an output of over 11,000 tons of copper.

The lump ore is charged to the blast furnaces in the raw state, and the fines are either sintered or briquetted. Most of the fines are sintered in pots, of which there are 8, placed in two rows and used alternately. The pots are conical, hold about 11 tons of ore and have false bottoms through which the blast enters. After sintering, the mass is cooled and crushed into suitable sizes for charging to the blast furnace. Three briquetting machines are at work, with an output of 40 tons of briquettes in 24 hr.

The blast furnaces are of the rectangular water-jacketed type, each 42x160 in. at tuyeres. The height from the center of the tuyeres to the feed floor is 8 ft. 6 in. Each furnace has twenty-four 4½-in. tuyeres. The forehearths are 12 ft. in diameter inside and 4 ft. in height, and are lined with magnesite brick. The blast for the furnaces is supplied at 2-lb. pressure by a Roots No. 8 blower and turbo-blowers. Each furnace smelts about 90 tons per 24 hr., and the grade of the matte averages 40%. The composition of the slag is: Silica, 39%; iron, 25%; lime, 19%; alumina, 9%; copper, 0.2%.

The matte is converted in hydraulic-tilting shells, of which six are provided for the three blowing stands. The shells are 72 in. in diameter and 100 in. in length. Blast is supplied at 10-lb. pressure by two horizontal blowing engines driven by electricity, and also a vertical engine driven by water power. The lining material is decomposed liparite found in the vicinity. The converters produce about 65,000 lb. of blister copper per day, which is cast into 70-lb. bars or anode plates. The analysis of the blister copper is: Cu, 99.077%; Au, 0.0003 oz.; Ag, 0.1065 oz.; As, 0.029%; Bi, 0.006%; Fe, 0.052%; S, 0.028%; Se and Te, 0.038%.

New Flue System Finished This Year

The smoke from the smelting plant is passed into a Cyclone dust catcher by means of fans. Having precipitated most of the suspended dust therein, the fume enters the common flue and proceeds to the fume-precipitating chamber, where it is condensed and precipitated by the Rösing wire system. The gases escape through the chimneys after being diluted with fresh air forced in by the fans. The provision of four stacks is noteworthy, and the general arrangement of the flue system may be noted from the accompanying engravings, showing the flue system in plan and elevation, as well as presenting several interesting exterior views. It will be observed that the new flue system involved a large amount of concrete construction, which, judging by the general view, has been well executed. Another interesting illustration is that of the ceremony celebrating the opening of the flue on Sept. 27. Another view shows the fans that supply extraneous air at the base of the stacks for diluting the flue gases. The gases as discharged into the air contain about 3% by volume of SO_2. Care is also taken to prevent damage by the waste products of the precipitating and dressing plants. The tail water from the precipitating tanks and the slimy water from the ore-dressing plants are treated with milk of lime after they have passed through the settling pond.

Power for the Ashio copper operations is supplied from the Hosoo hydro-electric power plant, built in 1905, about 12 mi. from Ashio. This plant develops 2,500 hp., but it is being enlarged to 10,000 hp. for the purpose of supplying both the Ashio Copper Mines and the Nikko Refining Works. Besides the main power plant

there are several auxiliary electric- and two water-power plants, near Ashio. The consumption of power in the various departments of the Ashio Copper Mines is as follows: Mining, 2,550 hp.; ore dressing, 800 hp.; smelting, 2,200 hp.; miscellaneous, 600 hp.; total, 5,150 hp. The Ashio district has rail communication with Tokyo, about 100 mi. to the south, by means of the Ashio Ry. and the Imperial Government Ry.

Flotation at Globe-Miami, Ariz.

SPECIAL CORRESPONDENCE

The Globe-Miami district of Arizona is now, and has been for some time, the scene of many important and interesting developments in flotation. The principal mills are operating either on a commercial scale or experimentally, and some profitable commercial results are being obtained. At the Inspiration mill the ore is dumped into a large steel bin. For each of the 18 sections of the mill there is a gate and chute at the bottom of the bin, and underneath the chute a Stephens-Adamson conveyor-type feeder that drops the ore upon an inclined conveyor belt, carrying it up to the feed box. Here half goes to the first and half to the second 8x6-ft. Marcy ball mill of each section. Two 225-hp. motors operate the ball mills in each section. These mills are set end to end, with two Dorr duplex classifiers between them, one pointed toward the first ball mill and the other toward the second.

From the feeding box the ore enters the first Marcy mill, the flotation oil and mill water being added at the mill feed box. The ground pulp emerging flows around the mill and through one of the Dorr classifiers, where the oversize is pushed up to the feed box of the second Marcy mill, thus completing half the closed circuit. Each Marcy mill in each section receives the coarse from the classifier of the other Marcy mill, together with a fresh supply of ore from the feed box, and the flotation oil and mill water.

The flotation oil is contained in a headless steel drum and is drawn out by a miniature bucket elevator, the bucket being carried upon two continuous chains and running over a toothed head wheel driven by a pawl. The mechanism is similar to some of the usual types of zinc-dust feeders.

The thickness of the undersize from the Dorr classifiers is controlled by a float operating the valves, controlling, through electrically operated mechanism, the flow of water into the slimes compartment. Seven sections of the mill are now complete, and the ball mills of nine sections are ready to work. In the seven sections in operation there are three different systems of treatment below the Dorr classifiers.

DIFFERENCE IN SECTIONS AT INSPIRATION

In sections 1 and 2 the undersize from the Dorr classifiers runs to a set of 12 Callow flotation machines, the concentrates then going to a set of four Callow cells for cleaning. The clean concentrates run by launder through the concentrate-collecting system, while the tailings are returned by a centrifugal pump to the first Callow cells for retreatment.

The tailings in the first group of Callow cells run to a drag classifier of the Esperanza type. The slimes overflow and are combined with flotation oil in a collecting box beneath the classifiers. The sands run into two hydraulic sizers, each of which has six pockets, and in each pocket there is a pair of Deister baffle-cone classifiers. Fine slimes run into a compartment at the end of the sizers and then to the collecting box under the drag classifiers. Material in this collecting box is elevated by two centrifugal pumps, each carrying half the stream, to a separate group of 12 Callow cells that make clean tailings and concentrates, which go to the same four cleaning cells that clean the concentrates from the first group.

The products from the two pairs of Deister cones making the coarser classification products go together to one Deister double-deck simplex sand table. Each of the other pairs of cones feeds one double-deck table, so that six sizes are made for table treatment; requiring eleven tables per section. The tables make clean concentrates, middlings and tailings, but the middlings now flow off into the tailings launder. A middlings treatment will be undertaken later when the work of completing the mill will permit.

In sections 3 and 4 the flow differs in that the pulp from the Dorr classifiers goes to two sets of flotation machines of eight cells each, while the pumps and collecting boxes return to only one 8-cell machine; otherwise the flow is the same as in sections 1 and 2.

SECTIONS WITHOUT CALLOW MACHINES

In sections 5, 6 and 7 no Callow machines are used, but Inspiration cells, devised at the property, are at work. The pulp from the Dorr classifiers goes to two machines of 16 cells each, the concentrates from which go to a similar set of two 6-cell machines and make a clean and finished concentrate, the tailings being returned by centrifugal pumps to the feed box of the first group of 16-cell machines. More flotation oil is added at the tailings compartment of the cleaner cells. The tailings from the 16-cell machines flow to a drag classifier, which delivers the coarse material to the Deister sizers, and treatment of the products from there on is the same as has already been outlined. The slimes overflow from the drag classifier, together with the slimes from the slimes compartment of the hydraulic sizers, runs to waste from the collecting box, instead of being pumped back for further treatment, as is the case in sections 1, 2, 3 and 4.

The main tailings launder leads to three 60x10-ft. Dorr thickeners, the overflow going to a large sump from which it is pumped back to the new water-storage tanks. The thickened underflow goes to the tailings. The present set of three thickeners is not of sufficient capacity to handle all the tailings, and seven more are to be added—three 100x10 ft., three 80x10 ft., and one 60x10 ft.

HANDLING THE FLOTATION CONCENTRATES

All concentrates launders converge to a group of 60x10-ft. Dorr thickeners, the overflow from which goes to the same sump as the overflow from the tailings thickeners. The thickened underflow is raised by four bucket elevators to 12x12-ft. Oliver filters, the cake being scraped over a steam-heated plate and the dewatered concentrates dropping to a conveyor belt. They are then elevated to a steel concentrate-storage tank under which the concentrate cars can be started and the concentrates drawn into them for haulage to the smeltery.

The Inspiration flotation machine is built up of 16 compartments, each about 30 in. long by 42 in. wide, the

partitions between cells being so arranged that the underflow of the first cell flows successively through all the others, in this respect somewhat resembling the flow through the Minerals Separation machines, but the flow is by gravity, or displacement, there being no agitators to lift the pulp. The cells of the 6-cell cleaner machine are smaller than in the 16-cell rougher. The air pipes are above the machines, and a branch from the air main runs vertically downward into each cell, instead of entering from below, as in the Callow cell.

The Globe-Miami district affords some interesting comparisons now in milling practice, in the procedure followed at the Miami, Inspiration and Old Dominion mills. In the Old Dominion the ore differs from that treated in the Miami and Inspiration mills. A rougher, or bull jig, makes clean concentrates on a mixed feed, the concentrates being about ¼-in. size. The other jigs, together with a rougher or bull jig, recover the larger part of the concentrates produced. A Minerals Separation machine of 16 compartments treats slimes, and some Callow cells have been installed for experiment. Flotation here produces a sort of end product—that is, only a small portion of the entire mill concentrate. Hardinge mills for regrinding and Symons disk crushers in the coarse-crushing department are used, the only rolls being those recrushing the bull-jig tailings.

At the Miami mill, rolls are used both in the coarse-crushing department and in the mill proper, working on the feed from the mill ore bins and the coarse product from them going to the Hardinge mills. Callow flotation cells are used for the final treatment of slime, elevators raising the material, while the flotation oil is added at the launder running to the elevators. A Pachuca agitator was used for emulsifying the oil, but has been found unnecessary. The slimes from one section are treated in a group of Callow cells, the concentrates from two sections being cleaned in a group of four similar cells.

At the Old Dominion mill the 12 head cells of the Minerals Separation machine make a finished concentrate, the last four cells' overflow product being returned by the elevators to the head end of the machine.

At the Inspiration mill the flotation cells treat all the pulp and float some copper-sulphide grains even up to 40-mesh size, and the larger part of the concentrates are made by flotation. The tables recover a lower grade and work on material that has passed through the first, at least, of the flotation cells. The flow of pulp is direct, there being no regrinding once the material leaves the Dorr classifiers. There are no elevators in the mill except those lifting concentrates, and rolls are eliminated entirely. The arrangement of a mill treating 14,000 tons daily is remarkably compact. The plant probably covers less floor space per ton of capacity than any other mill.

The Principal Ore of Antimony is the sulphide, stibnite, which contains, when pure, 71.4% antimony, according to the Mackay School of Mines "Bulletin." Stibnite is a lead-gray metallic mineral with a high luster, commonly occurring in aggregates of columnar or bladed crystals and radiating groups, and more rarely in massive granular form. It may be distinguished from galena, which it resembles in color and hardness, by the fact that galena always has a cubical cleavage. Moreover, when stibnite is melted before the blowpipe, it fuses easily, gives off copious white fumes and produces a brittle button, whereas galena gives off scanty fumes and a malleable button. In this respect it resembles arsenopyrite, but the latter mineral not only gives off heavy white fumes, but also a strong garlic odor.

Operations at Old Dominion

GLOBE CORRESPONDENCE

At the Old Dominion smeltery at Globe, Ariz., a third blast furnace has been blown in to smelt the increased tonnage of ore now coming to the plant. The greater part of the tonnage now comes from the Old Dominion and United Globe mines and as concentrates from the mill. The Arizona Commercial is supplying ore regularly, and there is a growing tonnage coming in from custom and leasing operations. The flue dust and flotation concentrates are being briquetted prior to smelting, while table and vanner concentrates are mixed with plaster and molded into briquettes. The Old Dominion blast furnaces are running on a charge containing a high proportion of fines.

At the Old Dominion mill 700 tons of ore is being treated daily, the main recovery being effected by jigs. The jig tailings are reground in Hardinge mills, classified and treated on tables or vanners. Slimes are treated in a 16-cell Minerals Separation machine and in some recently installed Callow flotation cells. Coal tar is to be used in the flotation machines in the place of the higher-priced pine oil and creosol. A coal-tar storage tank is now being erected at the side of the mill.

A total of about 1,000 tons per day is now being hoisted from the mine, most of it coming from the east and west sides of the 12th, 14th and 16th levels. The ore is dumped into storage pockets in the station floors and is drawn automatically into the skips and hoisted to surface. What waste is not used for filling underground is also raised in skips; very little is now raised in cars. The 18th level has been unwatered, and the Aldrich pumps on that level are running again. This level has just been recovered after the flooding of the lower levels last March. The pumps on the 18th level are motor-driven, and the armatures had to be rewound after having been under water for six months. These pumps raise 1,200 gal. per min. from the 18th to the 16th level, where the main steam-driven mine pumps are situated. A total of 6,000,000 gal. daily is now being raised, but after the flooding last March more than 12,000,000 gal. was pumped daily. Sinking from the 12th to the 16th level of the Kingdon shaft is to be started soon, and development work is under way to explore undeveloped parts of the lower levels.

California Oil in October

SPECIAL CORRESPONDENCE

Petroleum production in California in October was 7,675,146 bbl.; shipments amounted to 8,599,681 bbl. Total stock on hand Nov. 1 was 57,879,376 bbl., showing a decrease in October of 924,535 bbl. The intentional curtailment of production in the present year, owing to the European war's retarding the marketing industry, has reduced the stocks on hand from 58,259,119 bbl. on Jan. 1, 1915. The average daily production in October was 3,251 bbl. more than the average daily production in September. For the same two months in 1914, the increase in October over September was 34,256 bbl. The shut-in production remains about the same as in September—18,000 bbl., of which 12,000 bbl. are in Coalinga field. New wells completed in October netted 4,220 bbl. of new production daily.

Drill Steel and Its Treatment

By E. M. Weston*

SYNOPSIS—Of the steels tested those gave poorer results that were lower in carbon and higher in sulphur and manganese. Alloy steels did not give as good results as ordinary steels. The larger the steel the lower should be the carbon contents. Steels were found to improve after being sharpened several times, probably owing to the effect of hammering.

During 1910-11 the Mines Trial Committee carried out a number of interesting investigations. Though some short references have appeared, no summary of these investigations and the conclusions reached has ever been published. They are of interest to mining engineers in all parts of the world. The first investigation was directed to discover by analysis and practical trials what was the best steel for bars of various sizes and the best method of heat-treatment to give them. Following is a list of the terms used in the report and their meaning:

Alloy Steels—By these is meant steel containing chromium, vanadium or tungsten and perhaps aluminum.

Carbon Steels—These are ordinary steels with manganese and a little aluminum.

Cutting Off—This refers to remaking bits flaked or burnt. It generally takes 40% longer time to sharpen such a bit.

Scaling—This occurs in the forge and is due to excess of air, which caused oxidation of the steel while heating.

Chipping—This term refers to the breaking off of flat scales not more than $\frac{3}{16}$ in. thick when the bit is drilling. Not more than 10% of properly sharpened bits should chip, showing that the right hardness has been obtained. Chipping does not greatly influence the drilling speed.

Flaking or Splintering—This is the breaking off of large irregular pieces and is due to very hard ground or to an excess of silicon, sulphur, carbon, manganese or some alloy. It may also be caused by faulty heat treatment.

Fire Cracking—This is due to bad steel, especially that containing excess of sulphur, or, in the case of high-carbon steel, to rapid or irregular heating.

Water Cracking—This is the cracking of heated steel when plunged in water and is due to very high carbon contents or notably to excess of phosphorus or to irregular heating.

Soundness of Steel—This refers to its freedom from occluded gases, slag and fissures.

Tempering—When heated steel is hardened by plunging it into cold water, it is often too hard and brittle. This defect is diminished and the steel made tougher at the expense of hardness by reheating it to some temperature about 200° to 300° C. for a short time. This operation is generally necessary in the case of high-carbon steels, but with ordinary steel of lower carbon contents it can be dispensed with by raising the temperature of the water in which the steel is quenched.

Recalescent, or Critical, Points of Steel—On heating a piece of rock-drill steel slowly and observing its rate of rise of temperature with a pyrometer, a halt will be observed to occur between 700° and 750° C., denoted by the sign A_c. On slowly cooling, a similar halt is observed, usually 30° C., below A_c; this is denoted by A_r. The halt at A_c is due to the heat being expended in producing microscopic structural changes, the steel being converted into martensite. This structure is retained if the steel is suddenly cooled and the steel is hardened. In ordinary mine work this process is known as tempering.

If the steel be slowly cooled it becomes soft, or annealed, owing to the change of the martensite into pearlite and ferrite when the steel contains less than 0.9% C. or into pearlite and cementite when carbon is over 0.9%. Ferrite is very soft, pure iron. Cementite is hard, brittle carbide of iron. Pearlite is a mixture of the two. The points A_c and A_r are called the recalescent or critical points of steel.

Methods of Conducting the Tests

The steels tested were 1½-in. cruciform, 1-in. and ⅞-in. octagon, and were used in $2^{3}/_{4}$-in. sloping drills. They were given the necessary heat treatment, and the bits were carefully measured, inspected and weighed before and after being used. The distance drilled was noted and sometimes the drilling rate of speed. Various marks were allotted for merit, and the question of price was considered. Chemical analyses were made of the various steels, and a fair idea of the class of steel most suitable for work in the hard quartzites of the Rand, and inferentially in hard ground elsewhere, was obtained.

First, with regard to loss of reaming efficiency with ⅞-in. octagon drill steel, a comparison of the steel giving the best and worst results showed:

For the Best		For the Worst	
Carbon	0.770%	Carbon	0.650%
Silicon	0.110%	Silicon	0.100%
Sulphur	0.010%	Sulphur	0.020%
Phosphorus	0.029%	Phosphorus	0.026%
Manganese	0.290%	Manganese	0.380%

This showed lower carbon contents and greater sulphur and manganese in the poorer steels.

With regard to loss of weight through wear, the results showed:

For the Best		For the Worst	
Carbon	0.800%	Carbon	0.640%
Silicon	0.070%	Silicon	0.180%
Sulphur	0.012%	Sulphur	0.020%
Phosphorus	0.028%	Phosphorus	0.032%
Manganese	0.270%	Manganese	0.430%

This shows a similar result and the bad effect of phosphorus.

The general results of the tests were as follows:

A. Although some of the alloy steels have shown excellent drilling results and are not costly in steel consumption, not one of them is equal to the rest of the ordinary carbon steels. With alloy steels, a uniform composition is harder to obtain than with carbon steels. The former have more tendency to overheat and are more difficult to weld.

B. Best 1½-in. cruciform steel: Steel having carbon contents above 0.75% was rejected, owing to the difficulty of welding it. It was also found that as a general rule the larger the size of steel the lower should the carbon contents be, as the difficulty of equal or regular heating and quenching increases with the size of the steel. The best

*Union Club of South Africa, Johannesburg, South Africa.

steels of this size had a composition: Carbon, 0.66%; silicon, 0.09%; sulphur and phosphorus, 0.036%; manganese, 0.28%.

C. Of the 1-in. octagon steel the best had a composition of: Carbon, 0.69%; silicon, 0.09%; sulphur and phosphorus, 0.036%; manganese, 0.30%. Of the 7/8-in. octagon steel the best had a composition of: Carbon, 0.72%; silicon, 0.09%; sulphur and phosphorus, 0.035%; manganese, 0.27%.

Bits made from sections larger than 1½-in. cruciform are much larger, and in rapid working they tend to overheat if the interior is properly treated, thereby decarbonizing; quenching is also difficult. These steels should contain from 0.60% to 0.65% C. In all these steels the maker should be allowed to use aluminum as a purifier if not more than 0.10% is left in the finished steel. The best steels were Swedish bessemer, crucible, openhearth (mostly) and electric crucible. Steels were found to improve after being sharpened several times, probably owing to the effect of hammering on the grain of the steel.

Particulars of the Heat-Treatment

Usually, on the Rand, all drills except those of hollow steel are heated but once for a long distance from the bit. They are rapidly sharpened, they are not gaged and are quenched without reheating. This method tends to overheating, to the decarbonization of the steel and to irregularities in the gage. The steels of the compositions already quoted can be quenched off the anvil without tempering. The temperature of the quenching bath should be between 18° and 26° C. Drills should be properly cleaned and should be slowly heated. Hand steel requires 5 min., medium steel 8 min. and large steel 12 min. This heating should preferably be done in an oil furnace, as overheating is very liable to occur with coal fires, especially when watched by natives. The drills should be heated to a bright orange-red heat (about 1,050° C.) for 1½ in. for hand steel, 2 in. for medium sizes, 3 in. for large steel, and be thoroughly and regularly heated through the mass of the steel. The heated drill should be forged until it cools to a dull-red color, about 600° C. With hand sharpening, this should take from 45 to 60 sec. The bit should be at once reheated to a bright-red color, about 950° C. It should then be finally sharpened and carefully gaged until a cherry-red color, about 750° C. This should take another 45 sec. Bits of 1½ in. cruciform steel, or larger, are quenched by standing them on a knife-edge ½ in. to ⅝ in. below the surface of the water. Smaller bits are plunged vertically, moved about for a few seconds and left standing on a false bottom. With more rapid machine sharpening, except with hollow steel, one heat should be sufficient, as gaging is automatically done.

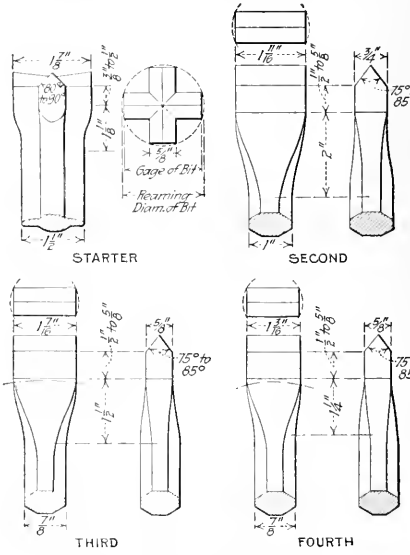
Quenching tanks should be supplied with cold water at the bottom at three places and should have a false bottom, as well as frame and knife-edge below water level. They should be fitted with an indicating thermo-telegraph thermometer, so that the necessary temperatures can be maintained. Usually the bath is allowed to be too cold in the morning and to get far too hot later in the day. If steel is quenched at above 800° C., the grain gets coarser, the tensile stress and the elongation both become less. The higher the carbon contents of the steel, the higher should be the temperature of the water for quenching. If, however, it requires a higher water temperature than 35° C., the carbon content is too high for rock drills unless tempering is employed. Shanks of drills may be tempered by leaving them for a minute in a molten-lead tank 1 in. deep, covered with ashes; if somewhat harder shanks are required, a little tin may be added to the lead.

The loss of weight per inch drilled with the very best steel was 0.4 gram, and good steel averaged about 0.6 gram, costing about 0.015 penny. The total cost of solid steel and its sharpening is 6% of stoping costs of 4s. to 6s. per ton. With hollow steel it is about twice as much. The best steel could be bought in Johannesburg at from 4d. to 4½d. per lb. The loss of steel per inch drilled was found to be the same with all three sizes of steel experimented with.

Design of Drill Bits Adopted

The style of drill bits adopted has been already illustrated in the *Journal*, but it deserves further notice.

It was stated that chisel bits were found by experiment to be the fastest drillers and this was claimed to be due to the facts that they occupy only 50 to 63% of the hole



BITS USED IN STEEL TESTS BY MINE'S TRIAL COMMITTEE

and that they allow the escape of mud better. This reason is open to question. The four square reaming edges, of the depth shown in the sketch, were adopted. I have seen such a design of bit recommended for hammer drills, but it is opposed to all accepted theories of the correct formation of the wings of piston-drill bits. One might suppose that it would prejudice the rotation of the drill in the hole, but the fact remains that the experimenter got most excellent results in hard ground from this design, and I commend it to the attention of mining engineers elsewhere. The next point of interest was that the experimenter showed that by using gaged steel, more carefully sharpened, and drilling larger holes, it was possible to reduce the drills used per fathom broken from 35.8 to 26.6. Gaging may take 25 to 30% more time and add to the cost of sharpening, but it pays for itself. The

reaming diameter of the holes drilled was greater than the nominal gage. The experimenter says of these square reaming edges: They should be hardened for ¾ of their length. (1) They help by reaming out the hole to keep it from decreasing in diameter too rapidly. (2) They prevent "wobbling" of the drill in the hole and thus preserve its cutting edge and reduce wear and tear on machine. (3) The drill passes slips or heads better.

The thickness of the bit should be kept about ⅝ in., otherwise the reaming diameter is increased too much. There was a great difference in gage used; $\frac{3}{16}$ in., ¼ in., and ¼ in., as shown by the following table:

	Starter	Second	Third	Fourth
Inches drilled	13.4	22.1	23.4	21.5
Drill rates, in. per min.	1.58	1.77	1.97	2.14
Gaged bit	$1^{13}/_{16}$ in.	1¾ in.	1⅝ in.	1⅜ in.
Reaming diameter	1.95 in.	1.79 in.	1.54 in.	1.34 in.
Loss of reaming diameter	0.09	0.18	0.17	0.15

The experimenter remarks that it would be possible to reduce the gage. This is evident. Owing to vibration of the drill in the hole, the hole bored is always 0.05 larger than the bit, so that all the difference necessary between different steels would have been about 1/6 in., or 0.17 in. This would have meant an increase of drilling speed equivalent to starting the hole at about 1⅝ in. instead of 1⅞, probably 10 to 15%. This is a matter that received far too little attention, owing to the mistake of using the same steel to drill dry holes as to drill wet holes.

Another series of experiments showed the benefit of gaging steel. The ordinary run of mine steel was found when new to differ from 0.09 in. to as much as 0.17 in. from the proper gage, while the gaged steel hand-sharpened was found to differ only between 0.01 and 0.03 in. from standard.

These experiments undoubtedly were most valuable and pointed out the way to a great increase in efficiency in stoping on the Rand. Yet, except in the case of perhaps one or two mines, the results have received no attention whatever. Machine drills are, when sharpened by hand, as badly sharpened as ever, though the quality of the supply of drill steel itself has been standardized very well.

Canadian Mining and Exploration Co. Liquidates

The Canadian Mining and Exploration Co., a $5,000,000 concern organized in 1912 by a number of wealthy men in New York and Canada to investigate and exploit mining properties, is to be dissolved and the capital returned to the subscribers. Half of the $5,000,000 was paid in.

The directors investigated about 1,500 mining propositions without finding one that was considered worthy of development. In the meantime the capital paid in has been carried in interest and dividend-paying securities. These investments, which cost $2,231,000, are now valued at about $2,185,000, but the income received will enable the company to repay subscribers in full, with perhaps 5% interest on the money. All of the assets have been liquidated.

Ontario Mineral Output

In issuing its statistics on the mineral output of the Province of Ontario for the first nine months of 1915, the Ontario Bureau of Mines makes the following comment:

The Sudbury mines are being worked to their maximum capacity, and the production of nickel for the nine months nearly equals the largest previous output for a full year. Over 75% of the output is made by the Canadian Copper Co., but the operations of the Mond Nickel Co. are now more extensive than formerly and its output has correspondingly increased. The yield of copper is also much greater than in the corresponding period of 1914 and nearly equals the total output of that year. It was all contained in the Sudbury mattes. Metallic nickel and cobalt are now produced from the silver ores of cobalt by the smelters at Deloro and Thorold. The metallic-nickel output equaled 98,216 lb. and the cobalt output 24,962 lb., for the nine months. The trade in cobalt and nickel oxides has been heavily affected by the war, and the quantities shipped were much below those of the corresponding period of 1914. Efforts are being made to put the molybdenite industry on a commercial basis.

Hydraulicking at Surigao, P. I.

The most important hydraulic-mining operation in the Philippines was started in 1914 by the Cansuran Placer Co. in the Province of Surigao on the eastern coast of the Island of Mindanao. The company began hydraulicking toward the end of 1914 at a point from 10 to 12 km. south of the town of Surigao on property leased from the Cansuran Mining Co. According to the report[1] of Wallace E. Pratt, chief of the Division of Mines, American prospectors were quickly attracted to this region following American occupation, and C. A. Briggs, E. O. Parker and R. W. McCullough obtained possession, through location and through the purchase of a Spanish grant, of the placer properties on Cansuran Creek and of lode deposits, which through the organization of the Cansuran Mining Co. they have retained.

R. Y. Hanlon, upon whose report the placers were leased by the Cansuran Placer Co., made a series of 181 tests by sinking shafts through the gravel to bedrock and panning regular vertical sections from surface to bedrock. He delimited in this manner several blocks, near each other although not contiguous, with an aggregate area of 131 hectares. Over this area he obtained an average value of 57 centavos per cubic meter, the average depth to bedrock being 3.5 m. All this ground is at such an elevation that water for hydraulicking purposes can be brought to it under a head ranging from 40 to 100 m.

Hydraulicking is now in progress on the ground tested by Mr. Hanlon. Water is obtained from Tuganaan River and is conveyed a distance of about 1.8 km. by ditch, flume and pipe line. According to the engineer's estimates, 1,000 miner's inches (0.70 cu.m. per sec.) of water is available. The flume is 1.2 m. wide, has a fall of 1.7%, and is built of native wood. At present the water is stored in a reservoir which is about 46 m. above the monitors. Another large reservoir is under construction which will afford a head of about 100 m.; water can also be drawn from the flume directly into the pipe line under a head of about 100 m. The main pipe line is 0.61 m. (24 in.) in diameter, the branches to the monitor being reduced appropriately. Two 6-in. monitors and one 7-in. monitor are in place, although there is insufficient water now to operate all of them continuously. The sluices are 73 m. long, 1.5 m.

[1] "The Mineral Resources of the Philippine Islands for the Year 1914." Division of Mines, Bureau of Science, Manila, P. I.

wide and are riffled with hardwood blocks 0.3 m. (12 in.) square, set with a space of 2.5 cm. (1 in.) between cross tiers. There is at present a length of about 100 m. of bedrock sluice ahead of the sluice boxes.

The company has installed a small air compressor and uses three hammer drills for breaking up the larger boulders. A logging engine and movable cableway serve to remove rocks too large to go through the sluices. A small Pelton-Doble wheel on a separate pressure line furnishes power for lights, refrigerating plant and a small sawmill with which the timber cleared ahead of the giants is sawed into marketable lumber.

The last year was exceptionally dry in Surigao, and the streams unusually low. Consequently water for hydraulicking was insufficient in quantity. An area of about two hectares was washed, but the cleanup had not been made at the time of this report.

How To Splice Wire Rope*

It is often the case where the wire rope is used that in case of a breakdown no man can be found on the job who can splice the severed ends, and naturally there is much time lost in securing some outside man to do the work. Splicing a rope is generally regarded as a mysterious process, whereas almost anyone can learn in a few hours how to do it. The accompanying illustrations show how a substantial wire-rope splice may be effected.

A hammer and a cold chisel for cutting off ends of strands, a steel fid or marlinspike for separating strands, two clamps for untwisting the rope, a sharp pocket knife for cutting the hemp core and a wooden mallet are all the tools needed. When starting to splice, proceed in this order:

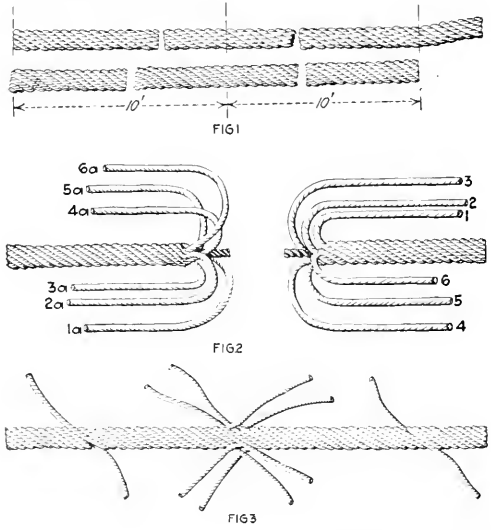
First, lay the rope on the ground, with ends overlapping 20 ft., 10 ft. each way from the center, as shown in Fig. 1.

Second, unlay the strands of both ends of the rope for a distance of 10 ft., as shown in Fig. 2. Cut off the hemp cores close up on both sides and bring the strands together so that the opposite strands will interlock regularly with each other.

Third, unlay strand 1*a* and follow up with strand 1 of the other end, laying it tightly in the open groove made by unwinding 1*a*; make the twist of the strand agree exactly with the twist of the open groove. Proceed with this until all but 6 in. of strand 1 is laid in or until 1*a* has become 20 ft. long, then cut off 1*a*, leaving an end about 6 in. long.

Fourth, unlay strand 4 of the opposite end and follow with strand 4*a*, laying it in the open groove as before, treating this as in the first case (see Fig. 3). Pursue the same course with 2*a* and 2, stopping 4 ft. short of the first set. Next do this with 5 and 5*a*, stopping as before, then with 3*a* and 3, and last with 6 and 6*a*. The strands are now all laid in with the ends 4 ft. apart, as shown in Fig. 4.

Fifth and last, the ends must be secured without enlarging the diameter of the rope. Take the two rope clamps, as shown in Fig. 6, and fasten them to the rope, as shown in Fig. 5. Twist them in opposite directions, thus opening the lay of the rope, as in Fig. 5. Next with a knife cut out the hemp core about 6 in. on each side. Straighten the ends and slip them into the place occupied by the core; then twist the clamps back, closing up the rope, and take out the slight inequality with the wooden mallet and a block of wood. Next shift the clamps and repeat the operation at the other five places, and the splice is made.



FIGS. 1 TO 6. THE SUCCESSIVE STEPS IN ROPE SPLICING AND THE CLAMPS EMPLOYED

*By C. J. Fuetter, Logan, W. Va., in "Coal Age," Nov. 20, 1915.

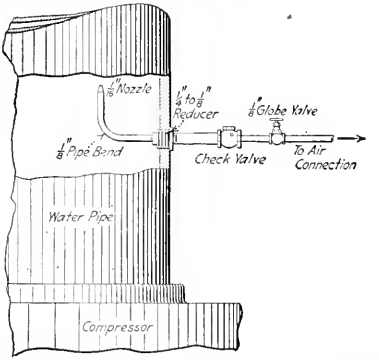
Salt Production of the United States in 1914 amounted to 34,804,683 bbl. of 280 lb. each, according to the Geological Survey. As a byproduct of the salt industry, there was 576,991 lb. of bromine made, and 19,403 tons of calcium chloride marketed in 1914. Michigan is the largest producer among the states, with 11,670,976 bbl. New York is second.

Details of Practical Mining

Circulating Cooling Water with Compressor Air

By Charles Labbe*

In the installation of a compressor in Nevada there was no running water available for cooling purposes. I therefore erected a thermo-siphon from a tank and used the same water at all times. However, as the water had to be hot to circulate well, it did not work efficiently. To remedy this I drilled a ¼-in. hole in the outlet pipe on top of the compressor and inserted a ¼- to ⅛-in. reducing bushing. A ⅛-in. pipe was swaged down so as to go freely through the opening, and a ⅛-in. thread was cut on the shoulder of this pipe, which was screwed into the bushing. The pipe was bent upward so as to permit the



ARRANGEMENT FOR CIRCULATING COOLING WATER

nozzle to deliver compressed air into the center of the water pipe. Connection was then made with the compressed-air line, the amount of air being regulated by a globe valve. A ⅛-in. check valve was also placed between the globe valve and the water pipe, so that no water would get in the air line if the compressor were shut down and the operator failed to close the globe valve.

Instead of pumping the water for cooling the compressor, just enough air is allowed to enter the water pipe to make the water circulate well, and I think it is cheaper than circulating the water mechanically and just as reliable. The hole in the nozzle being about $\frac{1}{16}$ in. and the air coming out with less than 5-lb. pressure, I regard this as an economical way of circulating the compressor-cooling water for a small installation. It also has the great advantage of simplicity.

*Nelson, Nev.

How to Designate Chains

Chains are designated by the diameter of the rod from which the links are made, as ½-in., 1-in., etc.; also by the form of the link, as close-link, in which one link is just large enough to inclose the two adjacent ones; open-link, in which the link is larger than in close-link; bar-chain, which consists of open links with a bar across the middle of each; twisted-link, in which each link is twisted through a certain angle, usually 90°; and straight- or flat-link, which is not so twisted.

Use of Cordeau-Bickford in Deep-Blast Firing

By L. B. Reifsneider*

The iron ore in the opencut workings of the Spanish-American Iron Co. at Daiquiri, Cuba, is cut into irregular blocks of varying dimensions by barren dikes. As it is desirable to work out the ore with as little sorting as possible, the spacing and depth of drill holes are largely governed by these dikes. The cut faces are from 25 to 50 ft. in height, but on account of the rock dikes, holes can rarely be drilled over 35 ft. in depth, about 28 ft. being the average.

The first trial of the Cordeau[1] was made in a series of eight flat lifting holes, varying in depth from 8 to 14 ft. in hard tough rock at the foot of a bench. The material is being handled by a steam shovel. The holes were charged as for ordinary battery firing and were connected in series. A 50-ft. lead of Cordeau was used and fired with a time fuse and a No. 8 blasting cap. The holes were charged with 40 and 60% Du Pont semi-gelatin. The results of the blast were excellent, but the finely broken condition of the rock indicated that, although the holes were not overcharged, at least 25% less explosive could have been used with satisfactory results had ordinary electric fuses been used as a detonating agent instead of the Cordeau.

A 30-ft. hole with very heavy burden was loaded in the same material a few days later. The toe had been well undercut by a previous blast, but would ordinarily have been charged with 250 lb. of R.R. powder. Remembering the experience with the former blast, in using Cordeau, it was decided to cut the charge 20%, or to 200

*Superintendent, Spanish-American Iron Co., Daiquiri, Oriente, Cuba.

[1]Cordeau-Bickford is a comparatively new detonating safety fuse. It consists of a flexible lead tube filled with tri-nitrotoluene as the detonating agent and is about the diameter of ordinary single-tape fuse. It is manufactured by the Ensign-Bickford Co., which has secured the patent rights from foreign manufacturers. Besides the economic advantages, the factor of safety in its use will recommend it to anyone using high explosives. The tri-nitrotoluene (usually abbreviated to t.n.t.), while in itself a powerful explosive, is insensitive to any ordinary shock; we have had a 10-ton locomotive run over a small test piece without exploding the Cordeau. It does not explode by friction and one can hardly ignite it with a match. Upon being exploded with a blasting cap its action is very rapid and powerful, the speed being estimated at about 17,000 ft. per sec. Wrapped and unwrapped Cordeau are manufactured. The unwrapped fuse is suitable for holes 50 ft. or less in depth, but for deeper holes the wrapped kind is recommended as the cotton sizing gives additional tensile strength. The weight of the lead tubing makes the unwrapped kind likely to tear when used in greater than 50-ft. lengths. The Cordeau is packed in convenient form, being wrapped on hardwood spools in such lengths as are most economical and convenient for the purchaser. In using the unwrapped Cordeau, care in handling is needed to prevent kinking and splitting the lead tube, but no more precautions are required than would be used in handling or loading with electric fuses. The Ensign-Bickford Co., Simsbury, Conn., publishes an interesting pamphlet on the use and properties of Cordeau.

lb. After blasting it was found that the holes were again overcharged, as the material had nearly all broken to hand-loading size and had been displaced so that a large portion of it fell on and obstructed the shovel loading track.

A combination of four lifters with a deep drill hole above was next tried. As the lifters were in very tough rock, they were loaded with 60% semi-gelatin, it being desired to get a shattering effect. The 30-ft. hole was in blocky material, and R.R. powder was used. The charge ordinarily used would have been 250 lb. of dynamite and 300 lb. of powder; this was reduced to 200 lb. of dynamite and 200 lb. of powder, and the results of the blast were excellent.

A number of holes had been drilled in ore in the toe of a cut face. As the holes were closely spaced it was desirable to fire them simultaneously. Cordeau was used and the charge cut from 200 lb. of 40% semi-gelatin to 125 lb. The blast was very effective, and the material was shattered so as to require very little blockholing afterward. Had 60% dynamite been available the economy would have been still more marked.

Cordeau was used in a five-hole deep blast in a cut floor. A charge of 250 lb. of black powder was calculated for each hole, as the burden was very heavy but badly broken-up ore, and the holes averaged 35 ft. in depth. Owing to caving, one of the middle holes in the heaviest burden admitted only 150 lb. of powder and another, 200. On firing, the holes which had admitted the whole charge broke well to bottom, but the other two were not strong enough to turn over their burden and the ore settled back in place very much cracked and shattered and but little more blasting was required to bring it down. Had blasting been with a battery and electric fuses, 300 lb. of powder per hole would have been the allowance, and under the conditions as they developed, the results would have been very unsatisfactory.

From these experiments the conclusion was reached that from 15 to 25% less explosive may be used in holes where Cordeau is used as a detonator.

The instantaneous explosion of the entire charge is obtained by using Cordeau, as it is the first thing put into the hole in starting to load and reaches to the bottom of the charge. As no blasting cap is necessary the danger of the tamping bar striking a cap in placing the explosive is obviated. The effect of the Cordeau is especially advantageous in using powder and gives the latter an effect similar to low-grade (15% to 25%) dynamite or Judson powder.

There is practically no danger of a missed hole going undetected in using Cordeau, as when the holes are exploded the Cordeau is entirely destroyed and a projecting piece of the Cordeau is very noticeable and means that the hole has not exploded. It can be connected up and fired with the ordinary cap and fuse at any time.

Its use is recommended for all deep holes and series blasting where electric firing methods can be used. The economy in its use in shallow holes is less marked, as its higher cost when used in blockholes, etc., more than offsets the saving that can be made in light charges.

As local prices for explosives are not applicable in the United States, no figures are given, but our records show actual average saving in explosives used, exclusive of the labor of charging, of 17.5% and in one case of 24%, as applied to deep blasts.

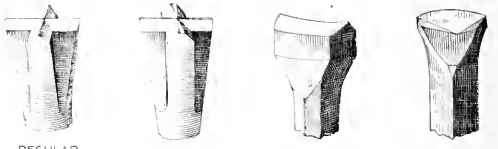
Some Comparative Tests of Piston-Drill Bits*

An investigation was made to compare the relative cutting speed and efficiency of some of the different types of rock-drill bits used in piston machines, including the regular cross bit, the low-center cross bit, a so-called flat cross bit, the Z-bit of the southeast Missouri type and the Joplin bull bit.

The drill steel used was 1¼-in. cruciform and 1-in. octagon Jessop drill steel, costing 14½c. per lb.—a better grade of steel than is commonly used in mining operations. These bits, except for one test, where they were forged by hand, were made and sharpened on a drill sharpener. Flat cross bits were made by filing the regular bit to the required shape. Dollies were made for forging these flat bits, but it was found difficult to form them on the sharpener, as it required the pounding down of too much metal in the center to bring out the flat edges.

A set of steel consisted of two "starters" about 27 in. long, a "second" 11 in. long and a "third" 60 in. long. "Starters" were made with a 2¼-in. gage, "seconds" with a 2-in. and "thirds" with a 1¾-in. gage.

The original purpose of the test was to compare the regular cross bit with a so-called flat bit made by flat-



TYPES OF BITS USED IN TEST

tening out the edges of the regular bit into the shape shown in the sketch. Earlier results seem to indicate that the flat bit possessed several advantages over the irregular, in that it appeared to cut faster, had greater endurance, lost gage less rapidly and, when used in rock of varying hardness, showed less tendency to run out of line.

Consideration of the results from starters was disregarded, as so many conditions enter in to make these results unreliable. A summary of results of these tests permits the following deductions to be drawn: Comparing the two "seconds," the regular bit seems to cut slightly faster, 3 in. per min. as compared to 2.93 in. for the flat. The flat "thirds" average 3.6 in. per min. as compared to 3.23 for the regular. From these results and from previous ones it is evident that a flattened bit will cut at least as fast as the regular sharp-edged bit. Comparing the average cutting speeds of the first two holes with the average of the entire run, it is seen that this holds true from the very start and does not take place as the bit wears down.

The reason for making a bit of the flat shape in the beginning was because of the observation that the irregular bit became flattened on the edges, with corners rounded and centers high, after being used in one or two holes. It was thought, therefore, that by putting more metal at the outside, the corners would hold up

*Abstract of paper by Prof. C. L. Forbes and L. M. Cummings, in "Bulletin of Bureau of Mines and Metallurgy," University of Missouri, August, 1915.

better, and such was found to be the case. It was especially noticeable that the center did not wear high in the better flat bit and the rounded corners were much sharper than with the regular bit.

From these tests the theory of chipping or penetration as applied to rock drilling appears not to hold, at least under the conditions in this work. Screen analysis of cuttings were made, in order to find the difference in coarseness with different bits. The results, however, were not satisfactory, as so many conditions entered to influence the fineness of cutting.

These tests were discontinued without running the drill steels to their limit, and in most cases it would have been possible to drill at least 10 ft. with every steel, except with the "starters." Under usual mining conditions in rock as hard as the granite used in these tests, steels would not be used more than twice, and in most cases not more than once. It would seem that economy could be attained by using the steel longer, as a difference in cutting speeds between the sharp and dull bits is almost negligible, while the slight advantage gained by using sharp steel is more than offset by the increased expense of sharpening the steel and transporting it to and from the working face. It is not meant that miners should be made to use dull steel or poor steel, but it is believed that one set of properly tempered steel could be used efficiently in at least five holes in rock similar to the granite used, and that no greater drilling speed would be obtained by using a new set of steel in each hole.

The loss of gage in drilling the first hole in these tests was usually $\frac{1}{4}$ in., and was as much as the total loss in drilling the four succeeding holes. A 2-in. bit, for example, would be reduced to $1\frac{3}{4}$ in. after drilling one hole, but it would lose only $\frac{1}{4}$ in. in drilling four more holes.

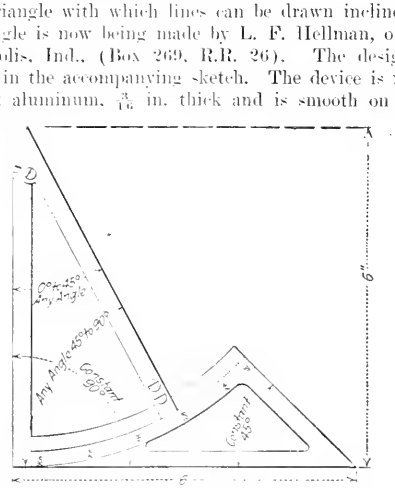
Summing up the comparison of flat and regular cross bits with piston drills in granite, the following deductions may be made: (1) A flat bit with cutting edges about $\frac{3}{32}$ in. wide will cut as fast from the beginning as the regular sharp-edged cross bit, proving conclusively that the so-called chipping action that is supposed to take place in rock drilling is practically negligible. It is difficult to conceive of a flat surface breaking away rock in any manner except by impact or crushing, and the fact that a new sharp flat bit cuts as fast as the new regular sharp-edged bit is conclusive proof that little or no chipping takes place under the condition of these experiments. (2) The flat bit is more difficult to forge in the sharpener than the regular bit, but by hand, if proper dollies are provided, it may be forged just as easily. The low-center cross bit, some tests of which were made, seems to be quite similar to the flat bit, and it is thought that the advantage of the low-center bit is due to its wearing down to practically the shape of the flat bit, and that instead of forging a flat bit, it might be just as well as to forge a low-center bit, which is more easily made. (3) The relative speed of flat bits, as compared to regulars, is greater with the smaller gages, often as much as 25%.

Relative to the comparison of regular, Z- and bull-bits, the following deductions were made: (1) The low-center cross bit is superior in cutting speed and endurance to the regular cross bit. (2) The Z-bit cuts faster than any of the other bits under the conditions in these tests. (3) The bull-bit has the one advantage of losing gage less rapidly than the others, but its cutting speed is much less.

These conclusions apply only to the use of bits for piston drills in granite. The cutting action of hammer-drill bits may be considerably different.

Universal-Angle Drafting Triangle

A triangle with which lines can be drawn inclined at any angle is now being made by L. F. Hellman, of Indianapolis, Ind., (Box 269, R.R. 26). The design is shown in the accompanying sketch. The device is made of cast aluminum, $\frac{3}{16}$ in. thick and is smooth on both



HELLMAN'S UNIVERSAL TRIANGLE

sides. The base and one side are rigid, but a part of the hypotenuse swings about a friction point. The arc is graduated to half-degrees, but quarter-degrees can be estimated. Triangles graduated for slope and pitch are also supplied. Only the 6-in. size is made, and this sells for $2.

Draining Ground Prior to Shaft Sinking

In ordinary shaft sinking the water encountered is pumped out as the deepening of the shaft progresses. On a lease of the Mary Calf land in northeastern Oklahoma two large shafts that were being sunk were made dry during sinking operations by the use of extraneous air lifts.

Drill holes lined with 5-in. casing and reaching to a depth of 170 ft., to which depth the shafts will go to reach the bottom of the ore formation, are put down by the use of churn drills. After the holes are drilled and cased, a $\frac{3}{4}$-in. air line is placed in each casing, forming an air lift, and when the pressure of air is turned on a heavy volume of water is lifted. From three holes at one shaft the combined water forced out by the air pressure was 800 gal. per min., which was sufficient to keep the shaft well drained and dry.

Cleaning of Manways

Timbers in all manways in daily use should be cleaned of all loose rock lodged upon them at least once in every 24 hours. Manways in daily use should be kept clear of obstructions.

Details of Milling and Smelting

Use of Cement Instead of Lead for Pipe Joints

The use of portland cement for making the joints of cast-iron water mains has become common in southern California cities. The practice appears to have originated in the water department of Longbeach, Calif., about ten years ago, and the success there obtained has caused a number of other cities to adopt the same plan, says *Engineering News*, Nov. 25, 1915. The superintendent of the Longbeach water-works, Clark Shaw, declares that the cement joint is not merely cheaper than the ordinary lead joint, but is tighter and more permanent.

The method of making the joint is as follows: After the pipes are connected, a ring of dry jute is inserted in the bottom of the bell and the bell filled with neat-cement paste. It is essential that this paste be mixed with only enough water to moisten it, but not enough to make it soft. After the bell is filled with the paste it is packed with a long calking tool, like that used for calking a lead joint. If the paste is of the right consistency it should pack under the tool until it is almost as hard as lead.

After the first calking, the joint is refilled with paste, which is again packed solid with the calking iron; this is repeated a third time. The joint is then neatly rounded off with a collar of 1 : 1 cement and sand. The cement is allowed to set for 48 hr. before water pressure is turned on the pipe. In case of necessity, however, water may be turned into the pipe within 24 hr. The only lead joints now used in Longbeach are in pipe that has to be put in service as soon as it is laid. The pipe used has the standard hub and spigot. A line of pipe 6,400 ft. long was recently laid with cement joints, and not a single leak was found when it was tested.

When it is necessary to take up pipe laid with the cement joint, a section of the cement on top, about 60° wide, is chipped out to the bottom of the bell, and the joint is then readily broken. This work is much more easily done than unjointing pipe having lead joints.

An important advantage of the cement-jointed pipe is that the conductivity of the line for electric currents is much reduced, as there is cement insulation at every joint. Liability of damage to the line by electrolysis is greatly reduced, although if one joint or only a few were made with cement there might be corrosion at these points.

A comparison of costs of the material required for a 4-in. pipe joint shows that with lead at 5½c. per lb. the material for a lead joint cost 29c. and the material for a cement joint, 3½c. At the present high prices of lead the difference is much greater, and on larger sizes of pipe the large saving possible makes the change one which is well worth the attention of water-works engineers. There is also much less expense for labor in the cement joint than for the lead joint, and the work is simpler. This should be a valuable idea in isolated districts such as mining camps.

Commenting editorially on the foregoing the *News* further says:

Why should the cement joint be absolutely water-tight against an internal pressure of 100 lb. per sq.in. or more, while the cement joint for sewer pipes in practically universal use be exceedingly apt to leak under the ordinary pressure of ground water?

The answer to this question is probably to be sought in the manner in which the cement joint for water mains is made up—with a cement paste containing barely enough water to moisten it, packed into the pipe bell with a calking tool and hammered home as if it were lead.

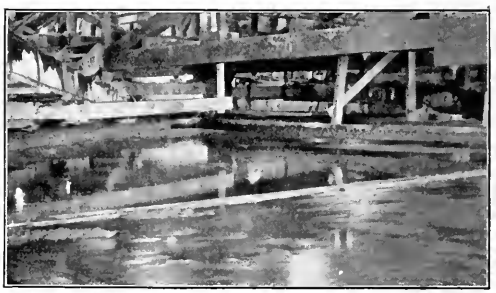
It is common knowledge that the strength of a cement briquette is greatly affected by the packing of the cement in the briquette mold; but we recall no tests made to determine how strong a briquette could be produced by compressing a very dry paste under repeated hammer blows. The long experience with the cement water-pipe joint now available indicates that such cement is not only very strong, but about as impermeable as metal.

*

Foam Sweep for Thickeners

By D. W. Minier*

The device here described for preventing foam accumulation on the surface of Dorr thickeners seems to be well known to some and not to others. It is said to have originated in Tonopah practice and is here described as used in an Arizona mill. It works well with continuous



FOAM SWEEP ON A THICKENER

counter-current decantation where an air lift is used for the transfer of the overflow solution of one thickener to the next in series.

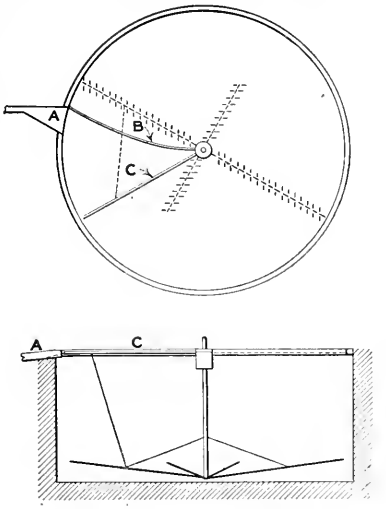
The idea is simply that of a fixed curved baffle extending from the periphery to the mixing cylinder at the center of the thickener, and a rotating float that pushes the foam ahead of it and, in passing under the curved baffle, forms a gradually closing V that forces the foam to an outlet launder bridging through the annular launder.

The curved baffle is of 1x3-in. stuff, and its flexion is held by a wire chord. It is suspended from the bottom member of the overhead truss by 2x4-in. pieces and fastened by lagscrews through slots in the 2x4-in. pieces, so that its elevation can be adjusted. There is a strip of belting fastened along its lower edge to form a flexible contact with the rotating float.

*Mining engineer, Pearce, Ariz.

The rotating float is of 4x4-in. seasoned redwood, painted with P. & B. paint. At the center of the tank it is fastened loosely to the mixing cylinder or shaft by an iron hoop, and rotation is effected by a rod fastened through the float and hooked over the tension rod of one of the rabble arms.

The overflow foam launder is 3 ft. wide and 4 in. deep and bridges over and through the overflow launder, its floor being 2 in. higher than the solution outflow holes in the annular launder. The level of solution in the thickeners should be maintained just slightly above the floor line of the foam-outflow launder, so that a thin sheet of solution



SHOWING THE FOAM SWEEP

is flowing out. A spray pipe above this launder helps to break up the foam and assist its flow. The solution level in the thickener can be regulated by plugging some of the holes in the annular launder, but is better done by means of sheet-iron gates across the launder, sliding in grooves on each side of solution-discharge outlet.

The sweep can of course be used only where there is a suitable place to send the foam and a small amount of the solution. In the plant mentioned, the thickener preceding the agitators is so equipped and the foam is sent to the first agitator of the series.

As the thickeners following the agitators are run on the counter-current system with air-lifts for transfer of solution, the foam from the first thickener is sent to the air-lift well for overflow solution of the second thickener and is thus returned with the diluent to the thickener of its origin. The air lift is effective in breaking up the foam.

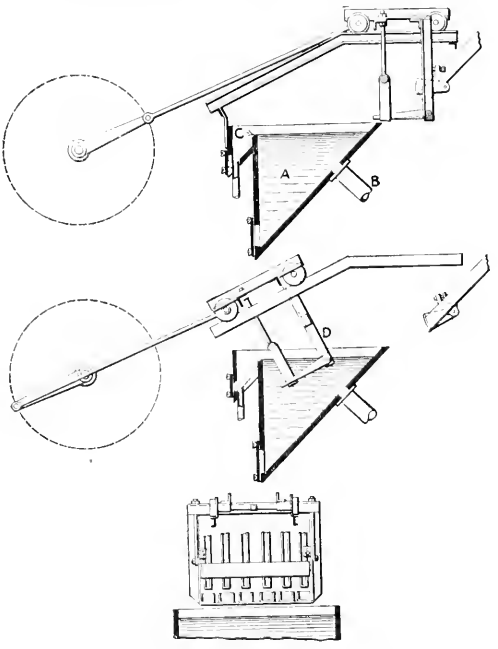
Electromagnetic Treatment of Monazite Sand

In Technical Paper 110 of the Bureau of Mines, by Karl L. Kithil, are given the following suggestions on the electromagnetic separation of monazite sand:

In concentrating monazite sand by the electromagnetic process, it is essential that great care be taken throughout the entire operation that the strength of the current is the same at all times, as the slightest variation will cause imperfect separation. An impure product and much loss of monazite will result unless the precaution is observed, as the monazite will be taken up by the wrong pole. If the strength of current be too great some of the monazite will be mixed with the valueless ilmenite or garnet, or if the amperage be too low, ilmenite or garnet will be carried over to the next following poles and will then become mixed with the monazite, and at the same time too many of the finer sizes of monazite will escape in the tailings. The distance between pole magnets must be carefully adjusted and the amperage of each magnet regulated by rheostats.

Stone's Flotation Apparatus

George C. Stone, of New York, has patented (U. S. Pat. 1,156,041, assigned to the New Jersey Zinc Co.) a flotation apparatus providing for the introduction of ore into the flotation liquid intermittently, preferably in relatively small individual charges and with a negligible amount of agitation of the liquid. For this purpose a carrier is provided for immersing the ore in the flotation liquid, as shown in the accompanying illustration. *A* is the flotation liquid, *B* the supply pipe there-



FLOTATION APPARATUS WITH IMMERSING FEEDER

for, *C* the barrier over which the mineral particles are floated, and *D* is the carrier for immersing the charge in the flotation liquid.

The carrier consists of a series of individual trough-like pans, movable in unison, entering and leaving the flotation liquid in a substantially rectilinear path and at an acute angle to the surface. When the ore carrier moves upward and out of the flotation liquid, it may be brought into coaction with a suitable source of ore supply and receive a new charge preparatory to the downward movement into the flotation liquid.

The Assayer and Chemist

Analysis of Commercial Selenium

By H. D. Greenwood*

Within the last two years a demand has been created for selenium and its soda salt, the glass industry using it to make ruby glass and the dyestuff industry to replace the sulphur derivatives. The following method for the analysis of commercial selenium has been in use in this laboratory for the last five years, and its accuracy has been demonstrated by checked assays with chemists here and abroad. It is so simple, quick and accurate that it has been placed among the routine methods. No originality is claimed.

Selenium Determination

Weigh out ½-gram (0.5000-gram) portions of the finely ground sample (100-mesh) into a 150-c.c. beaker. Add 10 c.c. H_2O, then add slowly 15 c.c. conc. HNO_3 and cover with a watch glass. Evaporate to dryness on the water bath, take up with 10 c.c. HCl (1:1) and 20 c.c. H_2O. Filter off the insoluble into a 400-c.c. beaker, and to the filtrate add sufficient conc. HCl to make a solution of 70% conc. HCl.

The selenium is precipitated at room temperature by a slow current of SO_2 at the rate of two small bubbles a second. Care must be taken to keep the solution at room temperature (60-70° F.) by placing the beaker in a vessel of running tap water.

When all the selenium has been precipitated and the solution smells strongly of SO_2, remove and allow to settle for one-half hour. Decant the supernatant liquor onto a tared gooch and wash the precipitated selenium in the beaker three times with conc. HCl and once with cold water, decanting each time.

To the precipitate still in the beaker add 25 c.c. cold water, and from a wash bottle with ordinary stream, hot water with vigorous stirring until the selenium turns black and granular. This is readily filtered off, washed with hot water and dried at 110-115° C. to constant weight. Weigh as metallic selenium.

Tellurium Precipitation

The filtrate from the selenium is diluted to four times the bulk with hot H_2O; 25 c.c. NH_4OH and 3 grams of powdered tartaric acid added, saturate the liquid with SO_2 (takes about two minutes) and bring to a boil. Allow to stand for two hours or longer on a hot plate. The granular precipitate is filtered on a tared gooch, washed with hot water, dried at 115° C., to constant weight and weighed as metallic tellurium.

The foregoing method, when strictly followed out, gives accurate results, but the beginner is apt to deviate from the method and lead to the following inaccuracies: If the temperature of the solution when precipitating Se is above 70° F., the Se balls up occluding impurities which can never be washed out; if below 60° F., incomplete precipitation occurs. If the precipitated Se is not made granular as stated, it cakes in drying and holds moisture even at 110° C. He also errs in not testing wash waters and filtrates, and finally in not having beakers and precipitating tubes entirely free from grease; the latter in this laboratory are always flame-burned before using.

*Chief chemist, U. S. Metals Refining Co., Chrome, N. J.

Recovery of Molybdenum from Laboratory Waste

In a recent paper in the *Analyst*, J. A. Prescott suggests a method for the recovery of ammonium molybdate used in phosphate determinations. The method is based upon the fact that if ammonium molybdate is boiled with an excess of acid, molybdic acid is precipitated. All residues, including acid liquors from which the yellow phosphomolybdate precipitate has been removed or alkaline or neutral liquors obtained by dissolving the yellow precipitate in alkali or ammonia and ignited residues, are thrown into a large evaporating dish, which is kept heated in order to concentrate the liquors.

As the liquors are concentrated, molybdic acid is precipitated, and eventually, as there is a preponderance of acid residues, a strong, acid, sirupy liquid is obtained, from which crystals of ammonium sulphate or ammonium nitrate separate on cooling. A certain proportion of phosphomolybdate separates out with the molybdic acid. The whole is filtered, and the yellow molybdic acid is washed with cold water and dissolved in excess of ammonia. To the ammonia solution, magnesia mixture in carefully added until no more phosphate precipitates. The solution is filtered, concentrated to a small bulk (keeping ammonia present in excess) and allowed to crystallize.

The mother liquors are worked up for further quantities of molybdate, and if necessary, the crystals obtained are recrystallized. When a blue color, due to the presence of lower oxides of molybdenum, is produced through allowing the waste liquors to evaporate to dryness and overheating, it may be removed by the addition of hydrogen peroxide.

Filtering Aluminum Hydroxide

A description of certain details of manipulation are given by H. W. Daudt, in the *Journal of Industrial and Engineering Chemistry*, October, 1915, by which he says it is possible to filter and wash aluminum-hydroxide precipitates readily.

The solution of the aluminum salts containing only a small excess of acid is heated until steam is given off copiously, while stirred constantly. Freshly distilled ammonia is carefully added until its odor can be detected in the steam. The solution with suspended precipitates is then boiled for approximately three-quarters of a minute—not more than a minute. The solution is immediately transferred to a prepared filter paper, no attempt

being made to decant from the supernatant liquid. The precipitate remaining on the sides of the beaker is transferred as rapidly as possible by means of boiling hot water and then washed with hot water or with an ammonium-chloride solution of definite concentration.

He has carefully checked the statement of Hillebrand, that complete removal of ammonium chloride from aluminum hydroxide before ignition is unnecessary. Consequently it is possible to use ammonium-chloride solution for wash water without sacrifice of accuracy by volatilization of aluminum or ferric chloride; while it is of advantage to have small quantities of ammonium chloride present, because the hydroxide precipitates tend to become colloidal when electrolytes are altogether absent in the wash solution.

What Is a Normal Solution?

What is a normal solution? The definition is not reassuring: "A normal solution is one in which a liter of solution contains a quantity of the substance, expressed in grams, equal to its molecular weight, divided by its hydrogen equivalent." Fortunately, this definition is not so bad as it looks, says *Power*, Sept. 28, 1915.

For instance, a normal solution of hydrochloric acid ($H + Cl = 1 + 35.4 = 36.4$ molecular weight) would contain 36.4 grams of hydrochloric acid per liter. But normal sulphuric-acid solution ($H_2 + S + O_4 = 2 + 32 + 64 = 98$ molecular weight) would contain 49 grams per liter, since its hydrogen equivalent is two. Normal sodium chloride ($Na + Cl = 23 + 35.4 = 58.4$) would contain 58.4 grams of salt per liter, but normal sodium-carbonate solution ($Na_2CO_3 \cdot 10\ H_2O = 23 \times 2 + 12 + 16 \times 3 + 10 \times 1 \times 2 + 10 \times 16 = 286$) would contain 143 grams per liter, since the two sodium atoms have a hydrogen equivalent of two.

This last compound shows that in making up normal solutions the water of crystallization must be considered. Although we usually write sodium carbonate as Na_2CO_3 in chemical equations, it is done only for convenience, and when normal solutions are prepared it is necessary to recognize that the salt as ordinarily prepared is not Na_2CO_3 of 106 molecular weight, but $Na_2CO_3 \cdot 10\ H_2O$ of 286 molecular weight.

The normal solutions are sometimes inconvenient to prepare. For instance, a normal solution of hydrochloric acid or of ammonia would be so strong as to lose HCl or NH_3 by evaporation, while normal solutions of some salts would often be impossible because saturation is reached below the normal point. For this reason tenth-normal solutions are often used $\left(\text{usually written } \frac{N}{10}\right)$ which are one-tenth the concentration of the normal solution.

AMOUNT OF SUBSTANCE IN NORMAL SOLUTIONS

Substance	Chemical Formula	Molecular Weight	Hydrogen Equivalent	Amount in Grams Per Liter
Sodium carbonate	$Na_2CO_3\ 10\ H_2O$	286 16	2	143 03
Sodium carbonate	Na_2CO_3 (fused)	106 00	2	53 00
Sodium bicarbonate	$HNaCO_3$	84 01	1	84 01
Potassium carbonate	K_2CO_3	138 20	2	69 10
Sodium chloride (salt)	NaCl	58 46	1	58 46
Ammonia	NH_3	17 03	1	17 03
Sulphuric acid	H_2SO_4	98 09	2	49 05
Hydrochloric acid	HCl	36 47	1	36 47
Caustic soda	NaOH	40 01	1	40 01
Caustic potash	KOH	56 11	1	56 11
Calcium chloride	$CaCl_2$	110 99	2	55 49
Calcium hydroxide	$Ca(OH)_2$	74 02	2	37 01

With the foregoing explanation in mind, the calculation of normal solutions becomes an easy matter. From the formula of the substance (including water of crystallization) and the table of atomic weights in any chemistry, calculate the molecular weight of the substance, divide by its hydrogen equivalent and the result is the number of grams of the substance which (assuming it is chemically pure) would give a normal solution when dissolved in a liter of water.

The accompanying table gives the amount required in a normal solution of a number of substances in common industrial use. The molecular weights are calculated by the accurate values given in the International atomic-weight table, 1914.

Toughening Filter Paper

A paper in the *Chemical News*, by Dr. Clayton Beadle, on the toughening of filter papers, describes a useful and simple method of strengthening a filter paper to such an extent that it will withstand the pressure produced by a powerful filter pump.

The paper is folded and fitted into a dry funnel in the ordinary way, and then a few drops of nitric acid of sp.gr. 1.42 are allowed to fall in the apex of the paper cone. The funnel is canted and quickly rotated so as to saturate the free unsupported apex of the cone with the acid, and is then immediately rinsed out under a tap, being filled and emptied from the top repeatedly, and finally rinsed out with distilled water if the presence of tap water is undesirable.

This treatment does not slow the filtering action of the paper; on the contrary, it tends to accelerate it, though treating the paper similarly all over slows the filtering very considerably—four or five times. The method is credited to E. J. Bevan, about 30 years ago, but few people seem to know of it.

The Determination of Lead in Blast Furnace Slags

By James O. Johnstone*

Weigh 2 grams of the finely pulverized chilled slag into a 400-c.c. beaker. Add 150 c.c. boiling water and 25 c.c. dilute sulphuric acid (1:1) and stir until all the slag is decomposed; some sulphides and carbon will remain undissolved. Then add an excess of potassium permanganate (about 2 grams) and boil for 3 min. Remove from the hot plate and add 5 grams tartaric acid and continue boiling till all the manganese dioxide is in solution. Filter off the lead sulphate, wash well, transfer paper and precipitate back into the beaker, digest with ammonium acetate, and titrate with ammonium molybdate. Time required: 20 min.

To Bore Holes in Rubber Corks

By Arthur S. Levy†

I have just come across the note on boring holes in rubber corks on page 440 of the *Journal* of Sept. 11. The way described is good, but a much kinkier kink is to use methylated spirits (any form of alcohol will do) to wet the cork-borer, only a few drops being required. The borer bites much better.

*Chemist, International Lead Refining Co., East Chicago, Ind.

Correspondence and Discussion

Fineness of Ore Crushing for Assaying

If Mr. Dewey's request for practical data relating to the decomposition of $NaHCO_3$ (*Eng. and Min. Journ.*, Nov. 20, 1915, p. 851) means an analysis of evolved gases at various temperatures up to the melting point of an assay charge, I must confess that such information is not available. But the following—call it fact or theory, as you please—should serve to substantiate the correctness of my contentions.

Sodium bicarbonate ($NaHCO_3$) decomposes slightly at ordinary temperatures. It will decompose completely below 200° C. The constituents of a charge do not react till the slag-formation temperature is reached; in other words, below fusion—usually above 500° C.

Sodium bicarbonate cannot be melted; it dissociates. The dissociation of sodium bicarbonate takes up heat, and we can no more expect fusion before the $NaHCO_3$ is converted to Na_2CO_3 than we can hope for the roasting of wet concentrates before the water is expelled.

The observable differences in fusing charges containing equivalent amounts of Na_2O as $NaHCO_3$ and Na_2CO_3 are: The bicarbonate charge dusts more—the CO_2 of Na_2CO_3 is not appreciably given off till displaced or fusion begins and the charge is no longer dry—fusion takes 5 to 20% longer, depending on charge and temperature, and the point of maximum reactions is reached earlier with the normal carbonate charge. This is simply in accord with the known properties of the two salts. To argue that fusion takes place around the sides of the crucible before the center of charge has reached a temperature sufficient to decompose $NaHCO_3$, while possibly true in certain cases, is begging the issue. Progressive assayers are substituting Na_2CO_3 for $NaHCO_3$ without any detriment to their results.

E. J. Hall.

New York, Dec. 7, 1915.

On Zinc Poisoning

The editorial note as to "Zinc Poisoning" in the *Journal* of Aug. 14, was read by me with much interest. The malaise known as "spelter shakes" is familiar to anyone connected with the melting of brass, but quite unknown in zinc-retort plants. When I was in Iola I never had any, although I was active around the spelter furnaces and inhaled considerable oxide of zinc from furnaces working on ores high in iron. In my work at Hartford on electric zinc smelting, I had "the chills" many times, but only so far as I remember when working on changing an electrode or under other conditions where the vapor burnt was rich metallic vapor as distinguished from a vapor with a quantity of indifferent gas mixed with it.

"The chills," or "the shakes," have peculiar characteristics. Usually they come on quite suddenly from 10 to 16 hr. after exposure. Soreness in the limbs, then a feeling of chilliness, pronounced restlessness and finally copious perspiration with deep breathing are manifest. I finally made it a practice to get up out of bed when I felt first a chill, heat some water and drink it after going through some calisthenics. This seemed to increase the sweating. Next morning I felt particularly fine.

Milk, if taken before or after exposure to the fumes, seemed to help. At least all my force got into the habit of taking milk when running the furnace.

There is no doubt that some form of flocculent albumen is an antidote for any mineral poison, and zinc under some conditions should be regarded as one in a mild form. However, possibly the hypothesis offered by the engineers of the New Jersey Zinc Co. that traces of copper in the zinc would give "spelter shakes" may be the true explanation. At all events, it is a fact that under certain circumstances zinc will poison people slightly, although in any event the period of intense physiological activity induced is enough to clear the system of poison completely. The general health of brass melters is known to be good, and Percy, in his "General Metallurgy" testifies to the fact that an old workman, who had lived and breathed zinc oxide for fifty-odd years, remained happy, cheerful and well.

Woolsey McA. Johnson.

Hartford, Conn., Nov. 17, 1915.

Society Employment Bureau

Referring to the last paragraph of the letter of Ernest McCullough in the *Journal* of Nov. 20, page 851, the following is quoted:

> . . . out of the hands of employment agencies, which bleed unfortunate technical men that have no other means of securing positions.

The few employment agencies that handle technical mining men are run along lines that make any such slur as the foregoing entirely uncalled for. The business of bringing the employer and the technical man together is as clean and legitimate and serves as much of a need, perhaps, as the trade journal, which depends for its business life on the bringing together of the machinery manufacturer and the mine manager through the medium of advertising.

Mines Technical Agency,
N. H. Beaton, Manager.

Los Angeles, Nov. 26, 1915.

Peculiar Magnetic Phenomenon

The "Peculiar Magnetic Phenomenon" described by Mr. Chase in the *Journal* of Dec. 4 may possibly be due to the track rails having once been handled with an electromagnet and becoming permanently magnetized.

In steel mills, nowadays, a great deal of the material is lifted and loaded by means of powerful electromagnets suspended from overhead cranes. I have heard of carloads of material that could be unloaded at destination only with great difficulty, because so many of the pieces were magnetized that all tended to cling together.

George W. Riter.

Salt Lake City, Utah, Dec. 7, 1915.

New Zealand Department of Mines, Wellington.

MINERAL PRODUCTION OF CALIFORNIA FOR 1914, With Mining Law Appendix. Pp. 184, illus. Bull. 70, California State Mining Bureau, San Francisco.

This bulletin, which is published for free distribution, gives the usual statistics of mineral production and notes of mining developments. The total value of the minerals produced was $93,314,760. This is somewhat less than the figure originally given by the bureau, which is accounted for by the fact that it estimated the gold, silver and platinum production, in order not to delay the issuance of the bulletin. The revised figures of the United States Geological Survey were received before the bulletin was printed, and the corrections are given in a supplement to the chapter on metals.

There were 42 mineral substances produced, and of the 58 counties in the state, 56 of them produced mineral of some kind. Petroleum, of which 102,881,907 bbl. were produced, was highest in value in 1914, as it has been for several years. Gold was next in value, with 999,113 oz., valued at $20,653,496. The copper output was 30,491,135 lb., valued at $4,055,375. There was a decrease of more than $5,000,000 in the total value of all minerals produced in 1914, as compared with 1913. Petroleum, however, increased 387,375 bbl., but decreased in total value $1,090905, owing to a reduction in price in five of the seven fields. In the production of metals there was a total decrease in 1914 from the previous year, of $1,087,986, covering nine different metals. Of these metals only three—gold, iron and lead—showed an increase. In the past fifteen months there has been an increase in copper production and also in quicksilver, due of course to the war in Europe. There has also been some increase in zinc production in the past year. No production of antimony has been recorded since 1901, when there was an output of 50 tons. There has been a large amount of prospecting and development in the past twelve months, and it is expected that 1915 will show a record of renewed production. There has been an increased demand for magnesite, and production in 1914 exceeded that of 1913 by 1,806 tons; it was valued at $10 per ton, as compared with $7 per ton last year. The production of chrome showed a small increase, but for some unaccountable reason the total value decreased from $12,700 in 1913 to $9,434 in 1914.

PRACTICAL MINING ON THE RAND. By E. M. Weston. 5x7½; pp. 55; illus. Published by the author at Johannesburg, South Africa.

There have been many books published for the mining engineer or mining operator, but few, if any, published specifically for the shift bosses and the miners themselves—certainly none more interesting than the little booklet by E. M. Weston, entitled "Practical Mining on the Rand." In the preface Mr. Weston says: "Some little time ago I set out to lecture to miners on their work. I soon found that if I wished to retain their interest and to really help them, I would have to leave out very much that is usually included in a course of mining lectures and would have to bring in many things that are to be found in no book today." The booklet contains his lectures to his miners very much as he gave them. They are practical talks on practical matters to practical men.

The first lecture deals with "Handling Rock Drills Underground" and takes up in detail the method of rigging up the drill, the points to be avoided and the points to be taken advantage of in order to get the greatest results with the greatest ease to the miner. It deals with the causes of drills sticking in the holes; it takes up in detail the operations of running a drill, from the standpoint of the drill itself, as well as the round which is being drilled; it goes into considerable detail about the operations involved in changing steels, etc.

Another chapter, entitled "Explosives and Their Use," defines for the miner the various brands and kinds of dynamite and explains their differences and their uses. The question of fuse and tamping is also discussed at length. The layout of holes to break the ground to best advantage is discussed, and diagrams are shown of the different schemes of drilling.

Under the heading, "Developments," he goes into this question of layout of holes and drilling of rounds in very much greater detail and summarizes in the most understandable way the principles that must be considered in order to get the best results in drilling and breaking the breast of a drift.

Under the title, "Stoping," is a very interesting chapter on the setting up of the drill, drilling and the breaking of a round in stopes, and under the heading, "Hand Hammer Work," the subject of hand drilling is gone into at some length.

The pamphlet comprises 55 pages and can be read with profit not only by the shift bosses and miners for whom it was intended, but by the mine superintendent and the engineer.

NEW PATENTS

United States patent specifications listed below may be obtained from "The Engineering and Mining Journal" at 25c. each. British patents are supplied at 40c. each.

ALUMINA—Method for Producing Pure Alumina from Clay and Other Alumina-Bearing Materials. Max Buchner, Heidelberg, Germany. (U. S. No. 1,162,130; Nov. 30, 1915.)

BAG-SHAKING APPARATUS. Albert D. Bryant, Palmerton, Penn., assignor to New Jersey Zinc Co., New York, N. Y. (U. S. No. 1,163,318; Dec. 7, 1915.)

CONCENTRATION—Chat Separator for Concentrating Jigs. Alvin P. Standefer, Miami, Okla. (U. S. No. 1,162,112; Nov. 30, 1915.)

CONCENTRATOR. Albert J. Matter, Portland, Ore. (U. S. No. 1,161,945; Nov. 30, 1915.)

CONCENTRATOR. John F. Isbell, Los Angeles, Calif., assignor to Orren Allen, Denver, Colo. (U. S. No. 1,163,344; Dec. 7, 1915.)

CRUSHER ROLL. Bruce W. Traylor, Allentown, Penn., assignor to Traylor Engineering and Manufacturing Co., Allentown, Penn. (U. S. No. 1,162,892; Dec. 7, 1915.)

CRUSHING—Apparatus for Disintegrating Ore and Other Material. Harry W. Hardinge, New York, N. Y., assignor to Hardinge Conical Mill Co., New York, N. Y. (U. S. No. 1,161,859; Nov. 30, 1915.)

DRILL—Rock Drill. Warren Wood, Paterson, N. J. (U. S. No. 1,162,964; Dec. 7, 1915.)

DRILL—Rock Drill. Vincent John O'Brien, Denver, Colo. (U. S. No. 1,162,249; Nov. 30, 1915.)

FLUE DUST—Process of Agglomerating Flue Dust or Other Finely Divided Material. Carl Giesecke, Brunswick, Germany. (U. S. No. 1,162,600; Nov. 30, 1915.)

FURNACE—Metallurgical Furnace. Franz Meyer, Uerdingen, Germany, assignor to Dwight & Lloyd Metallurgical Co., New York, N. Y. (U. S. No. 1,162,634; Nov. 30, 1915.)

FURNACE—Metallurgical Furnace. Utley Wedge, Ardmore, Penn. (U. S. Nos. 1,162,532 and 1,162,533; Nov. 30, 1915.)

HOISTING—Safety Stop Mechanism. Alexander J. Nicht, Chicago, Ill., assignor, by mesne assignments, to Allis-Chalmers Manufacturing Co. (U. S. No. 1,163,029; Dec. 7, 1915.)

LAMP—Miner's Lamp. Augie L. Hansen, Chicago, Ill., assignor to Justrite Manufacturing Co., Chicago, Ill. (U. S. No. 1,162,915; Dec. 7, 1915.)

LEACHING—Process for Extracting Valuable Copper Constituents from Cupriferous Ores and Their Gangues. Eugene Erdös, Kolozsvár, Austria-Hungary, assignor to Azurit Co., Ltd., for Chemical Industry Kolozsvár, Kolozsvár, Austria-Hungary. (U. S. No. 1,162,044; Nov. 30, 1915.)

ORE-PULP—Apparatus for Treating Ore Pulp. Bernard MacDonald, South Pasadena, Calif. (U. S. No. 1,163,097; Dec. 7, 1915.)

POTASSIUM AND SODIUM SALTS FROM KELP-ASHES. Process for the Manufacture of. Carl Klingbiel, Biebrich, Germany. (U. S. No. 1,162,617; Nov. 30, 1915.)

SLAG—Art of Converting Molten Slag into a Highly-Porous Mass. Carl H. Schol, Allendorf, Germany. (U. S. No. 1,163,605; Dec. 7, 1915.)

SMELTING—Apparatus for Continuous Smelting of Sulphide Ores. Gustaf Haglund and Anton Grönningsæter, Christiansand, Norway. (U. S. No. 1,163,234; Dec. 7, 1915.)

TUNNELING MACHINE. Samuel Hoar, Virginia, Minn. (U. S. No. 1,162,607; Nov. 30, 1915.)

WELDING—Method of Welding. Edwin E. Slick, Johnstown, Penn., assignor of one-half to Luther L. Knox, Avalon, Penn. (U. S. No. 1,161,419; Nov. 23, 1915.)

ZINC—Removing Cadmium from Zinc Ore. Gilbert Rigg, Palmerton, Penn., assignor to The New Jersey Zinc Co., New York, N. Y. (U. S. Nos. 1,161,885 and 1,161,886; Nov. 30, 1915.)

Mineral Export Tax in Peru

The mineral export tax, passed by the last Peruvian congress, became effective on Nov. 14, 1915. The export tax as finally fixed is a compromise between the first proposals of the government and those of the Sociedad Nacional de Minería. The exemption from taxation of zinc ores and zinc products, and apparently of lead in bars, is noteworthy. Through the courtesy of the *West Coast Leader*, a translation of the principal features of the new export-tax law (No. 2,187) is presented herewith:

Article 1—Mineral products and those derived from their treatment shall be subject to the payment of duties in the form and proportion determined by this law.

GOLD

Art. 2—A. Metallic gold in any form, shall pay a coinage fee of Lp. 3 per kg. of fine gold, and if exported, Lp. 10 per kg. [Lp., libra peruana, equivalent to the British pound sterling when exchange is at a parity.]

B. Gold contained in bars of other metals, in matte and other metallurgical products, shall pay an export tax of Lp. 2 per kg. of fine gold.

SILVER

Art. 3—Metallic silver, in whatever form, shall pay for each kilogram of fine silver exported, a tax of 1 shilling, starting with the quotation of 23½d. per standard ounce troy, 925 fine, increasing 2½d. per kg. for each 1d. rise in the price of silver.

Sulphates of silver from lixiviation processes shall pay an export tax of 3d. per kg. of gross weight, starting from 23½d. per standard ounce troy increasing 1d. per kg. for each penny increase in the price of silver.

COPPER

Art. 4—Metallic copper, pure or impure, in any form, shall pay an export duty from the moment that the quotation of standard copper in London is Lp. 60 per ton, as follows: on quotation of Lp. 60 to Lp. 65 a tax of 15 shillings per ton of 1,016 kg., gross weight exported; and the duty shall increase by 2 shillings per ton for each pound-sterling increase in the quotation.

If the bars contain gold and silver, on the former there shall be paid the duty indicated in Clause B of Art. 2, provided that the assay is 10 grams or more per ton; and on the silver, when in excess of 2 kg. per ton, the following scale per kilogram of fine silver contained: 6d. when the quotation for silver is between 23½d. and 24½d.; 1 shilling when between 24½d. and 25½d.; 2 shillings when silver is quoted over 25½d.

Smelting products the copper contents of which may be in excess of 80% and less than 90% shall pay as export tax, on the fine-copper contents, the duty established for copper bars.

Cement copper and smelting products the contents of which in copper may be in excess of 60% and less than 80% shall pay, as export tax, 50% of the duty established in this article for copper bars, on each metric ton of gross weight.

Smelting products containing less than 90% copper, but over 80% copper, shall not be considered bars, but shall pay on the fine-copper contents the duty established for copper bars.

Mattes the contents of which in copper do not exceed 60% shall pay as duty, per metric ton gross weight, 40% of the duty established in this article for copper bars.

The gold and silver contained in smelting products the contents in copper of which may be in excess of 80% and less than 90% in cement and mattes shall pay an export duty as follows: Gold, the duty fixed in Clause B of Art. 2 of this law, provided that the assay is 10 grams or more per ton; and silver, 1 shilling for each kilogram of fine silver, provided the material contains 2 kg. per ton.

LEAD

Art. 5—Argentiferous-lead bars shall pay only on the silver contents at the rate of 1 shilling per kilogram of fine silver, and provided the bars contain 2 kg. per ton.

ORES

Art. 6—All other minerals, metalliferous or otherwise, shall pay an export duty of 2½d. per 100 kg., gross weight, and mechanical or chemical concentrates of any class, metalliferous or not, shall pay 5d. per 100 kg.

Coal, sulphur, ores of iron, manganese, and zinc are hereby exempted from the effects of this article, as well as their concentrates. The latter, if containing other metals subject to tax, shall pay the duty.

Ores of rare metals, such as tungsten, molybdenum and vanadium and their concentrates, shall pay Lp. 1 per ton, whatever may be their price in the market.

Borates exported from "salinas," Arequipa, shall pay an export tax of 2 shillings per ton.

PETROLEUM

Art. 7—Crude petroleum and the residues and products of its distillation shall pay an export tax of 1 shilling per metric ton, gross weight.

Exporters must declare the tenor of their products. Penalties for false declarations of the nature and grade of the mineral products are punishable by a fine of four times the correct tax, and the government may purchase the lot to be exported according to the assays declared by the exporter. The exportation of amalgams of all classes is expressly prohibited. Export duties up to £40 may be paid in gold coin, but above this amount must be paid "in drafts on New York at 90 days sight, or at the option of the shipper, in the equivalent drafts on London." The Chamber of Commerce of Lima fixes weekly the value of the ton of standard copper and of the ounce troy of silver, based on the quotations of the London Metal Exchange; this quotation rules for the following week.

Meeting of the Pan American Scientific Congress

The secretary-general has issued the following list of receptions arranged for the meeting in Washington:

Reception by the president of the congress, His Excellency the Ambassador of Chile, Señor Don Eduardo Suarez Mujica, at the Chilean Embassy, 1013 Sixteenth St., Thursday, Dec. 30, 4:30 to 7 p.m.

Reception tendered by the secretary and the Board of Regents of the Smithsonian Institution to the members of the congress Thursday evening, Dec. 30, at 9 o'clock.

Theater party by the Secretary of State and United States delegation to the Latin-American delegations at the New National Theater, Friday, Dec. 3, at 8:30 o'clock. Other members of the congress are requested to make their reservations at once with the management of the theater.

Reception tendered to the members of the congress by the president and officers of the Cosmos Club Monday afternoon, Jan. 3, at 6 o'clock.

Reception by the Governing Board of the Pan American Union to the members of the congress at the Pan American Union, Saturday night, Jan. 1, at 9 o'clock.

The members of the Second Pan American Scientific Congress will be the guests of the American Association for the Advancement of Science on the occasion of a special meeting to be held in Memorial Continental Hall, Monday night, Jan. 3, at 8 o'clock.

The trustees of the Carnegie Institution of Washington will tender a reception to the members of the congress Tuesday night, Jan. 4, 9 p.m., at Sixteenth and P St.

Friday night, Jan. 7, the president will give a reception to the members of the congress at the White House.

Saturday night, Jan. 8, the Secretary of State and the United States delegation will give a banquet to the members of the congress at the Pan American Union; hour to be announced later.

Editorials

Exploitation of Juneau Mines

The exploitation of the great gold lode at Juneau, Alaska, by several companies, but especially by the Alaska-Gastineau and Alaska Juneau, is a subject of interest not only to thousands of investors in the shares of these companies, but also to the engineering profession in view of the unique problem that is to be solved and the different ways of going about it. The problem itself involves the mining and milling at a profit of ore that is expected to average only about $1.50 per ton. Nothing like this was ever accomplished. If it be admitted that it can be done, the available tonnage of the Juneau lode is so great that its extraction will hardly be completed within the lifetime of this generation.

The Juneau lode (we use the term rather for convenience than out of any belief in its accuracy) is a great zone of slate permeated by veinlets, stringers and masses of gold-bearing quartz. Dikes of metagabbro have intruded themselves into the lode, which dikes in turn carry auriferous quartz. The distribution of the veinlets, stringers and masses of quartz is irregular. The mineralization is not, therefore, in any way comparable with that of the great deposits of disseminated copper ore, which are generally masses of rock more or less evenly peppered with valuable minerals. The only similarity of these two classes of ore deposits is that both are very large and are capable of extraction by the most economical methods known in the modern art of mining.

As in the case of the porphyry-copper deposits, the Juneau gold lode was no new thing. Attempts to get gold from it have been made at frequent intervals during the last 25 years. All such attempts, however, were directed on the idea of mining the quartz veins or enrichment zones alone, and upon a very small scale—none of the early mills being so large as those that are erected and run as pilot mills nowadays. The mining and milling of a very large tonnage is of course one of the essential factors in reducing costs and enabling ore so poor as $1.50 per ton to be treated profitably.

The Alaska-Gastineau (Alaska Gold Mines Co.) is contemplating mining and milling ultimately at the rate of 6 to 7 million tons per annum. The immediate plans of the Alaska Juneau company are laid out for the mining and milling of about 2,500,000 tons per annum.

Both these companies are directed by the most successful mining engineers of the time. At the head of Alaska-Gastineau is Mr. Jackling (aided by his great staff), who is known as the brilliant developer of the Utah Copper Co., Chino, Ray, and Butte & Superior. At the head of Alaska Juneau are Messrs. Bradley, Requa and Mackenzie, who are known as the developers of Nevada Consolidated, while Mr. Bradley has been for many years the manager of the Bunker Hill & Sullivan mine in the Cœur d'Alenes, and the Treadwell group of mines on Douglas Island, Alaska, just across the Gastineau Channel from the Juneau mines.

It was but natural that the two groups of engineers should have different ideas. They agree respecting the nature of the ore deposit and more or less as to the probable grade of the ore. They differ as to how the exploitation should be conducted in order to obtain the best results. The main differences may be summarized as follows: The Gastineau engineers are planning to do what may be called bulk mining—that is, extracting everything from the lode and putting it through the mill. In the mill they have introduced the novelty of crushing with rolls. The Alaska Juneau engineers, on the other hand, are contemplating what may be called selective mining—that is, extracting only the richer portion of the lode—but this will be nothing like the selective mining of the small concerns of 20 or 25 years ago. The extraction of ore will be prosecuted on such a huge scale that block by block it will be bulk mining, but the poorer portions of the lode will be passed by. The governing principle is excellently illustrated in the following statement of Mr. Bradley: "The cubic contents of the vein above the Gold Creek tunnel level and between the eastern and western ends of the property totals approximately 500,000,000 tons of slate, metagabbro and quartz. From this there should be mined, from selected places, 80,000,000 to 100,000,000 tons of vein matter and quartz suitable for milling that should yield a net profit of from 70c. to $1 per ton, depending upon conditions of mining that cannot at this time be estimated within closer limits of ultimate profits. Areas will probably be found in which mining may profitably be conducted by sorting, leaving two tons in the stopes for every ton milled. Other areas will probably be found, all of which may be mined without the necessity of mine sorting."

In milling, the Alaska Juneau engineers are going to adhere to the conventional stamps. We shall have, therefore, an interesting comparison not only of bulk mining vs. selective mining, but also of rolls vs. stamps.

In introducing rolls in the Gastineau mill, Mr. Jackling has done nothing revolutionary except in so far as the metallurgy of gold is concerned. There was a time when stamps were the common means for the fine crushing of all sorts of ore. For the milling of most ore except gold ore—and except also the Lake Superior copper ore, for which steam stamps still prevail—the stamp battery has been displaced by rolls, which mechanically are superior. Even in gold milling when ore is to be treated by the cyanide process, stamps were displaced by rolls, and the rolls in turn have been, in some cases, displaced partially by ball mills. Mr. Jackling has simply gone a step farther in introducing for a process of amalgamation and concentration the crushing machinery that has proved itself the better in other branches of the art. Mr. Bradley and his associates, on the other hand, adhere to the use of the stamp batteries, such as they are already employing on the other side of the Gastineau Channel.

Mr. Jackling has already demonstrated by the milling of something like 1,000,000 tons of ore that by his method the Juneau ore may not only be mined and milled at a

cost of 75c. per ton, as to which many engineers previously were skeptical, but also that it may be done for a considerably lower figure. In so far as the milling is concerned, however, it will be necessary to segregate its cost from the mining cost before the comparison between rolls and stamps may be made. The net result of both the mining and milling methods, however, will be expressed in the net profit per ton of ore, and that is the figure which is awaited with the most interest.

Rise in Ocean Freight Rates

The rise in transatlantic freight rates, and in ocean freight rates generally, equals the most spectacular rises in prices for the commodities. This is a matter of great concern in the mining and metallurgical industry. A seller of copper, for example, who agreed three months ago to deliver copper to Europe at this time, finds his proceeds much shrunken if he failed to contract for freight room in advance and is obliged to pay current rates. Freight rates have been rising since the beginning of 1915, but during the last two or three months the advance has been very sharp. Previous to the beginning of the war a common rate for carrying copper from New York to British ports was about 16c. per 100 lb. A couple of months ago it was about 60c. Within the last two or three weeks $1 and upward has been paid.

A pamphlet on "Ocean Shipping," just published by the National Foreign Trade Council, throws light upon the conditions. Quoting from that pamphlet, but not literally:

"The shipping capacity of the world previous to the war was estimated at 44,000,000 tons, fully two-thirds consisting of tramp steamships, of which Great Britain alone owned 40% of the whole. The war has removed from private commercial employment between 20 and 25% of the world's steam shipping, or upward of 9,000,000 out of 44,000,000 tons, owing to destructive immobilization and impressments for governmental service. On the other hand, the aggregate of freight to be carried has probably increased. It is known that the world's trade showed a huge falling off during the first year of war, taking value as the basis; but considering bulk alone, it seems that the volume of traffic handled by the world's merchant marine has increased considerably since the war began.

"The primary needs of armies in the field are food and clothing. Industrial resources are mobilized for the purpose of turning out equipment and ammunition. This operates to the detriment of agriculture, already depleted of men sent to the front, and hence there is increased importation of food and raw materials, which taxes the resources of an already busy merchant marine. Moreover, the available labor becoming scarce and poor in quality, the discharge of ships is not carried out with the accustomed dispatch. The closing of the Panama Canal by the earth slides in October, 1915, dislocated the world's shipping, for it delayed many vessels sailing on trade routes via Panama and compelled their diversion to destination by longer routes via Magellan and other points. Shipowners and shippers suffered heavy losses. These delays naturally exercised a bullish effect on freight rates in general."

The secretary of the National Foreign Trade Council refers to the advance in freight rates in this way: "Rates first sharply increased, then doubled, trebled, and in some instances have become from five to seven times as large as before the war. To other parts of the world American exports have not increased in volume. The transportation has decreased, due to shifting of vessels to the European trade, and rates have greatly advanced. Shipowners decline to make the long-term contracts characteristic of peaceful times, and shippers of manufactures are more embarrassed by their inability to make definite calculations of the future selling price of their products, which is affected by freight, than by the abnormal size of the rates themselves."

Precisely these conditions have been experienced in the export trade in the metals, besides which there are many incidental difficulties. For example, the congestion in the railway yards at the Atlantic seaports has introduced unusual difficulties in getting freight on board ships, even when the prospective shipper has engaged the room. He may be unable to cause the freight to be moved from the railway yards to the docks during the lay-days of the ship. The only known means of circumventing this obstacle is to cause the freight to be delivered at the dock many days, or even weeks, before the sailing date of the ship. Consequently the shipper is obliged to carry his commodities, with increased interest charges, for a longer time than he contemplates normally. It is expected that freight rates will go down after the war, but as to whether the drop will be sharp or gradual there is difference of opinion.

Block Signals for Tunnel Haulage

Two fatal accidents have occurred within the last few weeks at the Morning mine, in Idaho, under somewhat similar circumstances, emphasizing the necessity of safeguards in the operation of electric-motor haulage underground.

In the first instance a machinist had been called into the mine to make some repairs. When his work was completed, he telephoned the man in charge outside, a distance of over a mile, to know if the track was clear. Being informed that it was, he started out on the motor. The man outside had hardly hung up the receiver when it flashed upon him that the ore train had just started in. He hurriedly called up to correct his error, but too late. The machinist had started out, and there was no way to stop him and no way to prevent a collision. The collision occurred; the machinist was horribly mangled and died a few days later. While this man was waiting for death to relieve him of his suffering, a motorman was killed in the same tunnel by another collision. In this case ore cars were left on the track and another train crashed into them.

Both these accidents were due to the failure of the human agency and are likely to be repeated from time to time so long as human frailty is the sole dependence. The men who committed the errors that caused the accidents were discharged, but that gives no assurance that their successors will not make similar fatal mistakes. No company having long hauls by electric motors under ground has adopted all possible safeguards to prevent such accidents unless it has a block-signal system installed.

The installation of such a system for mine tunnels cannot be withheld on a plea of cost of installation, because that is comparatively moderate. At any of our metropolitan amusement parks the scenic railways are all equipped with efficient, simple little block systems, and their trackage does not begin to compare with that of any mine tunnel where motor haulage is used. The amusement railway is safeguarding a greater number of lives per day, it is true, but when the size of investment or the amount of gross income is considered, there seems to be little argument for the tunnel ore-haulage system not being equipped with automatic block signals.

BY THE WAY

Ty Cobb says: "No, I don't drink! It dims my batting eye." Efficiency and alcohol won't mix. The man who drinks is never a safe man, says the "Inland Steel Safety Bulletin."

⁂

The accompanying picture of Mrs. Carrie Everson was drawn by Arthur L. Ormay from a reproduction in the Denver *Times* of an original photograph. Carrie Jane Billing, later Mrs. Everson, was born in Sharon, Mass., in 1842, moving to Denver in the early '80s, and died in San Anselmo, Calif. on Nov. 3, 1914. It is reported that the Colorado Scientific Society purposes educating her grand-daughter.

⁂

That optimism and pessimism in mining ventures were "not born yesterday," is evidenced by the following extract from the diary of Samuel Pepys, under date of Oct. 3, 1660: "This day I heard the Duke [of York] speak of a great design that he and my Lord of Pembroke have, and a great many others, of sending a venture to some parts of Africa to dig for gold ore there. They intend to admit as many as will venture their money, and so make themselves a company. £250 is the lowest share to every man. But I do not find that my Lord do much like it."

⁂

According to *Coal Age*, among a number of applications received recently by a large coal-mining company was the following orthographic gem: Sir: I have bin informed by the Engr. Agency that you are in need of a Transetman. I would like to accept a passisian of that kind if you think me caperable of holding the passion. I have had Six Years experence in R.R. Const. and Loc. and am a fairly good drausman and have bin in mines with Mineing Engr. good many times. Can furnish you with rep. if need to. Yours Verry Truly,

P. S. Can report in verry Short notice 5 days.

⁂

In a recent market letter is the following straight tip:

These stocks should be bought, and bought at once, in order to take full advantage of opportunities now at hand. We believe that all of the simon-pure investment coppers are endowed with remarkable speculative possibilities for the trader who is content with market turns, while to the conservative investor with the income point of view in mind the present opportunity is one not to be overlooked. We believe that Calumet & Hecla is a buy up to $1,000 per share, Utah Copper to $150, Anaconda to $100, American Zinc to $100, Calumet & Arizona to $100, Chino to $100, Granby, Inspiration, Osceola and Quincy to $100, Miami to $75, Ray and Chili to $50.

East Butte should double in price very soon, also Corbin, Kennecott, Ray Hercules, New Cornelia, First National, Davis Daly and Goldfield Consolidated.

Among the many lower-priced mines and properties, we think well of Success, Caledonia, Marsh Mining, Utah Metals, Hecla, Iron Blossom, Kewanas, McIntyre, Vipond, Rex Consolidated, Chief, Majestic, Fortuna and Nevada Douglas.

Hope certainly does spring infernal, but why omit Con Mercur, Montgomery Shoshone and Ely Central?

⁂

The Serbs in retreating from northeastern Serbia are reported to have destroyed the surface plant of the copper mines near Bor, in the Department of Timok, and to have permitted the workings to be flooded to prevent the Teuton forces from availing themselves immediately of this source of copper. The principal mine is the Tchoka Dhulkan and belongs to a group controlled by the Cie. Française des Mines de Bor. There are numerous small deposits of copper in the Balkan states, but this company was the principal producer. Its output in 1912, according to the "Copper Handbook," was 16,699,845 lb. The smelting plant comprised four small water-jacketed furnaces, two of 110 tons' daily capacity and two 210-ton furnaces, and a converter department with one stand and four shells. In the latter part of 1912 most of the employees were ordered into the Serbian army for the Balkan war, and for a long time only one furnace was operated. Near Maidanpek, in the same general district, a 200-ton smelting plant was built in 1907 by a Belgian company, which used the Knudsen process and made a 96% copper product. This plant has presumably met with the same fate as the Bor property.

⁂

Dr. Branner's Retirement

The resignation of Dr. John Casper Branner, Leland Stanford University, takes place on Dec. 31. He has already taken leave of the campus and will be gone for an indefinite period. He was invited to make his home at Stanford after his retirement, but it is understood that he has declined, as he desires to have a complete rest, and to remain entirely away from the scene of his former labor. Within the past two years the presidency was added to his duties as professor of geology, and while the presidency of the university may be accounted an honor, it also added very largely to the labor.

Doctor and Mrs. Branner will visit New Orleans and Washington and they may go to Panama. Doctor Branner will attend the Pan-American Scientific Congress, which will open in Washington Dec. 27, under the auspices of the Government, and will contribute to the congress a paper on "Recent Contributions to the Geology of Brazil and Their Relation to the Development of That Country."

Doctor Branner is a member of the committee in charge of the congress and also the committee on Economic Geology. Prof. Bailey Willis, who will succeed Doctor Branner as head of the department of geology at Stanford, is also a member of the latter committee. Prof. G. H. Clevenger, of Stanford, is a member of the committee on Metallurgy and Dr. Margaret Schallenburger, California commissioner of education, is on the committee on Education of Women.

The Producers

Written Expressly for
THE ENGINEERING AND MINING JOURNAL
BY BERTON BRALEY

* * *

DOWN there in Wall Street the brokers is brokin',
Tradin' in copper stocks day after day;
Sidewalks is crowded an' offices chokin',
Chokin' with people that's gamblin' away;
Some of 'em's slidin' to wreck an' to ruin,
Some of 'em's makin' a million or more;
Meanwhile us miners goes right on a-doin'
What we are paid for—just diggin' the ore.

Over in Yurrup the nations is clashin',
Turnin' their world into several hells,
Killin' an' woundin' an' crushin' an' smashin',
Fillin' the air with the shriek of the shells,
Usin' up copper fer ruin an' slaughter,
Drenchin' the earth in a torrent of gore;
We got our job on this side of the water,
Doin' our duty of diggin' the ore.

Down in the stopes we are drillin' an' shootin',
Minin' an' muckin'—a hard-handed crew;
Up in the cages the ore goes sky-hootin',
Leavin' us plenty more minin' to do;
Danger an' death all around us is lurkin',
We gits our wages—an' nothin' much more;
Still it's our job, an' we keeps on a-workin',
Doin' our duty an' diggin' the ore.

Copper wires stretches all over the nation—
Over the world, if you want the thing clear;
Copper's the magic of civilization
Spread by the work of the wise engineer;
He is the guy that you have to give credit.
Heat, light an' power are part of his chore,
Wizard an' prophet an' dreamer—you've said it;
But—don't forget that we're diggin' the ore.

PERSONALS

J. R. Finlay, of New York, is at Bonne Terre, Mo., on professional business.

Arthur Thacher, of St. Louis, has returned from Denver and is now in New York.

H. A. Wheeler, of St. Louis, has been examining zinc properties in Central Missouri.

C. D. Bell, of Bonne Terre, Mo., has moved to Joplin, Mo., to take charge of a new zinc property.

Walter Strache has sailed from New York for an extended trip through Central and South America.

T. Skewes-Saunders succeeds André P. Griffiths as general manager of Las Dos Estrellas, El Oro, Mexico.

W. H. Seagrave, manager for the Kennecott Copper Co. at Kennecott, Alaska, has gone East on a vacation.

O. M. Bilharz, formerly superintendent of the St. Joe Lead Co., is now operating in the Missouri zinc district.

Frank A. Glass, has been appointed superintendent of the Wilcox mine of the Canadian-Cuyuna Ore Co. at Woodrow, Minnesota.

H. A. Buehler, state geologist of Missouri, is giving special attention to the Joplin zinc district, in coöperation with the Bureau of Mines.

A. P. Rogers has returned to New York from South America where he has been for about a year on the West Coast, chiefly in Peru and Bolivia.

Dr. C. Offerhaus has finished the erection of the Kwarzchana copper plant of the Siemens Successors at Kwarzchana, Caucasus, Russia, which was designed by him, and has returned to Germany.

H. W. Hardinge has been honored by the Franklin Institute and the City of Philadelphia, being awarded the John Scott medal and maximum cash premium for the invention of his conical mill.

Charles A. Gibbons, Jr., has resigned his connection with the Central Chili Copper Co., Panulcillo, Coquimbo, Chile, where he has been in charge of the mining department for three years past. Mr. Gibbons will be at his home at Taunton, Mass., for the present.

W. R. Rust is reported to have resigned from the Tacoma Smeltery and the Guggenheim interests entirely. The Chichagoff Mining Co., is one property that Rust is personally interested in and indications are that he will enter other parts of Alaska in mining propositions, and possibly start an Alaskan smeltery.

Frederick G. Clapp, managing geologist of the Associated Geological Engineers, has recently completed some explorations in Texas and has gone to Elgin, Kan., where the Associated Geological Engineers are doing extensive geological work. Clyde T. Griswold of the Mining Department in the Carnegie Institute of Technology and Ralph W. Richards of Washington, D. C., are included in the party.

On Jan. 1 Russell Wayland takes P. R. Bradley's position as general superintendent at the Alaska Treadwell and the latter becomes consulting engineer for the two companies, succeeding J. H. Mackenzie in that office. Mackenzie becomes president of the Alaska Treadwell. L. H. Metzgar succeeds Wayland as assistant superintendent at Treadwell. David Landsburg remains as mine superintendent at Treadwell.

M. F. Chase, general manager, and Walter D. Main, assistant general manager and sales manager, of the Mineral Point Zinc Co. have resigned. Mr. Chase has been with the company for 17 years and has been in charge, for some time past, of all of the manufacturing operations of this and its allied companies in Illinois, Wisconsin, Kansas, Oklahoma and Ohio, while Mr. Main has similarly supervised the sales and commercial end of these subsidiaries of the New Jersey Zinc Co. No announcement has been made as to their future business but it is reasonable to suppose that it will be along the same ground lines in which they have become proficient.

David Schenck Jacobus, last week elected president of the American Society of Mechanical Engineers, was graduated from the Stevens Institute of Technology in 1884 and served that institution for 22 years as instructor and professor, retiring in 1906. For six years also he had charge of the Carnegie Engineering laboratory. Since his retirement from Stevens Institute as professor emeritus in 1906, Dr. Jacobus has acted as advisory engineer for the Babcock & Wilcox Co., with office at 85 Liberty St., New York. He also continues as a special lecturer in experimental engineering at Stevens Institute. He is a member of many other technical societies and the author of numerous papers.

OBITUARY

Gottfried Voland, head of the firm of Voland & Sons, manufacturer of balances, died Nov. 26, at New Rochelle, N. Y., aged 62 years.

Edward Smith died at Buffalo, N. Y., Dec. 5, aged 70 years. He was for many years connected with transportation on the Lakes and had been president of the American Ship Building Co. for two years past.

J. L. McCleary died at Virginia City, Nev., Dec. 6, aged 79 years. He was born at Lancaster, Ohio, went to Nevada over 50 years ago, and has lived at Virginia City and Candelaria ever since. For many years he had charge of the Virginia City water-works.

Edward Biddle died at Dallas, Oregon, Nov. 15, aged 71 years. He was born at Greece, N. Y., and when 24 years old went to California. Later he went to Virginia City, Nev., and was employed for several years as engineer for the Sutro Tunnel Co. From there he went to Oregon and established the Dallas Iron Works which he conducted for over 25 years.

George J. Maas, of Negaunee, Mich., died Dec. 2, aged 54 years. He was well known in the Lake iron country, where he did much exploring and developing. He produced a number of inventions which he patented, one being an instrument to determine the direction taken by a diamond drill bit, which is used the world over. He was born at Marquette, Mich., and had lived in Negaunee since he was three years old.

William A. Conner died at Plainfield, N. J., Dec. 8, aged 56 years. He was born in Baltimore and began his business career in Pittsburgh in 1876, when he entered the oil refining business, in which he reached the position of assistant manager for the Standard Oil Co. He took charge of the first plant built by the Standard Underground Cable Co. in Pittsburgh, and up to the time of his death was head of the manufacturing business of that company, including the operation of large plants planned and built by him in Pittsburgh, Perth Amboy, N. J.; Oakland, Calif., and Hamilton, Canada.

James Mapes Dodge, chairman of the board of the Link-Belt Co., died at his home in Philadelphia, Dec. 4. He was born in 1852, at Waverly, N. J. His grandfather was Prof. James J. Mapes, a noted chemist and scientist, and his mother, Mary Mapes Dodge, a well known author, for many years editor of the "St. Nicholas Magazine." Mr. Dodge spent three years at Cornell University and a year at Rutgers. At the latter institution he took a special course in chemistry under the late Professor George H. Cook, state geologist of New Jersey. After spending a short time at the Morgan Iron Works in New York, he entered the shops of John Roach, the shipbuilder, at Chester, where his marked mechanical ability and ingenuity brought him rapid advancement. Shortly after the Centennial at Philadelphia he went to Chicago. It was here that he formed the acquaintance of William D. Ewart, the inventor of the Ewart link-belting, and soon after he joined hands with Mr. Ewart and his associates in the development of the chain business. Mr. Dodge's early work was confined principally to development and manufacture, and here his genius had full play. New chains, new methods of manufacture, and new conveying and elevating appliances were brought out in rapid succession. After this period of development Mr. Dodge went East and entered into partnership with Edward H. Burr under the firm name of Burr & Dodge, representing in Philadelphia the Ewart Manufacturing Co., of Indianapolis. Out of this partnership grew the Link-Belt Engineering Co., organized in 1888. It was in 1889, after having become thoroughly acquainted with the needs of the anthracite coal industry, that Mr. Dodge developed his system of storing anthracite coal in large conical piles, and reloading it by machinery, accomplishing this result with little labor and practically no breakage. The invention was so complete, and yet withal so simple, that it is still without a rival in the field of anthracite coal storage. For this meritorious invention he was presented with the Elliott Cresson Gold Medal, in 1907, by the Franklin Institute. Though for many years a large employer of men, Mr. Dodge never met with any strikes or other labor difficulties. He was deeply interested in the personal welfare and advancement of his associates, and a conspicuous leader in the general introduction of the best elements in scientific management, having the double purpose of producing greater efficiency in the mechanical and human equipment, and greater pay with shorter hours and improved conditions for the men.

Editorial Correspondence

SAN FRANCISCO—Dec. 8

Increase in Miners' Wages has been voluntarily announced by several of the large mines in the Grass Valley district, Nevada County. Notices were posted at various mines on Dec. 3, announcing that all the large companies of the district will follow the lead of the North Star. The minimum wage for underground men will be $2.50 per day; men working in drifts $2.75. It is believed that the scale will reach $3 soon. There are 1,067 miners employed in the district and it is probably safe to say that not a half dozen of them are dissatisfied.

Salmon River Quartz Mines not prepared for winter work are closing down for the season, including the Homestake, Cub Bear, Trail Creek and Black Bear. A few men are left in each mine to do general work and look after the property. The closing down, which might otherwise have been avoided was caused by heavy snow storm in the first half of November on the north of the summit of the divide between Etna and Sawyer's Bar. The snow was followed by rain and sun and settled to a depth of about 4 ft., which makes it impracticable for travel without the use of a shovel. Motor stages have been discontinued. The mine owners in this district will take up the matter of opening a wagon road from Salmon River to connect with the Humboldt road which is now within a few miles of the boundary between Siskiyou and Humboldt County. The county supervisors will be asked to aid in this road improvement which is necessary to the proper development of the district. Siskiyou County is a large and rich county in minerals that can never be fully developed without good roads, and these must be built with the assistance of the county or state unless the mines are taken over by large investors.

Prices of Oil and Oil Products made a sharp advance at the beginning of December, said to be due to shortage of production in November, the total being more than 1,000,000 bbl. less than the actual sales in the month. The Oil Industry Association is inclined to predict further advance in prices, unless Congress gives relief to operators and prospectors against whom suits have been brought on lands within the withdrawal order of President Taft. In support of the contention that the shortage is the direct result of the refusal of the Government to permit development and the attempt to seize the wells developed, the association cites the fact that for the first time in years the California monthly production of oil is less than the actual sales. The fact is that the activity of the Government in the withdrawal of oil lands and the suits against holders of such lands have had very little to do with the shortage of production in either October or November. The production has been curtailed by order of the Independent Oil Producers Association and the advice of the large marketing concerns. The curtailment began immediately after the declaration of war in Europe. The advance in prices of oil and oil products is due to the fact that the Standard and the Union and the Associated and the Shell, who are all manufacturers and marketers, have decided to raise the price. The shortage of production has given them the opportunity.

Manganese, Magnesite, Chrome, Potash, Antimony and other industrial mineral substances produced in California are attracting a good deal of attention and comment, and the impression obtains among persons unacquainted or ill-advised that California is going to supply the world with these various substances just as soon as the investors come forward with the necessary means, money and machinery, for opening and developing these various deposits. The attention of large corporations has been called to both manganese and magnesite and also to antimony deposits in the past year and no doubt there will follow a thorough and careful examination of the possibilities of large production. In several instances small mines, long idle, have been reopened and some new properties opened, and the extracted ores shipped to the Eastern market. In fact several deposits not generally heretofore known, have been recently producing sufficient ores to pay a profit above the cost of extraction and shipment by motor, rail and water. The demand for manganese and magnesite ores has naturally increased in the past year and this has attracted attention particularly to California because there has been in the past only a comparatively small commercial production of these substances. The newspaper talk of California supplying the world with these and other minerals will not be looked upon seriously by large investors, although it is possible of course to very largely increase the production of all industrial minerals and metals which are or may be produced here.

New Railroad Construction is contemplated in the filing of articles of incorporation at Modesto, in Stanislaus County, by the Patterson & Western R.R. Co., a subsidiary of the Mineral Products Corporation. This company is developing deposits of manganese and quicksilver at Red Mountain, which is situated in Santa Clara County. The mineral deposits in this district are in Santa Clara, Alameda and Stanislaus Counties. Quicksilver was mined in this district 15 or 20 years ago by Alvinza Hayward and others. Manganese has been produced in this or adjoining districts for several years and within the past two or three years development of magnesite has been undertaken and is still in progress. Motor-trucks are being employed to handle the ores over roads that are not in good order, and which probably never will be put in order unless the operators of the properties bear the expense. The counties of Stanislaus, Santa Clara and Alameda could well afford to build first-class wagon and automobile roads, not only for the benefit of the mines that could be developed, but for the benefit of the automobile tourists who could and would take advantage of some of the finest scenery in the Coast Range of mountains. It is evident, however, that the counties will do very little toward such road building before it is too late to be of direct benefit to the development of the mineral deposits. So the operators are preparing for the construction of a railroad about 25 mi. long to run between the town of Patterson and Red Mountain. Rights of way have been secured, with the exception of one strip of land and condemnation suit has been brought in order to secure this right of way. The mineral deposits in this district have been known long enough and have been sufficiently developed to attract investors, but like many other districts in the state, the lack of transportation facilities has been a handicap which requires a large investment to overcome. In most cases the extensions of railroads into mining camps have been necessarily done by the operators of the mines or quarries and have not always been operated successfully. The development of mining property and the conduct of the railroad have not usually been advantageously combined; and it has been difficult to induce the large railroad corporations to undertake transportation by rail from such districts until the project has been proved a successful venture.

BUTTE—Dec. 9

Near Big Arm, South of Flathead Lake, extensive prospecting in early part of year resulted in location of more than 100 claims, some of them showing good mineral at surface. Veins carry gold silver and copper, gold being principal content at the surface. Veins range in thickness from 6 in. to 3 ft. and assay from $10 per ton to over $400. An area of over six square miles is known to be mineralized.

In the Scratch Gravel District, Lewis and Clark County, nearly 200 men are prospecting or developing claims. At Head property of Scratch Gravel Gold Mining Co., all machinery has been installed, with exception of pump, and hoisting will be resumed soon. Company expects to ship between 450 and 500 tons of ore per month. The Rock Rose Mining and Milling Co., of Helena, which owns a group of six claims adjoining Fort Harrison, expects to resume development work at its property. J. H. Rowland has started operations on Conrad property owned by Conrad estate which adjoins Franklin of the Cruse estate. Ore assays as high as 104 oz. silver. At Sunshine mine T. B. Miller and associates are sinking new shaft and have already encountered a 14-in. vein, carrying well in gold and silver. Men are at work on group of claims operated by Frank Donaldson, north of Cruse property, Brown Bros. of London, England, and a number of New Yorkers, owners of the Oriole mine, have started operations. The reopening of that mine, which has lain idle for 35 years indicates the prediction that by a concerted effort of the Helena people outside capital for the development of meritorious mines would be attracted, has come true. The Oriole claim is located within a short distance of the Lexington which has produced in past years more than $600,000 in

lead and silver. While the Scratch Gravel district is at present the center of attraction, other districts around Helena are by no means neglected. In the Marysville district the Piegan-Gloster mill of the Barnes King Development Co. is operating regularly.

SALT LAKE CITY—Dec. 10

A New Operating System is to be tried at the Chief Consolidated at Tintic, according to which the handling of all development work will be done under contract, leaving the regular forces free to devote their entire attention to the mining of ore already developed. It is thought that a considerable saving and better progress will be made in doing development under this arrangement.

The Enlargement of the Potash Plant 100% is called for by plans being drawn for the Mineral Products Corporation at Marysvale. As soon as the officers and the engineers work out the details, the contract for the building of the second unit to the only commercial potash plant in the United States will be let to Westinghouse, Church, Kerr & Co., according to the Salt Lake "Tribune." Howard F. Chappell, president of the company, has been in Salt Lake City, where a conference was held by Mr. Chappell, C. H. Macdowell, vice-president of the company representing the Armours; S. J. Jennings, vice-president, representing the United States Smelting Co., and R. B. Forsythe, general manager of the mine and plant. It was decided to go ahead at once with the construction of the additions, which will increase the output to 60 tons a day, but before the plans shall be drawn the engineers will contrive a new system of devices for conveying the alunite ores into the roaster. "We are more than pleased with the plant and our decision to double the capacity as soon as the details are worked out shows that we are successful," said Mr. Chappell. "We are shipping an average of three carloads a week from Marysvale to Jacksonville, Fla., and as the potash market is higher than ever before we are enjoying the benefit of the high price. I have been over the new discovery of alunite at Marysvale, and while it is a good ore, yet we took samples from it a long time ago and decided that the claims which we are working are higher in potash. We will add to the factory as we think the trade demands." Mr. Chappell would not comment upon the plant which the Southern Cotton Oil Co. is erecting on Great Salt Lake to extract potash from the waters of the lake

HOUGHTON, MICH.—Dec. 8

There Is a Renewal of Interest in the Work at the Lake Copper mine. Its remarkable showing of copper brought about exploration work in numerous other neighboring properties. Four months ago Lake was reopened under the management of Elton W. Walker, who made such a record in his handling of the Mass Consolidated. At the present time Lake is shipping copper rock at the rate of 8,000 tons a month. The rock averaged during November more than 40 lb. of mineral to the ton, which insures more than 25 lb. refined copper. The underground work has been pushed along as rapidly as possible. While comparatively limited advance openings have been made, practically every drill now breaking rock underground is operating in very high-grade amygdaloid. Of course the lode is different, in many characteristics, from any other lode in the Lake Superior district and there is much bunching of the rich spots. Over half of the drills are working today in the places that it was found necessary to abandon when the slump in the price of metal made necessary the suspension of all operations at Lake. In addition to the regular rock tonnage, the Lake has been taking out a substantial amount of mass copper, four large shipments already having been made to the mill, so that while the net refined showing in the smeltery is better than 25 lb. this total ought to be augmented to some extent. The plan for the present is to continue the openings gradually, as good showings develop and to increase rock shipments accordingly.

That the Wolverine Company plans to absorb the White Pine Extension, as an evidence of the expansion policy of the Stanton management, is positively denied. In the first place the Stanton management is willing to go on record to the effect that the Wolverine has a productive life of from 17 to 20 years. There is no doubt at all that the policy of seeking copper rock in the footwall, and back of the footwall, is working out very satisfactorily and has added materially to the length of life of the mine. It will take at least five years to open to the bottom of the property and 12 to 15 years to mine back to surface and plans are being made accordingly. The Michigan management of the White Pine Extension property, will at the same time, be in charge of Theodore Denglar, who has been in charge of the Wolverine and Mohawk properties of the Stanton interests for the past few years with such excellent results. Fred B. Close, who has been active in the diamond drilling and original development work at the Extension property will be superintendent in charge and will make his permanent residence in Ontonagon county within the week. William R. Bolley, formerly superintendent of the Baltic mine of the Copper Range Consolidated will be assistant superintendent, thus assuring the White Pine Extension as efficient active management as is possible to secure, in addition to the strength of the Stanton control in the east.

The Inclination and Desire of Lake Superior Shareholders of the Adventure property to have some actual operations started likely will find expression in a public letter addressed to the shareholders in the near future. The Eastern management evidently does not feel the necessity for taking any aggressive action at this time. Renewal of interest in explorative prospects at the Adventure has come about through the latest developments at the South Lake property, which last week cut the Butler lode and found it containing fair copper rock. While on lateral development of this lode on the South Lake, has as yet been done, the showing where the cut was made was better than anticipated and fosters the belief that this formation will have commercial merit for South Lake. This adds another to the list of formations which are well developed and commercially profitable at South Lake on the one side and at Mass on the other side of the Adventure. Each of these lodes may be cut from the Adventure's present underground openings. A 500-ft. crosscut from any of the lower levels could be accomplished at comparatively small cost and would illustrate the worth of these formations. At present, with so much talk of the South Lake's various showings and the proof in mine production at the Mass Consolidated, the desire that some activity should take place at Adventure is well founded. The Lake Superior shareholders believe that if the Eastern management persists in a do-nothing policy now, there never will be a chance for activity at the mine. Engineers here acquainted with the conditions believe that Adventure, with the present metal market, could be operated on production from abandoned openings with success. The proposal freely suggested in the Michigan district is that management be passed to the shareholders here who desire renewed operations and are willing to pay an assessment for that purpose.

PIOCHE, NEV.—Dec. 6

The Old Day-Bristol Properties during the year passed from Receiver H. E. Freudenthal to the Consolidated California-Nevada Co., Geo. E. Bent, superintendent. The 2-mi. tram, eliminating a 15-mi. haul, is being operated successfully, and several new orebodies have been recently developed on the properties. The production is about 1,000 tons of good-grade copper ore per month and conditions indicate a larger production in the future. A mill has recently been installed on the old Comet property which is successfully separating and concentrating lead-silver-tungsten ores. E. D. Smiley is manager. During the year there has been considerable activity in the Groom district, owing largely to a lease by Tom McCormac on the old Poucin property. The lease has shipped several cars of high-grade lead ore since a road to Indian Springs on the Las Vegas & Tonopah R.R. has been put in condition, and the opening of the road has encouraged prospectors to start work on adjoining claims. During the latter part of the year two motor trucks were put on the 80-mi. haul from the old Briscoe property to Pioche, and an average of about 100 tons of high-grade silver-lead ore will be shipped monthly. In October about 15 men were put to work sinking the main shaft on the Atlanta ground, and Supt. J. J. Stubbenbord advises that the force will probably be increased in the near future. There is already developed on the property a considerable body of low-grade gold ore, but cheap power must be secured to make it pay. A new compressor has recently been installed. Considerable development work, with satisfying results, has been done on the old Easter property since the installation of machinery. J. W. Taylor is in charge.

TORONTO—Dec. 11

With the Freezing of the Yukon River, the winter highway to the railroad terminus at White Horse was opened Dec. 6, three horse-drawn stages moving each way.

Coincident with the Reorganization of the Canadian Shell Committee, which has been superseded by a new body to be known as the Imperial Munitions Board, a commission has been created to inquire into the supply and sufficiency of raw material in Canada required for the production of munitions of war and the best methods of conserving the same. The commission includes Col. Thomas Cantley, president of the Nova Scotia Steel and Coal Co. as chairman; E. Carnegie, of Welland, Ont., George W. Watts, of Toronto, Robert Hobson, of Hamilton, Ont., Senator Wm. C. Edwards, of Ottawa, and George C. Mackenzie, of the Canadian Mines Department.

The Mining News

ALASKA

THOMAS CULROSS (Fort Wells)—Will install machinery. J. B. Howard will be in charge of installation.

E. E. FLEMING (Chichagof Island)—Sinking shaft on gold-copper property about 14 mi. from Chichagof mine. Will work all winter.

J. A. HERBERT COAL MINE (Seldovia)—Shipping coal to Seward regularly, where it is marketed by A. G. de Sherbinin. Quality of coal improving, as expected, on getting further in from outcrop

ALASKA PETROLEUM AND COAL CO. (Katella)—This company has just been given patent to its coal claims in Behring coal field. Property is about 20 mi. from salt water and on proposed extension of the Copper River & N. W. Ry. T. S. Lippy, of Seattle, is president, and C. E. Davis, secretary.

C. O. HOLDING AND DEVELOPMENT (Juneau)—Incorporated with capital stock $1,000,000. Principal office, Dover, Del. John McLaren, Lewis Schulder-Frei, and E. M. Beyhl, of 154 Nassau St., New York City, are principal stockholders. E. H. Austin, president; A. N. Ward, secretary, and J. K. Nevill, Alaska, agent. Has bought and will develop Lemon Creek properties.

ARIZONA

Cochise County

SOUTH VIRGINIA (San Simon)—Moffitt and Creswell are shipping about four cars per month copper ore to El Paso smeltery. Mine is situated just north of Johnny Bull property, about 6 mi. southwest of Steins, N. M

Gila County

IRON CAP (Globe)—New, double drum hoist, 1,500-ft. capacity, together with other new equipment ordered.

OLD DOMINION (Globe)—Copper production for month of November amounted to 2,443,000 lb.; smallest this year since May.

ARIZONA COMMERCIAL (Globe)—The company is considering plans for the construction of a power plant. Power is now purchased from the Old Dominion.

INTERNATIONAL SMELTING (Miami)—One of three reverberatory furnaces is in operation. Cottrell condensing process is used in flues leading from roasting furnaces and converters, but not in flues leading to reverberatory stack.

Greenlee County

CLIFTON-MORENCI-METCALFE strike situation remains about the same. Strikers indulging in manhandling nonsympathizers and defying law and order generally, though no spectacular breaches.

Maricopa County

MAX DELTA (Phoenix)—Mine 6 mi. south of Phoenix has resumed sinking and drifting.

Pima County

CAVILLO (Tucson)—Cavillo mine, 40 mi. west of Tucson, which has been shipping 40 tons a week, has been sold.

RAY-ARIZONA (Kelvin)—Small force of men recently put on at development. Claims adjoin Kelvin Sultana on the west.

RAY-HERCULES (Ray)—Two new churn drills to be put into service soon. Shipments of carbonate ores by leasers continue.

Yavapai County

WHITE SPAR (Prescott)—Being reopened for its antimony ores.

CHAMPION (Prescott)—Active operations begun. Property recently changed hands.

MOUNT UNION (Prescott)—To be reopened by English syndicate after several years' idleness.

PEAT (Cherry Creek)—Contracts let for considerable development work, including 500-ft. of sinking.

LADY ALLOY (McCabe)—Carload ore averaging $16 gold, $6 silver and 3% copper was shipped to Copper Queen smeltery last week. Will continue to ship carload per week.

CALIFORNIA

Amador County

CHROME DEPOSITS in Mountain Springs district are being developed by J. E. Medford of Ione.

ALLEN (Ione)—New shaft is down to 500-ft. point. Prospect of developing good copper-bearing ore

ORO (Plymouth)—Reported that this property will be reopened by Kennedy Mining and Milling Co., of Jackson.

RHETTA (Plymouth)—Formerly Bay State, is being reopened and equipped with modern machinery. Bayliss C. Clark is superintendent

ONEIDA (Sutter Creek)—This old mine reopened two or three years ago by South Eureka Co., but idle for past year, will be unwatered and further development undertaken by deepening shaft and exploring below lowest levels.

Butte County

FORBESTOWN CONSOLIDATED (Forbestown)—Reported sale of property including Gold Bank-Golden Queen and the Shakespear group and some placer ground made to C. W. Reece, of Salt Lake City for $270,000. Reopening and development of these mines has been in progress by M. J. Cooney, of Forbestown and Fred J. Stoer, of Oakland. Gold Bank-Golden Queen was chief producer in early days of quartz mining in Forbestown district.

Eldorado County

GOLDEN HATCHET (Placerville)—Will unwater shaft with a gasoline driven pump.

EUREKA SLATE (Placerville)—Large order of slate for Government warrants reopening quarries at Slatington. Improvements of tramway will cost $5,000. Motor trucks will haul product from end of tramway to Placerville for shipment by rail.

Inyo County

WILSHIRE (Bishop)—Operation suspended for winter; only watchman now at mine. During past season average battery assay $11.40 per ton; 5,000 tons mined and milled, producing a total of $55,000.

Kern County

BLACK HAWK (Randsburg)—Cleanup of 8 tons of ore at Red Dog mill last week returned $2,000.

Nevada County

PERRIN (Grass Valley)—Will reopen this mine formerly known as Prudential.

Placer County

CRANDAL (Ophir)—Property sold at public auction was bought in by William Jull, administrator of estate of E. Jull for amount of mortgage and cost, $4,200.

Shasta County

BALAKLALA (Coram)—About 9,000 tons a month being shipped to Mammoth smeltery at Kennett. Employs 125 men. George S. Ferguson is in charge.

Sierra County

ALHAMBRA (Poker Flat)—Work in tunnel begun; will continue during winter. Mill to be erected next spring. Caulfield and McFarlane in charge for Senator L. V. Ulrey, of Pennsylvania.

Tulare County

PORTERVILLE MAGNESITE (Porterville)—Nine cars of magnesite amounting to 600,000 lb. shipped during last week in November.

Tuolumne County

HOPE (Sonora)—Arrangements reported for installation of new machinery, including compressors and pumps. George W. Weston is general manager.

YANKEE HILL (Sonora)—Gravel property reported been taken over by El Oro Dredging Co., of Oroville, Charles Helman, manager. Installation of California type dredge is contemplated.

Yuba County

A. B. C. MINE (Brownsville)—Mine formerly known as Solano Wonder, now owned by Shaw & Batcher and J. C. Campbell is being put in shape for operation.

COLORADO

Ouray County

CAMP BIRD (Ouray)—For quarter ended Sept. 30 crushed 8,110 dry tons ore. Receipts from sale of bullion and concentrates $291,786; working expenses, $86,121.

San Miguel County

TOMBOY (Telluride)—Return for month of November: Mill ran 28 days; crushed 12,000 tons of ore, yielding bullion, $42,000; concentrates shipped, $44,500; expenses for period, $59,300; profit, $27,200.

IDAHO

Shoshone County

SUNSET-BANNER (Wallace)—This group, adjoining Beebe group on Beaver Creek, has been bonded to John D. Beebe for $75,000.

AMAZON-MANHATTAN (Wallace)—Work resumed on this Carbon Creek property, recently purchased by Interstate-Callahan, which has also secured Blue Grouse group, lying between Amazon-Manhattan and Interstate.

CASTLE ROCK (Wallace)—Crosscut to vein from 200 level showed 6 ft. of 1% copper ore; now driving west to cut downward extension of chimney of high-grade ore found in upper level.

EMPIRE (Wallace)—Controlling Horst-Powell copper mine on Little North Fork, contracted for 600-ton crusher, 20-drill compressor and hoist. Construction of mill building under way, mill to be completed in May.

AMAZON-DIXIE (Wallace)—Plans to sink 500-ft. vertical shaft at point short distance west of raise, crosscutting to vein at 250 and 500 ft. If developments in lower levels are satisfactory, mill will be constructed. Wesley Everett is manager

IDORA (Wallace)—Company plans to pool 300,000 shares of issued stock, which will be sold for $22,500 to raise money to meet payment on mortgage and provide funds for further development. Sec.-Treas. Charles E. Mullette states that mine is in position to pay own way henceforth.

CEDAR CREEK (Wallace)—Stated in circular letter issued to stockholders that lower crosscut tunnel has been extended 1,125 ft. Will cut vein at depth of 1,100 ft. In upper tunnel, milling ore is exposed for 300 ft., and in intermediate tunnel for 1,000 ft. Winze 125 ft. deep for intermediate level, with 260 ft. of driving, also shows milling ore

INDIANA

CALDWELL CHEMICAL CO. (Evansville)—Is receiving bids on picric-acid equipment for new plant at Spottsville, Ky., which will have capacity of 100 tons per month. Equipment will include coke ovens, coal-tar stills, preheaters, condensers, phenol recovery plants, etc. C. O. Koegel, 202 Woods Building, Evansville, Ind., is manager.

MARYLAND

UNITED STATES GOVERNMENT has let contract for construction of 16 steel retorts to be used in manufacture of nitric acid at Indian Head smokeless powder factory.

MICHIGAN

Iron

OLIVER IRON (Ishpeming)—New hoisting plant to be installed at Section 16 mine.

IRON MOUNTAIN LAKE (Ishpeming)—Shaft work will be resumed first of year; now down 350 ft.; will go to 600

CLEVELAND-CLIFFS (Ishpeming)—Is in market for $200,000 worth of machinery; rock drills, sharpeners, hoists, compressors, etc.

VIRGIL (Iron River)—Operations will be resumed about Jan. 1 by Wickwire Mining Co. New property, shut down when slump came year ago, is being unwatered.

ATHENS (Negaunee)—Shaft is now down about 1,100 ft. About 90 ft. per month is being made. New skip hoist is to be installed. Thus far cage hoist has been doing all of the work. Shaft is being concreted. Will go down to 2,400 ft.

MINNESOTA

Cuyuna Range

FERRO (Ironton)—Now being unwatered. New machinery and boilers will be installed.

MANGAN IRON AND STEEL (Ironton)—Work started on lath shaft to be sunk on company's property, which adjoins Cuyuna-Mille Lacs.

MINNESOTA DEVELOPMENT (Manganese)—Has started drilling on lands west of Iron Mountain mine, where it has considerable acreage under option.

MEACHAM (Crosby)—After idlness of several years underground operation is being gotten ready for production. Has modern concrete shaft but has never shipped any ore. Operated by Rogers-Brown Ore Co.

Mesabi Range

TIOGA (Chisholm)—Last building has now been moved from property, and operations will start soon.

VICTORIA (Virginia)—After idleness of four years, this property of Republic Iron and Steel Co. now has 150 men working underground. Product being stockpiled.

ORDEAN (Virginia)—Two shifts, aggregating over 100 men, started on stripping operations at this property, immediately east of Sliver; 600,000 yards of overburden will be removed, and property will ship next season.

MISSOURI-KANSAS-OKLAHOMA

JAMES MURPHY MILL (Galena, Kan.)—Shut down for improvement; $5,000 to be spent. Three sludge tables to be installed.

SAMBO MINING (Joplin, Mo.)—Situated near Lincolnville, Okla. Has 30-acre lease on Buck land. Will install 300-ton mill; framework already up. Charles Hart is manager.

SILVER COIN MINE (Galena, Kan.)—Has struck large body of ore at 159-ft. level, sheet formation. Has been handling dirt over custom mills, believes mine now justifies erecting concentrating plant, expects to let contract soon for 150-ton plant.

W. B. BASH AND ASSOCIATES (Joplin Mo.)—Have obtained lease of Ewers forty near Lincolnville, Okla. Will expend $4,000 or $5,000 in improving mill already on ground. Shaft is down to 150-ft. level; expect to go to 250 where drill holes show 20 ft. high-grade ore.

NORTH EMPIRE (Galena, Kan.)—Land has been drained. Mill has been operating on tailings, but will now work on dirt from ground as well as tailings. Produced car and half of ore last week. Ground has been idle for several years; will be consistent producer from now on. E. H. Stearns is superintendent.

G. C. MOORE AND ASSOCIATES (Galena, Kan.)—Have taken 5-acre lease from the Southside Mining Co. Land situated on west forty. Will install pumps and drain ground; many shafts are already down to the 65-ft. ore level; expect to drain ground to 150-ft. level where good run of ore has been developed through drilling; will lease part of land to miners; expect to erect custom mill to handle ore after ground is drained and opened up.

MONTANA

Silver Bow County

ANACONDA COPPER (Butte)—Production of copper at Washoe and Great Falls in November was 24,400,000 lb., against 24,900,000 lb. in October. Total production for 11 months of 1915 totaled 229,200,000 lb.

EAST BUTTE (Butte)—On Dec. 1, company paid off last of its indebtedness of $500,000. Original debt created by purchase of Pittsmont property was $2,500,000, all of which has been paid off from earnings in past six years. Will soon 100-ton flotation plant in operation this week.

BUTTE & SUPERIOR (Butte)—In November broke [illegible] net records for production. Total tonnage of [illegible] 52,150, which is 5,000 tons more than any previous month. From this, 15,050 tons of concentrates, containing 16,000,000 lb. of zinc were produced. Payrolls are estimated at between $190,000 and $200,000.

NEVADA

Churchill County

NEVADA WONDER (Wonder)—During fiscal year ended Sept. 30, mine produced 58,124 tons, gross value, $812,119, average $13.97 per ton. Expenses were $503,335; profit $308,783. Miscellaneous income was $278 and milling company's profit $18,196, making total profit of $327,557 for year.

Esmeralda County

GOLDFIELD CON (Goldfield)—Preliminary estimate for November: 22,160 tons milled; gross value, $199,800; operating expense, $117,000; net realization, $52,783.

Humboldt County

FIRST DEEP WORK IN WILLARD to prove depth is about to be undertaken at Kaiser lease on Sheepherder's Dream. B. T. Godfrey, of San Francisco, has bought in on lease and is now bringing in hoist for new work. Last finds in ground indicate that old high-grade streak has been recovered and it is asserted that there are several thousand dollars in sight at present.

ROCHESTER MINES (Rochester)—Made third bullion shipment for month, three bars, valued at $3,600. Two previous consignments bring November shipments up to $33,600.

Lincoln County

DEMIJOHN CON. (Pioche)—Has had 10 men on development work for last six months, in course of which some ore has been extracted.

AMALGAMATED-PIOCHE (Pioche)—Has worked continuously entire year with force of 100 men; product argentiferous lead-zinc sulphides. High-grade sorted and shipped crude, but a considerable tonnage of low-grade accumulated. Some form of flotation process expected to solve treatment difficulties. H. R. van Wagenen is in charge.

YUBA LEASING (Pioche)—During year installed 100-hp. gasoline engine and compressor at old No. 3 shaft, and built and put into operation 50-ton mill to treat gold-silver-lead ores from its lease of old properties along Yuba dike now controlled by the Amalgamated-Pioche. Mill is working satisfactorily, and another unit may soon be added to treat custom ores. A. Y. Smith is manager.

PRINCE CON. (Pioche)—Working force of about 100 men during entire year, succeeded in putting Pioche back among dividend-paying camps after lapse of about 40 years. Large production, coupled with favorable market, has enabled this company to pay $125,000 in dividends during year out of its lead-silver-manganese production of approximately 125,000 tons. In meantime development work exposed additional bodies of low-grade similar to those now being shipped, and considerable high-grade has been located below water level. A 100-hp. gasoline engine added to equipment during year. Under management of M. C. Godbe.

Nye County

TONOPAH ORE PRODUCTION for week ended Dec. 4 was 9,497 tons, valued at $201,406, compared with 9,951 tons week previous. Producers were: Tonopah Belmont, 3,111 tons; Tonopah Mining, 2,675; Tonopah Extension, 1,850; Jim Butler, 1,100; West End, 705; North Star, 112; miscellaneous leases, 194 tons.

Storey County

MEXICAN (Virginia)—On 2,500 level west crosscut No. 2A started and advanced 10 ft. through porphyry and quartz of low assay; on 2,700 level similar work and results. Mexican mill crushed 368 tons of custom ore, average $22.83.

SIERRA NEVADA (Virginia)—On 2,500 level advanced west crosscut 8 ft. through low-grade ore, disclosed in bottom of face, averaging $94. Stoping continued in No. 1. Shipped 125 tons to Mexican mill, average $13.63.

OPHIR (Virginia)—On 2,500 level west crosscut from southwest drift driven 9 ft. with face in porphyry and quartz of low assay. North drift from winze station advanced 8 ft. in loose ground. Saved 372 cars of ore; shipped 320 tons to mill.

CROWN POINT-BELCHER (Gold Hill)—Saved 260 cars of mill rock from No. 1 stope, 1,600 level. In joint incline water was held 65 ft. below 1,600 level and repairs made between 1,400 and 1,500 levels. Jacket mill received 690 tons dump rock and 192 tons mine rock; 90 tons shipped to gloryhole from shaft bins. Bar of bullion shipped.

UNION (Virginia)—East crosscut from top of raise to 2,400 level extended 4 ft., face in ore, average $20. At 9-ft. point north drift driven 4 ft. in ore, average $35. South Drift driven 4 ft. in ore, average $65. Saved from this work 61 tons, average $41.50. Raise in No. 1 stope in $18 ore; 59 tons of ore saved, average $16.52. Saved from No. 2 and No. 3 stopes 43 tons, averaging $8 and 80 tons averaging $35.60.

NEW JERSEY

Hudson County

NATURAL PRODUCTS REFINING CO. (Jersey City)—Manufactuer of bichromate of potash and bichromate of soda, is building an extension to its plant; estimated cost of which is $50,000.

NEW MEXICO

Grant County

OCTO (Lordsburg)—Has begun shipping silver-lead ore.

SAN FERNANDO (Tyrone)—Has taken over from O. D. Warnock group of gold-silver-copper claims 5 mi. south of Tyrone and will deepen 92-ft. shaft. Vein in bottom of shaft runs $18 gold, 14 oz. silver and 18% copper.

PHELPS-DODGE (Tyrone)—Company is awaiting plans of townsite and houses from Grosvenor Goodhue, New York, before proceeding with extensive construction. Contract for

15 "American" houses to cost about $3,000 each has been let; about 25 stucco houses costing $2,000 have been completed. Parker hospital will soon be finished at cost of $58,000.

SAVANNA COPPER (Silver City)—Deal just consummated whereby company disposes of holdings in Burro Mountain District, aggregating nearly 2,600 acres. Property adjoins Phelps-Dodge holdings and has considerable deposit of disseminated copper ore developed by drilling. Burro Mountain acreage alone is being disposed of, leaving the Savanna company some valuable gold claims in Pinos Altos Mountains.

Lincoln County

WHITE OAKS CON. (White Oaks)—Incorporated in state of Delaware for $250,000, has been admitted to do business in New Mexico.

Otero County

IRON DUKE (Jarilla)—J. H. Parker is opening up iron deposits and will begin shipping to Pueblo soon as 1-mi. extension of 3-mi. Rock Island spur from Orogrande is completed. Road is now being graded.

TENNESSEE

Polk County

TENNESSEE COPPER (Copper Hill)—It is reported that large powder mill will be established at Copper Hill, Tenn., to utilize sulphur and sulphuric acid produced from smeltery fumes.

UTAH

Juab County

TINTIC ORE PRODUCTION for November was 482 carloads, estimated 24,100 tons, valued at $600,000, compared with 643 carloads in October and 506 cars in September. Shippers were: Chief Consolidated, 113 cars; Iron Blosson, 88; Centennial-Eureka, 68; Mammoth, 54; Eagle & Blue Bell, 52; Gemini, 26; Grand Central, 16; Gold Chain, 8; May Day, 8; Dragon Consolidated, 8; Beck Tunnel, 7; Bullion Beck, 5; Colorado, 4; Lower Mammoth, 4; Yankee Consolidated, 3; Carisa lease, 3; Victoria, 3; Eureka Hill, 2; Mineral Utah 2; Uncle Sam, 2; Black Jack, 1; Godiva, 1; Ridge & Valley, 1; Plutus, 1; Victor Consolidated, 1; Minnie Moore lease, 1; Utah Ore Sampler, 1 car.

CHIEF CONSOLIDATED (Eureka)—Preparations being made for development of large acreage recently acquired in east and north Tintic, greater part being near Lehi-Tintic, Selma and Delamar.

EMERALD (Mammoth)—Mineralized ground has been cut by drift on 1,000 level. Country rock is brecciated limestone, with quartz, iron and manganese. Development is in progress in winze from 700.

GEMINI (Eureka)—Pumps have lowered water in this property, and in Ridge & Valley to 1,700 level, and are able to take care of flow by operating 3½ hours a day. Shipments amount to about 1,500 tons a month.

MAMMOTH (Mammoth)—November shipments were 54 cars; 438 cars shipped during 11 months, last five months showing output more than double that of first six. Recent find of lead-silver ore on 1,500 level being developed, and on 400 level there is large body of low-grade copper ore from which shipments are to be increased. Copper ore in other parts of the mine carries from 8 to 10% copper.

LOWER MAMMOTH (Mammoth)—After payment of recently declared dividend of $10,000 there will be $5,000 left in treasury. Both company and leasers are producing zinc ore from between 1,500 and 1,700 levels. Lead-silver ore also being shipped. Development both on 1,000 and 700 levels encouraging. Raise from latter level will later be connected with 700, to afford better ventilation as well as opportunity of prospecting new ground in southern part of property.

Salt Lake County

SELLS MINING (Alta)—Development in ore continues in recent strike at this property, and drifting is being done in ore northeast and southwest. Width has not been determined, except at one point, where there was about 10 ft. of shipping grade. Ezra Thompson, president of Cardiff has bought 50,000 shares of stock.

CONGOR MINING (Bingham)—Is developing vein from 4,000-ft. tunnel of Montana-Bingham. Car of sulphide ore has been shipped, running well in copper, and carrying some silver and gold. Vein is from two to three feet thick, and there is more than 1,000 ft. on dip to surface. Drifting on vein north and south. Work is about 100 ft. from face of Montana-Bingham tunnel in Bingham Amalgamated ground, but dip or rise of vein toward surface it is thought will carry apex on Congor claims. Two sets of leasers are also working in Montana-Bingham tunnel at around 300 and 500-ft. points.

Summit County

PARK CITY shipments for the week ended Dec. 3 amounted to 3,284,056 lb. November shipments were 147 cars or 6,518 tons, 86 cars having been shipped over the Union Pacific, and 61 cars over the Denver & Rio Grande.

ONTARIO (Park City)—Centrifugal pump of 1,000-gal. capacity per min. has been ordered, and will be installed on 1,700-ft. level.

COLUMBUS EXTENSION (Alta)—Work is being done with view to cutting downward extension of orebody in old Toledo workings, reported to have produced $1,000,000 in early days of camp.

Tooele County

IN DRY CANYON DISTRICT near Stockton, regular shipments are being made from Ferguson lease on Mono Development, from Hidden Treasure, and Queen of the Hills; latter property producing zinc ore, running 40% or over. Wandering Jew has car of ore ready for market.

CANADA

British Columbia

BRITISH COLUMBIA COPPER (Greenwood)—Is outputting at rate of 350,000 lb. blister copper with smeltery working at one-third capacity. Company is planning betterments, to cost $1,000,000, including 200-ton concentrator at or near Copper Mountain and power plant at Princeton. Delay in starting construction caused by lack of transportation; has been officially announced that if Kettle Valley Ry. is not extended from Princeton to Copper Mountain, mining company will build aërial tram 9 mi. long to transport output of proposed mill.

Ontario

TEMISKAMING & HUDSON BAY (Cobalt)—Mine, which has been closed down for some months, is about to resume.

NIPISSING (Cobalt)—In November mined ore estimated net value $164,846 and shipped bullion from Nipissing and customs ore $275,767.

KERR LAKE—(Cobalt)—Pumping on Kerr Lake has ceased and further drainage will be limited to pumping out of surface water and mud from basin.

MOOSE MOUNTAIN (Sellwood)—Car of concentrates shipped to New York in hope of perfecting briquetting process, which has been principal difficulty. Experiments being made by John L. Baker.

HOLLINGER (Porcupine)—Usual four-weekly statement for period ended Nov. 4 shows gross profits $184,769, from treatment of 28,401 tons of ore; average value of $10.34. Working costs $3.29 per ton milled. Mill also treated 10,495 tons of ore for Acme.

BEAVER (Cobalt)—Quarterly report for period ended Nov. 30 shows cash on hand, $122,674; silver in ore on hand, at smelters and in transit 220,015 oz. Additions to mill have been completed and it is now treating 125 to 150 tons a day. Main shaft has reached depth of 1,235 ft.

DOME (Porcupine)—Statement for six months ended Sept. 30 shows 162,363 tons of ore milled from which was recovered $731,802; average, $4.42 a ton. Total income for period was $800,360 and net earnings $433,902. Production for November will show recovery of $160,000 from 28,900 tons; average about $5.50 per ton.

MEXICO

Chihuahua

ROSARIO (Guadalupe y Calvo)—Being redeveloped by English company, is doggedly plodding along, packing in machinery on burros from Parral a 14-day trip. Have been no military operations in that section recently. Foundation for 200-ton mill has been laid, and all machinery has been shipped; some already on the ground. This mine was opened up and worked about 75 years ago by two Scotch brothers named MacIntosh, but was abandoned before it was really developed. Deepest shaft is only 450 ft. while main working shaft is only 150 ft. or 75 ft. below river bed. Estimated old dump contains 365,000 tons of $10 stuff.

Sonora

PORT AGUA PRIETA during October passed 134 cars (4,689 tons) ore, valued at $1,201,000; consisted of copper, $722,000; silver, $293,000; gold, $186,000. Moctezuma Copper, Nacozari, lead with 104 cars. El Tigre shipped 55 bars gold and silver bullion.

CANANEA CONSOLIDATED (Cananea)—Train service between Naco and Cananea has been resumed but definite date of resumption of work at Cananea has not been decided upon, but expectations are to start up within a few days. Plant is in good shape after the Villa evacuation and can be started up without delay. Men have been notified to return ready to resume positions. Some supplies have already gone in to relieve the distress experienced after the confiscation of all available food stuffs by Villistas.

CENTRAL AMERICA

Nicaragua

LINDA VENTURA (Wawa)—Mr. W. B. Milliken is erecting cyanide mill at the Linda Ventura mines, Wawa River, Bluefields, which he expects to have in successful operation in February. He will then return to his Denver office.

SOUTH AMERICA

Chile

BRADEN (Rancagua)—In November produced 3,684,000 lb. of blister copper, compared with 3,726,000 in October.

PERU

CERRO DE PASCO (Lima)—Production in November was 6,000,000 lb. of copper. This is approximately 1,000,000 lb. larger than average monthly production heretofore.

AFRICA

Belgian Congo

TANGANYIKA CONCESSION (Katanga)—During 10 months ended Oct. 31, Union Miniere, subsidiary of Tanganyika Concession, produced 24,530,000 lb. of copper. Production for entire year 1914 was but 21,444,000 lb.; in the 15 months up to Dec. 31, 1915, output amounted to only 30,000,000 lb. October production was 2,606,000 lb. Plans in hand for enlargement of plant to enable production of 50,000,000 lb. during 1916.

Rhodesia

GOLD PRODUCTION IN OCTOBER is reported at 81,161 oz.; for the 10 months ended Oct. 31 it was 760,044 oz., or $15,770,110. Other mineral production for the 10 months was 153,048 oz. silver, 2,906 tons copper, 26 tons lead, 1,486 tons asbestos, 48,261 tons chrome ore and 331,029 tons coal.

ASIA

Chosen

CHIKSAN MINING CO. (Chiksan)—Has contracted with New York Engineering Co. for a 10-cu.ft. steel gold dredge, having clay bypass and resoiling equipment.

The Market Report

Metal Markets

NEW YORK—Dec. 15

All the markets were dull and uninteresting during the last week. In the cases of both lead and spelter, however, there were advances that are rather inexplicable.

Copper, Tin, Lead and Zinc

Copper—Business of moderate proportions was transacted from day to day both for domestic and foreign account. The aggregate was probably a little larger than in the previous week. Some considerable orders were placed by Connecticut brass makers, presumably for ammunition purposes. The price of the large producers is generally 19¾c., r. t., and considerable business was reported done at that figure, but in some quarters small concessions were made. There was a disposition in certain office to accept orders for February, March and April deliveries at further concessions, sales for February being reported at 19.55c., r. t., and for April at 19.50c., r. t. Sales in England were reported at £97@97½.

Copper Exports from the United States week ended Nov. 27 are reported by the Department of Commerce at 6,370,971 lb. The larger items were 3,547,331 lb. to France, 1,120,459 lb. to Russia and 608,226 lb. to England. Imports were 1,649,210 lb. metal and 3,280,789 lb. in ore and matte; 4,929,999 lb. in all, the largest receipts being from Peru.

Exports from Baltimore for the past week included 1,120,201 lb. copper to London; 9.538,535 lb. copper to Havre, France.

Copper Sheets, base price is 25c. per lb. for hot rolled and 26c. for cold rolled, with usual extras. Copper wire is 21@21½c. per lb., carload lots at mill.

Tin—A fair volume of business was done at prices which changed but little during the week.

Lead—On Dec. 14 the A. S. & R. Co. unexpectedly raised its price to 4.50c., New York, and all of the independent producers immediately followed. The reasons that induced this advance have been the subject of a good deal of conjecture. About the beginning of the month the demand for lead was very good and independent producers were getting premiums over the price of the A. S. & R. Co., and at that time an advance by the A. S. & R. Co. was looked for. During the following week, however, the market was softer and not only did premiums disappear, but also independent producers who quoted the trust price failed to get business. The advance of this week occurred in what was supposed to be a wobbly market; certainly it was a dull one from the viewpoint of the independent producers. However, the advance had the effect of bringing out a considerable volume of new inquiries. The best explanation of the advance is that the A. S. & R. Co. has sold so largely for export that it had reduced its available supplies in this country to relatively small proportions. There is reason to believe that the stocks of lead at the several refineries in the United States are now pretty low.

Spelter—Although the business done in this metal was relatively small, a rather sharp advance in price occurred without there being any good reason for it so far as anybody knows. The volume of business transacted was only moderate. It was partly for domestic account and partly for export. The bulk of the business was for deliveries in the first quarter of 1916. In the first part of the week round lots for January-March delivery sold at 14c. In the latter part there was a further advance. The price for prompt spelter rose from 15 to 16½c. Transactions for early delivery were relatively small. The spelter market is confused by operations of speculators and traders, and the resale offers by consumers through brokers and otherwise. Some of the producers quote only to consumers.

Zinc Sheets, base price remains at $22 per 100 lb., f.o.b. Peru, Ill., less 8% discount. Business has been steady, with good sales forward.

Minor Metals—Current quotations for **Bismuth** are $4 per lb., New York.—**Cadmium** is quoted as 7s. per lb. in London; $1.75@1.90 per lb., New York.—**Chromium** metal, 75c. per lb., New York.—**Cobalt metal,** 97% pure, is sold at $1.75@2 per lb.—**Magnesium,** pure, holds to a high price, $6 per lb. being asked.—**Selenium** varies from $2.50@3 per lb., New York, for large lots; $4.50@5 for retail quantities.

IMPORTS AND EXPORTS

Imports and Exports of the Minor Metals in the United States nine months ended Sept. 30, in pounds except platinum, which is in ounces:

	Imports		Exports	
	1914	1915	1914	1915
Nickel	28,197,471	38,966,138	21,474,688	21,259,631
Antimony	11,665,698	15,372,182	27,109	1,249,325
Aluminum	11,831,103	7,374,549	18,929	40,102
Quicksilver			27,000	180,491
Platinum, oz.	60,683	29,905	143	9

Exports include reëxports of imported material. Nickel and antimony include contents of ore, matte and regulus. Exports of aluminum manufactures—not included above—were valued at $724,219 in 1914, and $2,441,200 this year.

DAILY PRICES OF METALS IN NEW YORK

Dec.	Sterling Exchange	Silver, Cts. per Oz.	Copper	Tin	Lead		Zinc
			Electrolytic, Cts. per Lb.	Spot, Cts. per Lb.	New York, Cts. per Lb.	St. Louis, Cts. per Lb.	St. Louis, Cts. per Lb.
9	4.7150	56	19.45 @19.55	37½	5.25	5.15 @5.20	13.00 @13.50

13	4.7113	55⅝	19.45 @19.55	37⅝	5.25	5.15 @5.20	14.00 @16.00
14	4.7125	55⅝	19.45 @19.55	37¼	5.40	5.30 @5.32½	14.00 @16.00
15	4.7163	55	19.45 @19.55	37½	5.40	5.30 @5.32½	14.50 @16.50

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St. Louis is given as the basing point. St. Louis and New York are normally quoted 0.17c. apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash. The difference between the price delivered and the New York cash equivalent is at present about 0.20c. on domestic business. The price of electrolytic cathodes is 0.05 to 0.10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands. Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St. Louis being the basing market. We quote the New York price at 17c. per 100 lb. above the St. Louis price.

Silver quotations are in cents per troy ounce of fine silver.

Some current freight rates on metals per 100 lb. are: St. Louis-New York 17c.; St. Louis-Chicago, 6.3c.; St. Louis-Pittsburgh, 13.1c.

LONDON

Dec.	Silver	Copper				Tin		Lead		Zinc	
		Standard		Electrolytic							
		Spot	3 Mos.	£ per Ton	Cts. per Lb.	Spot	3 Mos.	£ per Ton	Cts. per Lb.	£ per Ton	Cts per Lb
9	26½	77⅛	77⅜	97½	20.54	166¾	166½	28	5.90	82	16.27
10	26⅞	76⅝	77¼	97½	20.55	168⅜	168½	27¼	5.85	82	16.28
11	26⅞	.....	.....	.....	.....	.....	.....	.....	.....	.....	.....
13	26 11/16	76⅛	76⅝	97½	20.53	166¾	166½	27¼	5.84	82	16.26
14	26 11/16	76⅝	77¼	97½	20.53	167¼	167½	28¼	5.95	86	18.12
15	26½	78⅛	79¼	98	20.65	167½	167½	29½	6.17	93	19.60

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 3 per cent. discount. For convenience in comparison of London prices, in pounds sterling per 2240 lb., with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4.80. £15 = 3.21c.; £20 = 4.29c.; £30 = 6.43c.; £40 = 8.57c.; £60 = 12.85c. Variations, £1 = 0.21½c.

Other Metals

NEW YORK—Dec. 15

Aluminum—Business has been rather quieter, though demand is still good, and prices have not materially changed. Quotations are 58@59c. per lb. for No. 1 ingots, New York.

The president of the Aluminum Co. of America announces that the company has already largely increased production, and is preparing to increase it still further, not including the Southern Aluminium Co. plant which will be completed later.

Antimony—Business has been steady but not especially active. Stocks are rather low, but seem to be sufficient for present needs; while some large lots are reported on the way from the East Chinese and other ordinary brands are quoted at 38@40c. per lb., New York. Futures are lower, about 34@35c. for February being named. Cookson's is scarce, and the small quantities available are held at 55c. per lb., New York.

Quicksilver—The market is strong and rather excited, while stocks are low and supplies slow in coming forward. San Francisco, the primary market, reports by telegraph sales at $120@130 per flask of 75 lb., with the market firm. New York quotation is $125 per flask for large lots; $130@135 per flask being paid for smaller orders. London price is £16 12s. 6d. per flask, with no discount from second hands.

Nickel—Business is good and prices steady. Ordinary forms are 45@50c. per lb., according to size and terms of order. Electrolytic nickel is 5c. per lb. higher.

Gold, Silver and Platinum

NEW YORK—Dec. 15

Gold—The large importations have resulted in some accumulations of gold at the New York Assay Office. The stock of gold bars there is the largest ever held at one time. Most of these bars have been made from English coin. There has been no large arrival of gold this week.

Silver has reacted owing to the satisfaction of the combined Mint and India orders; and though the London stock was somewhat depleted still buyers were satisfied and the market today is quoted dull.

Iridium—This metal is very scarce and in demand. It is difficult to quote, as most sales are a matter of negotiation, price depending upon necessities of buyers. A sale as high as $110 per oz. is reported.

Platinum—Supplies are still scarce and the market is excited and uncertain. Dealers are not willing to make any regular quotations except to customers. Sales are reported at $80@90 per oz. for refined platinum, and there is a prospect of higher prices. Hard metal may be quoted at $90@95 per oz. according to grade.

Zinc and Lead Ore Markets

PLATTEVILLE, WIS.—Dec. 11

The base price paid this week for 60% zinc ore was $85@87. Ore was in little demand, several buyers being entirely out of the open market. The base price paid for 80% lead ore was $70 per ton.

SHIPMENTS WEEK ENDED DEC. 11

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	4,464,000	165,000	1,299,500
Year	199,211,750	6,629,140	28,625,210

Shipped during week to separating plants, 7,144,000 lb. zinc ore.

JOPLIN, MO.—Dec. 11

Blende, high price, $93; base per ton 60% zinc, premium ore, $90; medium, $88@80; lower grades down to $70; calamine base per ton 40% zinc, $65@55; average selling price, all grades of zinc, $84.14 per ton. Lead, high price, $74.75; base per ton 80% metal content, $70@74; average selling price, all grades of lead, $62.92 per ton.

SHIPMENTS WEEK ENDED DEC. 11

	Blende	Calamine	Lead	Values
Totals this week	10,622,760	937,080	2,141,400	$555,780
Totals this year	557,500,380	42,710,730	87,288,100	25,758,550

Blende value, the week, $459,610; 50 weeks, $22,282,110.

Calamine value, the week, $28,770; 50 weeks, $1,126,920.

Lead, value, the week, $67,400; 50 weeks, $2,349,520.

Producers are trying to get together for several weeks' closing down during the holidays. It is not believed any will stop before Dec. 24, but a number will close down on Christmas eve, some for nine days and some for two or three weeks. The time occupied in general repair work, and giving the employees a rest is believed will bring better results later.

The $25 drop of the zinc ore market in two weeks does not look good to producers, and they believe if necessary to restrict the output to steady the market they could find no more opportune time.

The shipment of the week is again short, a drop of 3,370 tons in a fortnight. However, the week-end demand was considerably increased for next week's delivery.

Iron Trade Review

NEW YORK—Dec. 15

December is usually considered a dull month in the iron and steel trades, but this year there seems to be no decrease in activity and no slowing down as the year draws to an end.

Domestic business is increasing in all lines, structural steel being the last to come up. The mills are all full for some time ahead and in certain lines premiums for early delivery are heard of. New business cannot be taken care of promptly, but must wait its turn. This has been rather troublesome in the case of some building contracts.

Export business is again increasing. It is to some extent handicapped by the difficulty of securing freight room, and by the congestion of freight on the railroads running to the Eastern seaboard. In fact freight promises to be rather a troublesome question, as there is already complaint of car shortage. A severe snowstorm in the East this week has served to add to the freight congestion. It is over today, but the storm has been heavy and some days, which can ill be spared, will be needed to put the railroads in good running order again.

The pig-iron market continues strong and advancing. Basic is in a little less demand, but bessemer and foundry are called for in many quarters.

All sorts of reports are current as to new steel consolidations. The latest is that a new concern, to be organized with $250,000,000 capital, has asked for options on the Lackawanna Steel Co., the Youngstown Sheet and Tube Co. and several smaller concerns. The statements made are not fully confirmed. The Republic Iron and Steel Co. is also mentioned in this combination.

Nothing further of a definite nature has been made public as to plans for the future relating to the Cambria and the Pennsylvania Steel companies.

A Washington dispatch says the awards for structural steel required for battleships 43 and 44, to be built at the New York and Mare Island navy yards, have been announced by Secretary Daniels. The awards were as follows: To the Carnegie Steel Co., 51,883,400 lb., $1,686,777; to the Carbon Steel Co., 9,611,720 lb., $537,295; to the Pittsburgh Screw and Bolt Co., 3,593,800 lb., $165,708; to the H. A. Wagner Co., 228,000 lb., $25,365; to the American Steel Foundries 1,836,800 lb., $110,208; total, 67,152,620 lb. at $2,459,354. This material represents the amount needed for both ships.

The United States Steel Corporation reports unfilled orders on its books Nov. 30 at 7,189,489 tons of material. This is an increase of 1,024,037 tons over Oct. 31 and is the heaviest figure reported for many months.

Pig-Iron Production has been almost stationary. The reports of the furnaces, as collected and published by the "Iron Age" show that on Dec. 1 there were 284 coke and anthracite stacks in blast, having a total daily capacity of 103,000 tons; an increase of 1,200 tons over Nov. 1. Making allowance for the charcoal furnaces the total production of pig iron in the United States in November is estimated at 3,368,200 tons; for the 11 months ended Nov. 30 it was 27,036,300 tons. Of this total 19,552,490 tons, or 72.3%, were made by the furnaces owned or operated by the steel companies. The gain in November came from the merchant furnaces.

PITTSBURGH—Dec. 14

Belated buyers, or would-be buyers, of steel products, together with those who have newly arisen wants, have served to keep up the buying pressure in the steel industry at a time when quieter conditions had been expected. The tonnage placed is still fairly large, this being a reflection of the buying pressure rather than of the offerings, for the mills are offering practically nothing and are usually merely yielding to entreaty when they place additional business on books. In the old order of things there would now be active booking of third-quarter contracts, the mills in many branches of the trade being sold up to that time, but the mills will not book open contracts for that period and frequently demur about accepting specific orders for delivery so far ahead.

Inasmuch as so much steel is being consumed in inside work, with comparatively little outside construction going on, the advent of winter is not decreasing the pressure upon mills as it usually does. The weather, however, is beginning to affect production at both furnaces and mills, and the output of the past three months may not be duplicated in the next three.

The Steel Corporation increased its unfilled obligations by 1,024,037 tons during November, recording the second largest increase in its history, as October, 1912, had shown an increase of 1,042,000 tons. That business, however, was largely in open contracts, while the business booked last month, equivalent to almost double the capacity, as the shipments were about 1,200,000 tons, was chiefly in the form of actual shipping orders.

Steel prices continue to rise. The minimum price of 1.70c. on bars, plates and shapes has been entirely withdrawn by some large interests, who quote 1.80c. as minimum, and then only occasionally. Premiums for early shipment are increasing, and plates have sold at 2.50c. for prompt carloads and at 2.35c. for somewhat larger lots for January shipment. Hoops, bars and blue annealed sheets also command premiums for early shipment.

Pig Iron—Pig-iron prices have continued to advance sharply, even though the buying has not been heavy, and there is evidently danger of supplies being insufficient, causing a runaway market. The demand for bessemer lately has been unusually heavy owing to the fact that some of the war steel specifications require acid openhearth steel, and this condition has caused a heavy demand for low-phosphorus scrap. Foundry iron has sold at $18.50, Valley, and even sales at $19 are rumored, presumably under special conditions. Several sales of basic have been made at $18. Alice furnace at Sharpsville had an accident Sunday and a new stack will have to be built, involving at least two months' loss of production. Basic is quotable $1 a ton higher than a week ago and foundry and forge 50c. higher. We quote: Bessemer, $19@20; basic, $18; foundry, $18@18.50; forge, $17.50@18, f.o.b. Valley furnaces, 95c. higher delivered Pittsburgh.

Ferromanganese—There is a good volume of contracting at $100, while odd lots for prompt shipments are bringing that or a trifle more.

Steel—Mills state that billets and sheet bars are fairly quotable at not under $30 for bessemer and $31 for openhearth, f.o.b. maker's mill, Pittsburgh or Youngstown, but these figures represent chiefly the settlement price when consumers adjust extra tonnages with the mills with which they have regular contracts. Possibly a little bessemer could be picked up in the open market but there does not seem to be openhearth at any price. It is expected $34 will be done on bessemer sheet bars for second quarter. Forging billets are about $50 and rods $38 to $40 at mill.

SAULT STE. MARIE CANAL

Freight passing through the Sault Ste. Marie Canal in November was 9,168,431 net tons, an increase of 5,124,063 tons over November, 1914. For the season to Dec. 1 the total tonnage was: East bound, 54,557,241; west bound, 14,552,644; total, 69,109,885 net tons, an increase of 14,291,837 tons over 1914. The number of vessel passages this year was 20,594, showing an average cargo of 3,356 tons. The mineral freights included in the total were, in short tons except salt, which is in barrels:

	1914	1915	Changes	
Anthracite	2,166,555	1,942,630	D.	223,925
Bituminous iron coal	12,191,716	11,092,594	D.	1,099,122
Iron ore	31,413,765	45,138,789	I.	13,725,024
Pig and mfd. iron	237,096	193,352	D.	43,744
Copper	85,038	151,634	I.	66,596
Salt, bbl.	751,618	671,596	D.	80,022

Iron ore this year was 65.3%, and coal 18.9% of the total traffic passing. Of the total freight this year 61,716,005 tons passed through the United States and 7,392,980 tons through the Canadian canal.

FERROALLOYS

Ferrosilicon is in unusual demand and high grade, 50% up to 75%, is hard to get except on contract. Makers have had to refuse several orders for export. The price is now $83@85 per ton at Pittsburgh. Bessemer ferrosilicon has advanced $1 per ton, $30 being asked for 12 to 15%, at furnace. It is understood that plans are taking form for increasing the domestic production of this metal. A new operation at Baltimore is expected to be ready to become a market factor in January and it is understood another furnace is being added at Niagara Falls. The unprecedented demand for 50% and higher ferrosilicon is caused by the heavy orders for ammunition steel which specify a high silicon content.

OTHER ORES

Tungsten ore continues in strong demand and very high prices are reported. It is said that over $50 per unit has been paid for concentrates carrying 65% WO; from the Silver Comet mine in Nevada. The Vasco Mining Co. has been organized by William H. McKenna, of Pittsburgh, to operate a property in Colorado. The concentrate will be made into ferrotungsten at the works of the Vanadium Steel Co. at Latrobe.

IRON ORE

Shipments of Lake Superior iron ore in November were 4,115,129 long tons. For the season to Dec. 1 the shipments by ports were:

	1914	1915	Changes	
Escanaba	3,663,040	5,636,427	I.	1,973,387
Marquette	1,755,726	3,099,589	I.	1,343,863
Ashland	3,363,419	5,196,772	I.	1,833,353
Superior	11,300,748	8,307,381	D.	2,993,367
Duluth	6,318,291	15,457,419	I.	9,139,128
Two Harbors	5,610,262	8,633,980	I.	3,023,718
Total	32,020,486	46,261,568	I.	14,241,082

November shipments did not quite close the season, a few cargoes having been shipped after Dec. 1. The total of these was 57,236 tons, bringing up the shipments to 46,318,804 tons. Rail shipments will make the season total somewhat over 47,000,000 tons.

According to the figures of the Lake Superior Iron Ore Association, Dec. 1, Lake Erie docks held 8,812,499 tons of ore as compared with 8,375,014 tons Dec. 1, 1914, and 9,250,500 Dec. 1, 1913. During the season shipments of ore from Lake Erie docks amounted to 27,027,058 tons as compared with 17,650,073 tons in the season of 1914 and 26,125,758 tons in 1913.

The advance in Lake ore prices has helped to increase Eastern quotations. Some large sales have been made at $4@$4¼c. per unit of iron, delivered, and there is talk of 9c. per unit.

Lake Superior prices, as announced last week are: Old Range bessemer, $4.45; Mesabi bessemer, $4.20; Old Range nonbessemer, $3.70; Mesabi nonbessemer, $3.55; all f.o.b. Lake Erie ports. The base remains unchanged at 55% iron and under 0.40 phosphorus for bessemers; 51.5% iron for nonbessemers.

COKE

Coke production in the Connellsville region for the week is reported by the "Courier" at 437,251 short tons; shipments, 439,165 tons. Shipments of Greensburg and upper Connellsville districts, 44,859 tons. There is much complaint of labor shortage.

Anthracite Shipments in November were 6,297,215 long tons, an increase of 368,929 tons over November, 1914. For the 11 months ended Nov. 30 the total shipments were 62,640,373 tons in 1914, and 60,182,218 in 1915; a decrease of 2,488,155 tons, or 3.9% this year.

Chemicals

NEW YORK—Dec. 15

The market is showing a steady tendency and the general undertone seems to be good.

Arsenic—Business is moderate, but generally steady. Prices are about the same, $3.75@4 per 100 lb. being quoted.

Copper Sulphate—Stocks are rather low. Business has been good. Quotations are $10 per 100 lb. for carload lots and $10.25 per 100 lb. for smaller parcels.

Nitrate of Soda—This article continues strong, slow deliveries and high ocean freights helping to keep up prices. Spot is held at $3.15@3.25 per 100 lb., while $3.15 is named for December and January, and $3@3.10 for later deliveries.

Imports and Exports of Raw Materials for chemical manufacture in the United States nine months ended Sept. 30, in long tons:

	Imports		Exports	
	1914	1915	1914	1915
Sulphur	15,036	17,869	96,624	16,248
Pyrites	776,871	675,106		159
Chrome ore	56,081	38,649		
Magnesite	92,925	20,144	1,196	414

Exports include reëxports of foreign material. Estimating sulphur contents of pyrites the total imports of sulphur this year were 287,900 tons.

PETROLEUM

The monthly statement of the "Oil City Derrick" shows new wells completed in November as follows: Pennsylvania grade, 466; Lima-Indiana, 62; Central Ohio, 106; Kentucky, 12; Illinois, 84; Kansas, 206; Oklahoma-Arkansas, 709; Texas Panhandle, 38; North Louisiana, 11; Gulf Coast, 89. This is a total of 1,813 wells, having an aggregate daily production of 174,697 bbl. There were 216 gas wells and 293 dry holes. There were 2,594 new wells being drilled at the close of the month.

Another advance in crude oil has brought Pennsylvania grade up to $2.10 per bbl., an advance of 75c. since last January.

Exports of mineral oils from the United States in October are reported by the Department of Commerce at 204,607,069 gal. For the 10 months ended Oct. 31 the exports were 1,889,556,766 gal. in 1914, and 1,938,230,760 in 1915; an increase of 48,673,994 gal., or 2.6%, this year.

Stock Quotations

Stocks generally declined during the last week with recoveries Monday and Tuesday. Alaska Gold went to a low of 21⅝. Thomas W. Lawson is effervescing today (Dec. 15) with predictions of a "terrific copper boom in January," and the prudent ones will probably shortly take to tall timber.

VOLUME 100 DECEMBER 25, 1915 NUMBER 26

Gas-Fired Reverberatory Furnace at Sulitjelma, Norway

By C. Offerhaus*

SYNOPSIS—At Sulitjelma, Norway, the concentrates from the Elmore vacuum oil-flotation process are roasted in an 8-hearth Wedge furnace and smelted in a gas-fired reverberatory furnace having a regenerator for preheating the combustion air. A strongly basic slag is made; magnesite brick and water-cooling pipes are used in the back part of the furnace.

The tailings of the wet concentrator at Sulitjelma, Norway, containing 1% to 1.6% Cu, have been successfully treated for a number of years by the Elmore vacuum oil-flotation process. Over 80% of the copper content of the mill tailings is saved in the Elmore concentrates, which contain 5.8% to 6.8% Cu, the Elmore tailings carrying from 0.13% to 0.25% Cu. The oil consumption is about 2 liters per 1.2 tons of mill tailings. Addition of acid is not made here, as it proved unnecessary. The following are average figures covering six months' operation of the Elmore plant: Wet-concentrator tailings, 1.11% Cu; Elmore tailings, 0.23% Cu; Elmore concentrates, 6.78% Cu. An average analysis of the Elmore concentrates is as follows: Cu, 6.5%; S, 35.3; Fe, 36.8; SiO_2, 12.7; Al_2O_3, 4.83; CaO, trace; MgO, 0.72%. The oil sticks to the concentrates, and this has a marked hindering influence on the further treatment of this material.

Formerly these concentrates were made into briquettes, first with an addition of about 4% of lime, and later with 0.2% of NaCl, added in solution. They were then dried and together with coarse ore were smelted in Knudsen converters. However, the concentrates accumulated and in the autumn of 1911 the Sulitjelma Aktiebolaget decided to build a plant consisting of a Wedge roasting furnace and a reverberatory matting furnace to treat 70 to 90 tons of concentrates daily. As is well known, the coarse ore is smelted at Sulitjelma by the Knudsen process.[1] The melted contents of a converter after a blow are poured into a small gas-fired reverberatory furnace—regenerative system—that serves only as a settler to separate the slag and matte; the slag containing 2.5% Cu is lowered to 0.5% to 0.6% Cu by this treatment. Most of the time, from lack of coarse ore, only one of the 15-ton converters is in operation, and in this case it does not pay to run the gas-fired settler. The contents of the converter are poured on the floor, broken up as soon as cold and smelted once more in a small water-jacketed furnace having a diameter of 1 m. at the tuyeres. The reverberatory furnace of the new plant should serve also as a settler for the molten contents of the converter, thereby eliminating the resmelting. The new plant was finished during the summer of 1912 and has been in operation since that time.

SULITJELMA SMELTING PLANT IN NORTHERN NORWAY

Oily Concentrates Difficult to Roast

The roasting plant consists of one large modern Wedge roaster with 8 hearths (the drying top hearth included)—a total hearth area of 175 sq.m.—water-cooled shaft and rabble arms. This furnace is so well known that a detailed description is not necessary. It was guaranteed to roast 80 tons of Elmore concentrates containing about 35% S down to 8% S in 24 hr. However, this capacity was never reached. The highest reached, after doubling the number of revolutions, was 60 tons of Elmore concentrates, including 10% of ground quartz,

*Metallurgical engineer, Siemens Copper Co., Artvin, Caucasus, Russia, or care of J. van't Hof, Sloterdyk, via Amsterdam, Holland.

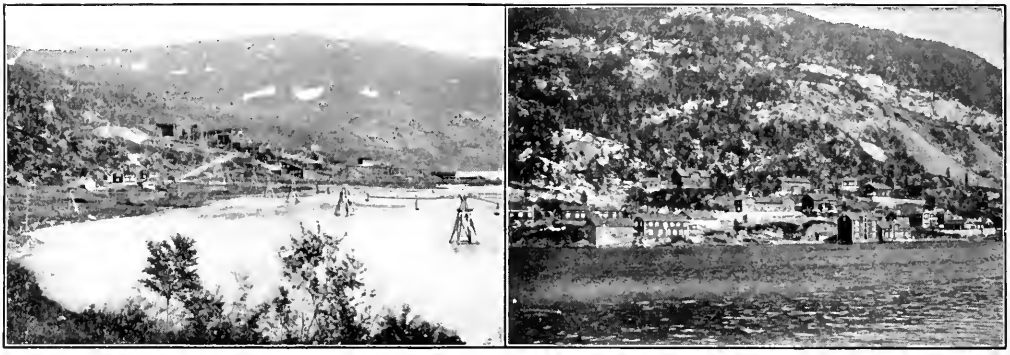
[1]Chem. Ztg., 1909, No. 38; "The Mineral Industry," Vol. XVII, p. 315.

and the average daily treatment during nine months was 47 tons, including 10% of quartz, which was roasted down from 30.72% to 8.12% S. These figures tend to show that Elmore concentrates do not roast easily, and the explanation therefor is the oil film which covers each grain of ore, making it difficult to ignite. It might be mentioned in passing that it is also difficult to sinter this material, probably for the same reason, and pot roasting does not give satisfactory results at all. The Dwight-Lloyd machine showed a smaller capacity than was expected and gave about 15% fines, which had to be recharged.

The wet Elmore concentrates are weighed, then fed into a rotary drier, through which the hot gases of the roasting furnace pass in the opposite direction. The concentrates are discharged into the buckets of an elevator, which delivers them to the upper drying hearth of the Wedge roaster. The calcines drop into two stone bunkers situated under the furnace floor and are discharged through gates into steel cars having a capacity of about ½ ton of roasted material. The cars are taken up by a lift to the level of the reverberatory-furnace charging floor and thence trammed to the charging hoppers.

The reverberatory furnace was in principle built after the type of the Anaconda furnaces, but recovery of the waste heat of the furnace gases in generating steam was not desired, as the company has very cheap water power (1 hp.-yr. costs at Sulitjelma, interest on the initial cost of the power plant included, 15 kr., about $1.20) and does not have any use for steam. The heat of waste gases is utilized in preheating the combustion air. The new reverberatory furnace is gas-fired, of the regenerative type, with Weardale burners; overall, it is 24 m. long and 6 m. wide. An accompanying drawing shows the reverberatory plant, with gas producers, furnace and regenerator in longitudinal and cross sections and presents the main dimensions of the furnace. The gas producers *A* are of the Schmidt & Desgraz type, with circular nonmovable grate, water-sealed; the diameter of the shaft is 2½ m. They are worked with pressure air from the fan *B* and steam from a small boiler *C*. These producers can gasify 8 to 10 tons of English coal (Hamilton double nut) and give, if not forced, a good hot gas, low in carbonic acid.

The gases of the three producers come together in a main flue *D* and are divided by both gas valves *E* over the roof and back-wall tuyeres. The combustion air comes from a low-pressure ventilator *F* and is divided over the regenerator and the double roof, as shown in the drawing. Part of the air is preheated in the regenerator, passing through vertical tubes of refractory material built in groups of seven and going back through the channel *G* to the back part of the furnace. Another part of the combustion air is preheated in the double walls of the channel connecting the furnace with the regenerator, and also in the double roof of the furnace. By means of two sliding valves *H* it is possible to make a connection between the preheated air in the regenerator and that of the double roof. The combustion gases pass to the front of the furnace, ascend, and then go down through the downtake and the submerged channel *I* to the regenerator. At *J* there are dampers which divide the combustion gases over the proper regenerator and the direct channel *K*. In the regenerator the gases pass on the outside of the tubes. At *L* the combustion gases come together and go to the chimney *M* (artificial-suction arrangement). The producer-gas channels and regenerator are built of "chamotte" brick; those parts of the furnace exposed to high temperatures, for example, side walls and roof, are of silica brick. Silica bricks from Höganäs, Sweden, have given full satisfaction. They are very refractory, do not expand much, are straight and can be cut well. The upper roof is built of third-quality chamotte brick, which do not cost any more than red brick in Sulitjelma. The upper roof is, as will be seen by the drawing, independent of the lower roof, which construction proved satisfactory. The crossbeams in the upper roof bent somewhat from the heat, and in cases of wide furnaces the I-beams should be connected with second ones laid over the top, which will not suffer from the heat, as they would be air-cooled. A larger I-beam would answer the same purpose.



TWO VIEWS OF SULITJELMA COMPANY'S PROPERTIES IN NORTHERN NORWAY

The view at the right shows the gravity concentrator and the Elmore vacuum oil-flotation plant at Sandtnes. At the left, miscellaneous company buildings at Furuland

Basic Lining and Water Cooling Employed to Resist Basic Slag in Hottest Part of Furnace

As stated before, the Elmore concentrates contain an average of 12.7% SiO_2. The company does not possess a siliceous material that contains copper, and quartz flux must be brought from a long distance. Therefore

it is necessary to make a slag that is low in silica and high in iron, some slags being as low as 28% and 30% SiO_2. The back and side walls of the furnace up to the fourth door were built of magnesite brick to the level of the bath; as this material does not resist a strongly basic slag at high temperature, the magnesite lining up to the fourth door is water-cooled by a series of pipes, laid in the brickwork.

A detailed drawing shows the cooling pipes assembled, and the general plan of their position in the furnace. The pipes are seamless tubes with an inside diameter of 56 mm., the thickness of the walls being 10 mm. The cast-iron covers consist of two pieces with a planed channel in which the tube fits tightly. They serve to increase the cooling surface, to facilitate the laying of the brick and to protect the tubes. This construction is better and more convenient than iron cast around the pipes, as is generally done.

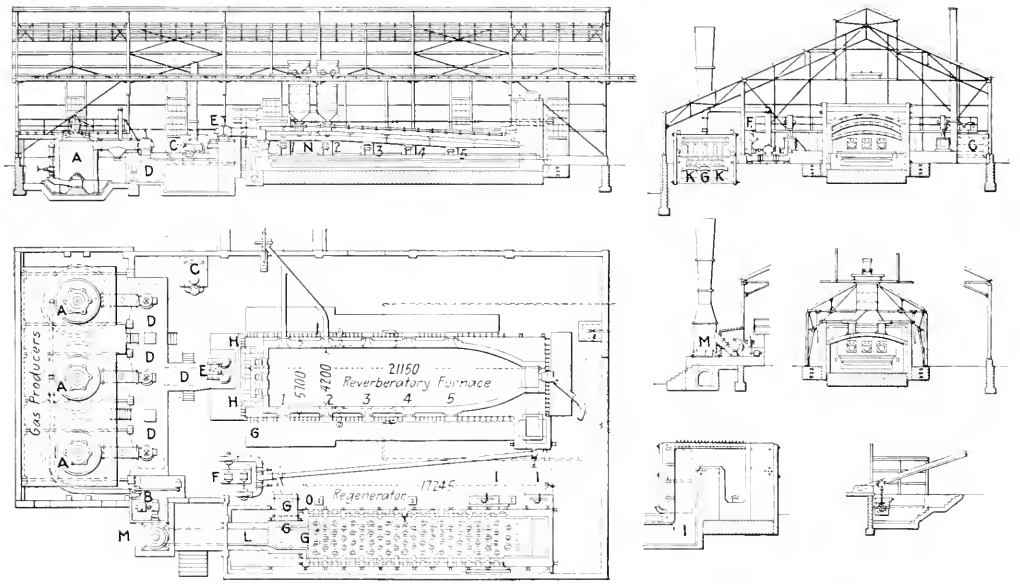
A layer about 300 mm. in thickness, consisting of six parts of ground magnesite brick (5 mm.) and one part of granulated slag, both by volume, is used in the back part of the hearth. This mixture is put in slightly moist and tamped with hot iron tamping bars. This bottom has given satisfaction. The hearth is not attacked by the bath of matte. However, a charge that is being dropped may not spread over the surface of the bath, but sink to the bottom.

The writer therefore recommends that at least the back of the hearth be lined with magnesite, when working with a strongly basic slag. The front of the furnace, the hearth and the side walls, up to the fourth door, may be built of any kind of refractory material, as the slag of a temperature that exists here will hardly attack the brickwork under any normal conditions of operation.

The charging hoppers through the roof of the furnace are iron castings and are lined with magnesite brick. The silica brick near the charging holes are eaten away by the slag formed by dust that strikes the walls when dropping a charge. For this reason it is considered advisable to transfer the charging hoppers to the crown of the arch. The tapholes are under the second and third doors from the back.

The regenerator is of the tube type, with vertical tubes of chamotte; it is so built that it cannot become stopped up, and this was only possible at the expense of its efficiency and dense construction. The regenerator also serves as a dust chamber and is provided with doors on both sides for removal of the flue dust. A dense regenerator with large surface to interchange the heat could not be built in this case, as the narrow passages would soon become clogged with flue dust.

The three gas producers gasify 5 tons of coal each in 24 hr. As previously stated, one producer is able to gasify 8 to 10 tons of English coal. Therefore it is possible to run the furnace with two producers, having one in reserve. However, it is preferred to run them all, as it is easier to make a gas of good quality if not forced too much. Under these conditions the producer gas contains 2% to 4% CO_2, and an average temperature of 500° C. at the furnace valves *E*. The temperature of the preheated air from the regenerator taken at *G* is 500° to 550° C., and that of the air preheated in the double roof at *N* is 420° C. The furnace temperature taken at the first door from the back is about 1,500° C., at the fifth door 1,275° to 1,300° C. and at the skimming door 1,200° C. The combustion gases enter the regenerator with a temperature of 1,000° to 1,100° taken at damper *J* and leave at about 390° C.



REVERBERATORY SMELTING PLANT OF SULITJELMA AKTIEBOLAGET IN NORTHERN NORWAY

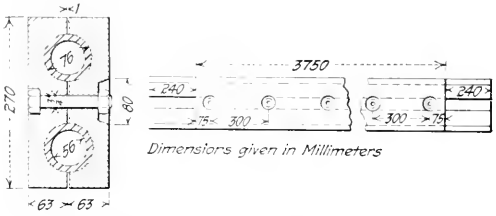
The reverberatory furnace is fired with gas from Schmidt & Desgraz producers and the waste heat of the furnace gases is utilized to preheat the combustion air. The back and side walls of the furnace are lined with magnesite brick up to the level of the bath and are further protected by water cooling

The loss of heat caused by the water cooling of the fire bridge and side walls is about 2,500 Cal. per min., corresponding with about 3% of the coal consumption.

The charging of the furnace is done below with lever arrangement. The chamotte plate which covers the charging hole is pushed back, the sliding valve of the hopper is opened and the hot charge drops into the furnace. Two charges of 1½ ton each are alternately charged from two hoppers, and as soon as the 1-ton charge is smelted, the next one follows. Attention may be called to the fact that the roasting furnace does not keep pace with the smelting furnace, and the latter is always waiting for its charge.

Composition of the Sulitjelma Slag

As mentioned before, conditions at Sulitjelma make it necessary to make a slag as basic as possible. The average composition of a normal reverberatory-furnace slag is as follows: SiO_2, 32.5%; FeO, 51.5; Al_2O_3, 10.8; CaO, 1.1; MgO, 2.1; S, 2; Cu, 0.5%. The average SiO_2 and Cu covering a period of nine months was 32.6% SiO_2 and 0.55% Cu, the matte averaging 36.3% Cu. The copper content of the slag goes down occasionally to 0.45% Cu and lower. The high average copper content of the slag, considering the grade of matte,



ARRANGEMENT OF WATER PIPES FOR COOLING REVERBERATORY-FURNACE WALLS

is due to its high specific gravity and also to the fact that sometimes a thick slag with a high formation temperature is made, which tends to keep the matte suspended. The formation of this thick slag is caused by the fluctuating sulphur contents of the charge, which can hardly be avoided if running only one roasting furnace. If the roasted ore contains a small amount of sulphur, the constant amount of silica flux is not sufficient to make a slag of the desired composition. A matte rich in copper and a slag low in silica and high in iron are formed—the so-called thick slag, which forms a third layer between normal slag and matte. The following is an analysis of such a slag: SiO_2 16.1%; FeO, 50.6; Fe_2O_3, 16.2; Al_2O_3, 10.1; CaO, 0.70; S, 1.5; Cu, 4%.

The reverberatory furnace is skimmed once every eight hours. The clay wall built in the slag door is partly cut away, and the slag flows to a cast-iron settling pot through a cast-iron launder bent at an angle of 90° and leading to an opening in the floor. The first straight piece of this launder is provided with a rectangular hole, through which the slag drops into a stream of granulating water from a 6-in. pipe slightly flattened at the end. The granulated slag is then carried to the sea through a launder built of masonry and lined on the bottom with old crusher jaw plates. The hole in the launder lets just as much slag through as can be taken care of by the water, and if for any reason there is an excess of slag that cannot be stopped, it flows through the bent launder to the opening in the floor at the side of the granulating launder. As a safeguard in case of explosions or stopping up of the granulating launder, which runs partly underground, a brick is cut to fit the opening in the slag launder. This can be readily placed or removed as desired.

Frozen Tapholes Opened by Oxygen Method

Matte is tapped as wanted by the converter plant, or if too much accumulates in the furnace it is tapped, through sheet-iron launders lined with brick, into a 2-ton ladle suspended by means of a carriage on a sloping rail; the ladle is pulled to the old converter building and poured at once into a small converter. If by carelessness of the furnacemen the taphole freezes so that a bar cannot be driven, it is not drilled as usual, but opened in the following manner:

An iron tube 3 or 4 m. in length, with an inside diameter of about 10 mm. and walls of 3 mm. thickness, is connected at one end, by means of a rubber pressure tube, to an oxygen flask. The other end is heated to redness by inserting it in the furnace door. The red-hot end is then inserted in the tapping hole, the reduction valve of the oxygen flask opened and oxygen introduced at a pressure of about 6 atmospheres. By the rapid burning of the iron tube in oxygen, there is generated so much heat that the taphole is burned through in a short time. This method is of especial value if a tapping bar has been broken off in the hole, and it is much quicker than drilling—even with a machine drill.

It is an advantage under the present conditions at Sulitjelma to make a matte in the reverberatory of not too high a concentration; for example, about 35% Cu. In doing so less strain is put on the roasting furnace, which is able to handle more concentrates. The grade of the matte is increased from time to time to 40% or 45% by the molten contents of the Knudsen converters (about 50 tons of matte and slag daily), which are dumped into the reverberatory furnace. The matte made in the Knudsen converters contains 50% to 55% Cu and sometimes more—if crusts are formed in the converter and it becomes necessary to run the charge longer than usual in order to melt the crusts down. The converters have a basic or neutral lining, so converting a 35% matte has no disadvantage. The Knudsen converters at Sulitjelma have been basic-lined for over seven years, and the ordinary small converters of 1 and 1½ ton capacity, for several years. However, only the bottoms of the small converters are lined with magnesite brick, the walls being lined with ordinary neutral refractory brick.

The average charge of the roasting furnace during a long period was 47 tons of concentrates, corresponding to 40 tons of calcines. As it is not possible to give the reverberatory furnace all the charge it can handle, it has, of course, a bad effect on the amount of coal used. With the same amount of coal and a hot charge, it is possible to smelt 70 tons of ore, and in this case the coal consumption would be 23%.

The back and side walls of the hottest part of the furnace need repairing every four weeks. Matte is accumulated in the furnace, and as much of the slag as possible is tapped out. Then almost all of the matte is

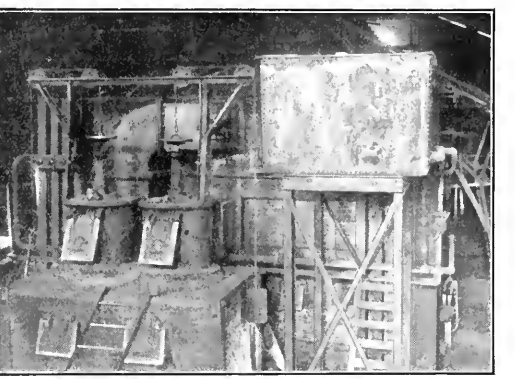
also tapped out. The gas is shut off, and the magnesite mixture already mentioned is thrown against the walls of the almost dry furnace. Advantage is taken of this opportunity to burn the soot out of the gas flues. The gas flues must be cleaned every fortnight, and this means loss of smelting time, as the gas must be cut off for about five hours and the furnace loses a great deal of its heat. The gasways in the furnace itself must be cleaned once a week. They can be cleaned one at a time without shutting off the gas.

The flue dust forms a loose deposit on and between the tubes of the regenerator—most of it in the front part near the damper—and must be cleaned out every two or three weeks. No trouble is experienced in taking out the dust from the doors at each side of the regenerator, this being done without interfering with the running of the furnace.

Before closing I should like to make a few general remarks concerning the heating of reverberatory furnaces for smelting concentrates. The chief duty of the reverberatory furnace is to melt down a charge prepared beforehand. It is confirmed by experience that the number of charges that can be made in a certain period of time will rapidly increase with the temperature of the furnace. It follows that such a furnace in which it will be possible to attain the highest temperature will work the most economically. The combustion gases must leave the furnace with temperatures no less than 1,100° to 1,200° C. Up to the present the most efficient way to recover the heat of these gases is in generating steam, and where it is profitable to use steam it is advisable to heat the furnace with semi-gas, oil or coal dust. Semi-gas and oil have been used a long time and are known to work satisfactorily. Coal dust up to the present time is only used in a few places and has been reported a success. It is certainly suitable for reverberatory furnaces, and probably even better than semi-gas. Gas firing can be economical only when there is no use for steam.

In case of gas firing, the ordinary regenerators to preheat the air, built with large surfaces to interchange the heat and of dense construction, cannot be used, as they would soon become stopped up with flue dust. The regenerators must serve also as dust chambers. Regenerative furnaces with large and long chambers without filling material have been used and are reported to have given satisfaction. However, the first cost is considerable, and they occupy a great deal of space.

TAPPING MATTE FROM GAS-FIRED FURNACE



GAS VALVES AT BACK OF SULITJELMA FURNACE

Mexican Mining Taxes

Some of the larger mining operators in Mexico recently transmitted to General Carranza a petition with regard to the excessive taxation that is imposed upon the Mexican mining industry by his recent decrees covering the yearly pertenencia tax and the tax on metal exports. The original English version of this petition, which was translated into Spanish for delivery to General Carranza is as follows:

To His Excellency, Venustiano Carranza
Chief Executive of the Republic of Mexico:

Your petitioners have the honor most respectfully to lay before you the following considerations:

1. Your petitioners represent many of the more important American and foreign-owned mining undertakings in Mexico, both the larger and the smaller. Their interests, however, are identical with the interests of those mining undertakings which are Mexican-owned, and their present plea is in behalf of the mining industry in Mexico as a whole, whether the ownership is native or foreign. They seek no privileges, no exemptions, no preferences. The treatment they hope for, and here petition for, is such treatment only as shall be applicable to all persons or companies alike, who are similarly situated, large and small, Mexican and non-Mexican.

2. The mineral industry in Mexico at the present time is virtually dead. Not more than 3% of the mines are operating. Mines are flooded and caved in. Plants are damaged and destroyed. Machinery and equipment are injured or wrecked. Materials and supplies are exhausted. Operating forces are scattered and demoralized. Necessary means of transportation are either wholly lacking or obtainable with the greatest difficulty and in insufficient amount. This vital need will not adequately be supplied until after the lapse of years. To resurrect the industry will be nearly equivalent to establishing it anew.

3. The investments already made in the mineral industry of Mexico run into many millions of dollars. Again to place the industry on a successful operating and producing basis, these investments must be greatly increased, and very large amounts of additional capital must be expended. Further, all expenses of operation will be enormously increased, particularly in respect to the matter of securing facilities of transportation and of procuring necessary materials and supplies.

4. To the extraordinary costs and disbursements thus involved in a restoration of the industry must be added the very heavy losses, both direct and indirect, which those concerned in the industry have had to bear throughout the

revolutionary period, now in its fifth year. Aside from the wiping out of profits, these losses have resulted from damages to mills, smelteries and surface equipment, caused by revolutionary forces as well as by lawless bands, from the flooding of mines with water through the enforced stoppage of pumping operations because of the lack of fuel and otherwise, from the seizure of animals, supplies, provisions and many other goods, and from the maintenance of unprofitable operations, and the direct importations of food and provisions in order to supply the necessities of life to employes or their families.

5. These burdens are necessary and unavoidable, the hard facts of the situation being as they are; and your petitioners realize that nothing can lighten the load of expense which must inevitably be borne, if they are to save the investments they have already made and if the future, however remote, is to yield them a return. But there is an added burden threatened, which is neither necessary nor unavoidable, nor the inevitable consequence of existing conditions, and which may easily prevent a revival of the industry. This is a burden which it is within your power either to lift or to impose. It is the burden of greatly increased taxes upon an industry already taxed in heavy measure; the burden, in other words, imposed by your Decree of Mar. 1, 1915, as modified by your Decree of Aug. 31, 1915.

6. In asking you to remove this added burden, your petitioners would have you consider not only the relief thereby afforded to private interests, but the public benefits which must accrue to the Mexican people living in the numerous communities which are dependent upon the mining industry for a livelihood or engaged in the many commercial pursuits to which the mining industry gives rise, through the rebuilding of a great industry now prostrate and helpless. Interests of necessity obliged, if they proceed, to expend vast sums of money in a country ravaged by years of civil war, furnishing employment and means of subsistence to thousands of persons to whom no other occupation is open, creating wealth and prosperity to the certain benefit of the state and the body politic, in localities where there is now only poverty and distress, requiring the rehabilitation of the railroads and thus furthering the welfare of the whole people, increasing the imports and exports of the country, and generally promoting the commerce of the land, both domestic and foreign—and doing all this at their own risk and cost and in the face of enormous difficulties—should not, it is respectfully submitted, be discouraged, and not only discouraged, but in many cases dissuaded from remaining in the field, by the imposition of exorbitant taxes.

7. Your petitioners submit and earnestly maintain that the taxes laid upon the mineral industry of Mexico under the Constitutional laws of the Republic, prior to the issuance of your decree above mentioned, are already so high that to raise them would be unjust and harmful to the industry. Such taxes, however, have been fixed by law, and your petitioners accept them as among the necessary charges inevitably to be met. They do not seek to escape them. They are prepared to pay them, as they have paid them heretofore. And they make no protest against paying them in gold. They readily concede that the Mexican government is entitled to receive its lawful due in full, and without deduction by reason of depreciated currency or otherwise. Their protest is directed solely against the multiplication of such taxes, especially at a time when the industry is struggling for its life and before it can be known whether it is to survive or perish.

8. The established pertenencia tax of 6 pesos per pertenencia up to 25, and 3 pesos per pertenencia on all over 25, is an equitable tax, considered in relation to the subject matter; and as one item in a series or group of taxes to which mine-owners are subjected, and since it is to be paid in gold, it should be highly satisfactory to the state as a source of revenue. At the same time it is not unduly burdensome on the taxpayer. At least the taxpayer has adjusted himself to it and is prepared to meet it. Moreover, it is graded in accordance with sound economic policy, inasmuch as the rate is reduced one-half on all pertenencias over the minimum of 25. Under your decree this policy is reversed, and the rate is progressively and rapidly raised as the number of pertenencias increases above the lower minimum of 10. In addition, the tax per pertenencia for those included in the reduced minimum is doubled. To enforce the new taxes decreed would be oppressive and, it is feared, in many cases confiscatory. In the development of mining enterprises along the best lines, the control of large areas is imperative. But the development must proceed gradually. Both the initial and the ensuing costs are great. The larger part of the territory must remain unworked for years, awaiting the growth of the enterprise. But with the first establishment of the enterprise, new industries, new communities and new source of wealth are created. In the meantime the mine owner must carry the pertenencia tax, yearly, on all his claims, developed or undeveloped, productive or nonproductive, operated or not operated. Furthermore, to increase these taxes would be to tax mineral holdings out of all proportion to the taxation on other lands and real estate in Mexico. It would probably discourage small companies and individuals from holding property which might be worked some day when affiairs have been reëstablished on a normal basis in Mexico. Property so released would fail to bring revenue to the Mexican government unless large and wealthy corporations could afford to redenounce them and hold them until normal conditions were again established. The result would be to discourage the companies or individuals with limited resources. It should be remembered, moreover, that the areas held in reserve, on which the tax is nevertheless regularly to be paid, in practically all cases are of low-grade character, unsuited for ordinary development and unworkable except in connection with operations on a large scale, conducted on a systematic plan involving much time and steady outlay.

9. The established export taxes on gold and silver in bullion of 2½% and on gold and silver ores of 3½% are neither light nor easy to bear, but neither are they unreasonable. They are, however, it is confidently believed, as much as the metal industry can stand, in connection with other taxes, with a view to the yield of the maximum revenue to the state from this source. The gross value of metals out of which such taxes must be taken for a long time to come must also be charged with greatly increased cost of production, to say nothing of the added interest on new capital invested. Under your decree the export tax on silver and gold would amount to approximately 6½% when contained in bullion and approximately 8¼% when contained in ores. It is firmly believed that these increased taxes would prove so excessive and so burdensome, particularly on low-grade mines, as to make it inadvisable to attempt operation under them with any hope of profit. It is believed that the new taxes on copper and lead would result in a large curtailment of production, because nearly all of the old high-grade lead-producing mines in Mexico have been exhausted and the present source of lead in Mexico is the low-grade lead mine developed and equipped at a large expense and operated upon a particularly low margin of profit. The character of the copper production in Mexico is much the same as that of the lead. Mexico has but a few copper mines. These are very low-grade and in the aggregate have yielded but a small return of profit to their owners. Clearly, it is to the best interests of the Republic of Mexico, as well as to the mineral industry at large, for the government to encourage and assist the lead and copper producers as much as possible in order to stimulate prospecting and developing of mines of this character. The basis of the entire smelting industry rests upon the lead and copper production of the country. An adequate supply of these two metals insures the development of all classes of mines and thereby brings correspondingly increased revenue to the government. The imposition of such heavy taxes as have been proposed on these two metals will result in the strangulation of a large portion of the mineral industry of Mexico.

10. Finally it is submitted, that if the new and increased taxes here complained of are removed and if some assurance is given that federal, state and municipal taxes on mineral property and mineral production and operation will be allowed to rest on the basis of the laws existing from 1905 to 1910 and if the coöperation of the government can be had in facilitating the importation and reasonable dispatch in transportation and delivery of coal, coke and fuel oil to the various mines and plants, and of dynamite, cyanide and other materials most urgently required by the industry, without additional import taxation, your petitioners and all those in a like situation with reference to Mexican mining operations will be given that encouragement which they sorely need in assuming the heavy undertaking before them of reviving the mineral industry in Mexico; and they confidently predict that such encouragement will result in the earliest possible restoration of the industry in all its branches, with steadily increasing revenue and prestige to the Mexican government; otherwise, they must be greatly discouraged and seriously hindered, if not altogether checked, in going forward with their undertakings.

For the foregoing reasons your petitioners most earnestly appeal to you to abrogate the Decrees of Mar. 1, 1915, and Aug. 31, 1915.

This is one of several strong memoranda which have been drawn by organizations of the Mexican mining people in the United States and in Mexico in an endeavor to obtain modification of the excessive taxation that has been heaped on the mining industry.

Development of Dredging in Yukon Territory*

SYNOPSIS—Dredging in the Yukon began on Lewes River in 1899 with 3½-cu.ft. buckets; today dredges with 16-cu.ft. buckets are operating in the Klondike River valley. Steam thawing of frozen ground was one of the important developments in the Northern dredging field, having greatly extended the dredgeable area and reduced the wear on the dredges. Conditions are extremely variable and heavy equipment is the rule. Operating costs of the Yukon Gold Co. for the last six years are given.

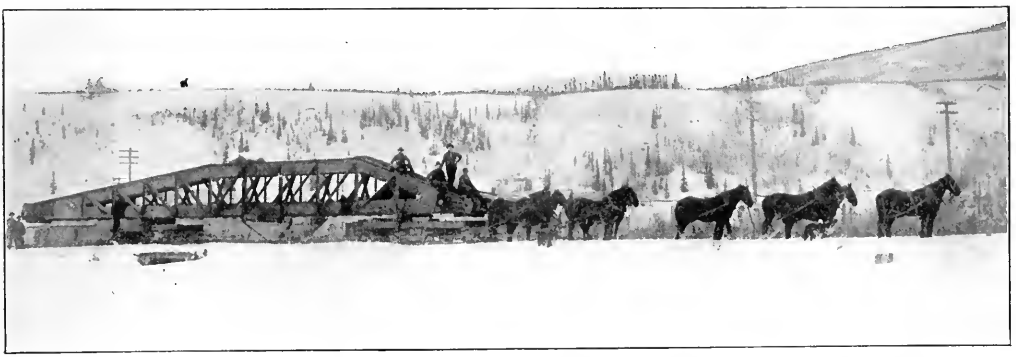
The first dredge in the Yukon was a small, 3¼-cu.ft. bucket, New Zealand-type dredge built on Lewes River in 1899. In 1901 it was moved and rebuilt on No. 12 Below on Bonanza Creek, and in 1903 moved to the Discovery group. This dredge, which was practically obsolete by 1905 and entirely unsuited for the work, proved the practicability of dredging on the Klondike creeks. The next dredge to be built was the Canadian-Klondyke No. 1, a 7-cu.ft. dredge which began operation in August, 1905, in the valley of the Klondike River, opposite the mouth of Bear Creek. These two dredges may be said to have shown the way to the large development which followed.[1]

The first three dredges of the Yukon Gold Co. were built on Bonanza Creek in 1906 and began operation early in 1907. These were followed in 1907 and 1908 by four 7-cu.ft. bucket dredges, two on Bonanza and two on Hunker Creek. In 1910 the Canadian-Klondyke Mining Co. built the first of its 16-cu.ft. dredges, which began operation in November of that year. In 1911 the Yukon Gold Co. built two all-steel dredges, each having 7-cu.ft. buckets. The Canadian-Klondyke company in 1913 built Nos. 3 and 4, both 16-cu.ft. machines. This comprises the dredging equipment now in use in the Klondike field. In 1907 two Risdon dredges were built on Walker's Fork, one of which was later moved to Miller Creek, where it is now operating, and a dredge was installed on the Bonanza Basin which has since been abandoned.

Electric Power Essential to Economical Operation

In order to operate successfully, and within the limit of expense, electric power was a necessary adjunct to the dredging. In 1906 the Yukon Gold Co. installed a 2,000-kw. hydro-electric plant at the junction of the Twelve Mile and Little Twelve Mile Rivers, 32 mi. from Dawson. The Granville Power Co. followed four years later with a plant on the north fork of the Klondike River. The Canadian-Klondyke company takes its power from this plant.

In terms of investment, the Yukon Gold Co.'s first seven dredges cost $1,000,000. The power plant cost $550,000 and the two all-steel dredges $500,000 more, making a total investment in dredging equipment alone of over $2,000,000. The three large dredges of the Canadian-Klondyke company are estimated to have cost $475,000 each. The power plant of the Granville Power Co. cost over $1,000,000. These figures do not take into account investment in shops, buildings, and accessory plant.



HAULING THE DIGGING LADDER OF DREDGE NO. 5 OVER A WINTER ROAD IN THE YUKON

In order to make a success of a dredging enterprise so far from the source of supply, the equipment must be complete and of the best possible kind. A single breakdown or loss of a part which could not be replaced might mean the loss of a season's work, so that the supply of extra parts and the shop equipment for repairs is much greater than ordinarily required.

Generally speaking, the dredging equipment does not differ greatly from the equipment in use in California. The machines follow the lines of the dredges developed in California, but, in the building, were increased in strength of parts over anything of the size previously built. The service is extremely severe and the season short, so that all digging and working parts subjected to strain are reinforced and made heavier than is usual in dredging practice. The best of material is used; all important shafting is of nickel steel, the buckets are of chrome-nickel

*A paper presented by O. B. Perry at the seventeenth annual meeting of the Canadian Mining Institute, Toronto, Ont. This will be printed in the annual volume, prior publication being granted the "Journal" by courtesy of the Institute Council.

[1]T. A. Rickard, "Min. and Sci. Press," Aug. 12, 1908.

steel or of manganese steel; the pins are of high-carbon steel, nickel steel or chrome-nickel. The tendency has been to increase continually the strength, and, therefore, the weight of the principal parts. The last two dredges built by the Yukon Gold Co. of all-steel construction are 20% heavier than anything of the size in use at present.

Two Classes of Gravels Dredged

Dredging in the Yukon is now being conducted on two classes of deposits, river valley and creek beds. The deposit in the valley of the Klondike River is, where thawed, well adapted for dredging. The material is free wash gravel, rounded and clean, averaging from 30 to 40 ft. in depth. The bedrock is sufficiently decomposed to be dug with ease. The top burden, in the thawed portion of the deposit, has been largely removed by stream action and presents little or no difficulty to dredging.

The creek deposits present altogether different characteristics. The deposits are shallow, for the most part ranging about 18 to 20 ft. to bedrock. The gravel is angular and contains little sand. The gold is confined almost entirely to bedrock. The creek gravels are overlain by a deposit known locally as "muck," which is made up of organic matter, fine sand and water, almost invariably frozen, and, where undisturbed, covered with a blanket of moss. The depth of the covering of muck is from 4 to 8 ft., with an average of about 6 ft. In the dredging operation on the creeks it is necessary to take up from 4 to 6 ft. of the bedrock itself, which is a sericite schist and usually massive and blocky in character.

Operations in the Yukon district are subject to difficulties which are not met elsewhere, except in Alaska. These may be described under two heads: (1) Climatic; (2) character of deposits.

The extreme cold of the Northern winter limits the operation to an open season of about six months. Dredging cannot be begun until there is sufficient thaw to produce water for flotation and to clear the ponds of the winter ice, which forms to a depth of from 5 to 7 ft. Both the start and finish of the seasonal operation are hindered by cold. All moving parts, such as the tailings conveyor, must be housed in and warmed by steam coils. Also, steam is used freely to keep the ladder and bucket line clear and to keep the gold tables in good condition. The dredging operation is terminated when the creeks freeze to such an extent that water for flotation is no longer available.

The creek deposits present many obstacles to dredging. In the first place, the deposits are shallow, which causes many moves of the dredge, both "stepping ahead," as the operation is called, and side moves across the pond. The shallow ground also increases the labor for outside work, such as setting "deadmen," removing stumps, etc. The muck itself is not difficult to handle, if thawed, particularly if sandy in character, but it often carries, buried in it, stumps, roots and other material, which tend to choke the feed hoppers and cause delays. Digging the bedrock in order to recover the gold is the most difficult part of the process. It is slow, hard work that entails heavy wear on the entire machine and causes continual replacement of all digging parts. The greatest obstacle to dredging is the frozen condition of a large percentage of the creek gravels, which condition must be removed before dredging operations can be successfully conducted.

The short season during which it is possible to operate has led to many departures from usual methods. The determined effort is to get all that is possible out of the dredges in the short time allowed, and the result is a remarkably high efficiency for the time the machines are operated. For example, last season the dredges of the Yukon Gold Co. averaged 87.2% of the possible running time, as compared to a fair California average of 78%. Each season has shown a gain in yardage per dredge-hour over the season previous, until the present rate is higher in most cases than that of dredges of the same size in California, where conditions are much more favorable.

NO. 7 DREDGE ON UPPER HUNKER CREEK

NO. 3 DREDGE ON BONANZA CREEK

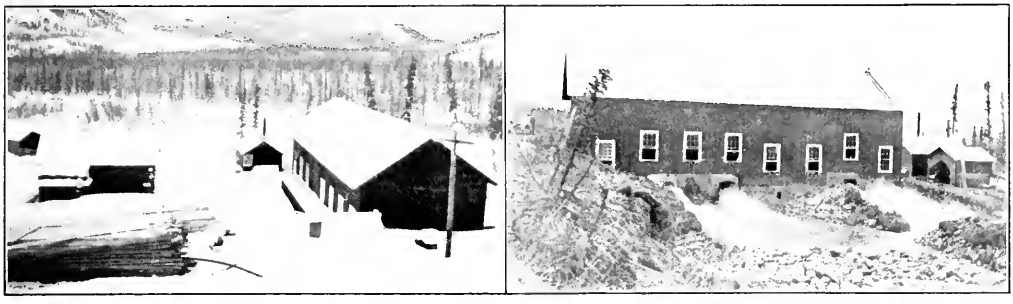
The No. 7 dredge completed its work on Upper Hunker Creek in 1911, and was then dismantled and removed to the Iditarod district, Alaska, where it has since had a remarkable yield from the rich ground on Flat Creek

How Repair Work Is Conducted

The California practice is to run the dredges continuously until they get to the point of requiring a complete overhauling, when they are shut down for 10 days or two weeks and the necessary repairs made. In the Northern practice this is changed. All the heavy repair work is done in the closed season. In the autumn, when work is suspended, the dredges are stripped of their bucket lines and conveyors. The buckets, screens, pumps and all parts subjected to heavy wear are taken to the shops and thoroughly overhauled. The dredges are put in a state of as nearly perfect repair as possible before the season opens

MACHINE SHOP AND WAREHOUSES OF THE YUKON GOLD CO. ON BONANZA CREEK

Dredge tailings and two dredges in background



POWER HOUSE OF YUKON GOLD CO. IN WINTER AND IN SUMMER

This power plant is situated on the Little Twelve Mile River. It contains three Pelton impulse wheels direct connected to three 650-kw. Westinghouse generators and supplies power to eight dredges, the machine shop and for other miscellaneous requirements

Machinery warehouse during flood of 1910 View below the power house in the spring of 1910

SPRING CONDITIONS THAT HAD TO BE MET IN THE YUKON IN 1910

and then operated with a view to keeping them going throughout the season.

During the operating season all repairing upon the dredge is minimized. Instead of replacing worn bucket lips on the dredge a few at a time, as is often done, the entire bucket line is taken off and replaced by another line which has been re-lipped and entirely overhauled. This operation requires only a few hours. The worn buckets are then hauled to the shop, repaired and kept on hand for the next replacement. If the distance to the shop is too great, the buckets are repaired on the ground by a shop crew. Portable compressors and special tools are provided for this work. The same method is used with lower tumblers and other parts exposed to heavy wear. When the lower tumbler plates become worn, instead of replacing the plates, the tumbler itself is removed and a newly repaired tumbler substituted. The old tumbler is then sent to the shop or repaired and replated on the ground, as the case may require. Each autumn all belting is taken off and sent to warm storage.

Strengthening Dredge Parts

Many detail changes have been made in the dredge machinery. The buckets have been re-designed several times since operations began. Some parts have been found to be inadequate for the heavy work. The digging ladders have all been reinforced and heavily shod on the bottom, screens rebuilt, pump capacity increased and sluices and gold-saving apparatus changed and improved.

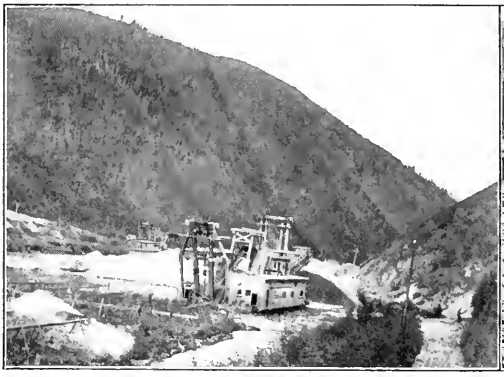
The closest possible supervision is kept over the running time and performance of the dredges. Each dredge is connected by telephone with the dredge office and reports its running time and stoppages daily. The superintendence is so arranged that the superintendent or his assistant visits each dredge at least once per day, and is on hand for any unusual repair jobs. In case of a shutdown for repairs, if only for a few hours, the crews are doubled up and shopmen sent out for any special work. Electrical repairmen are on hand day and night for any failure or trouble in the electrical apparatus.

As a further stimulus to increasing the dredging rate, a bonus system was tried during the season of 1912, but abandoned. The conditions varied so widely from one dredge to another, and the dredges being of a different age and in different condition made it difficult to arrive at a satisfactory standard of measurement. The bonus did not act as a stimulus, but rather aroused antagonism. The operators are all picked men, who get higher pay than they receive on other dredge operations, and a trip north, which they like. No further incentive seems necessary for the men to give the best that is in them.

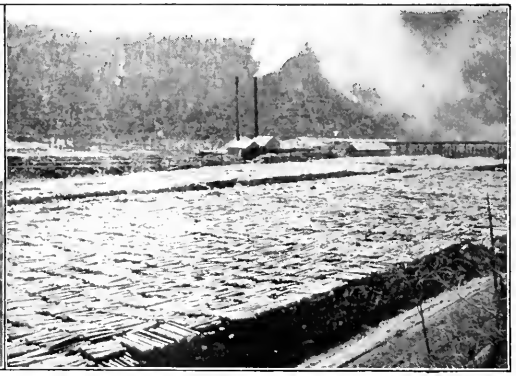
As illustrating the improvement in dredging in the Klondike since its inception, No. 5 of the Yukon Gold Co. dredged last season through the tailings of the old Lewes River dredge and made a good profit. This dredge took up 2 to 4 ft. of bedrock which the old dredge was unable to handle and obtained a good yield in ground that had been worked by hand by opencut methods before being dredged by the small dredge.

Frozen Ground the New Problem in the North

While the short season and severe service have led to numerous improvements in detail and to increases in strength and size of the dredges, and continue to offer problems which the dredge operator must meet, the greatest development in the Yukon as compared to the ordinary dredging operation has come in the handling of frozen ground. The heavy bedrock encountered on the creeks and the necessity of digging it to considerable depth to recover the gold were in themselves serious matters. No experienced dredge operator would have thought, in the beginning, that any dredge could handle the bedrock which the machines are digging today with comparative ease. When the business was further complicated by having large areas solidly frozen, the problem of dredging such areas at a profit became one of extreme difficulty. The results of attempts to dredge partly thawed areas and frozen bedrock were enough to show that the frozen condition must be completely changed before dredging could be successful. Necessity compelled the adoption of the present method of thawing, which is the development, on a wholesale plan, of the method which was in use in the drift mines in the Klondike before dredges were thought of. Preparing the ground for dredging by thawing with steam was an entirely new feature of dredge mining, and the success of the method has made millions of yards of gravel available for dredging which could not otherwise be worked at a profit.



TWO DREDGES ON UPPER BONANZA CREEK; THAWING PLANT IN FOREGROUND



OVER 7,000 CORDS OF WOOD STORED ON THE ANDERSON LEASE FOR THAWING

The steam point as originally used was a short piece of ⅜-in. pipe drawn down at one end to a point with an orifice left for the steam to escape; the other, or head end, had a nipple welded to it for steam-hose connection. The point, with steam turned on, was gradually driven into the face of the drift, then allowed to steam until the bedrock and gravel were thawed to the height of the drift. From two to six points were used in each breast, spaced from 1 to 2 ft. apart. This simple operation contained the essential features of the method whereby over three million yards of gravel are now being thawed in a season.

Thawing to a Depth of 40 Feet

In the thawing operation for dredging, the points are driven from the surface down through muck and gravel and into the bedrock from 4 to 6 ft. The points were gradually lengthened in practice, first, to 24 ft., then to 30, and last season were being successfully driven 40 ft. to bedrock. The points are made up of triple-extra-heavy hydraulic pipe with drop-forged head and tool-steel tip. The small boilers first used have been replaced by larger sizes until the boiler equipment now comprises eight plants with a total boiler horsepower of over 2000. The 150-hp. locomotive type has been adopted as the unit, and the plants usually consist of a pair or, sometimes, three such boilers.

The preliminary work for each season takes the following form: (1) The dredgeable area ahead of each boat is barred for frost. From the bar-hole results the naturally thawed and frozen areas are blocked out. The bar tests are checked by drilling where thought necessary. (2) Surveyors "pick up" the thawed areas which are mapped, and planimeter measurements are made of the frozen areas. (3) The estimated course of the boat is laid out for the year and its probable position calculated for each month of the season. (4) The total square yards of frozen ground which the dredge will dig in a season is measured from the map on which the season's work is laid out and the necessary wood for thawing is determined and its location decided.

The "sweating" of the naturally thawed ground must also be taken into account. The duty per cord, both in thawing and in sweating, to dispose of the surface frost, has been determined by experience. Knowing the square yards of frozen ground to be thawed and the area of naturally thawed ground to be "sweated" and the duty per cord of fuel, the total fuel requirement for the season is a simple computation.

The thawing operation has been described elsewhere[2], so that I need only give the sequence of events in a normal operation: (1) Steam-line boxes are strung out by horses, if they are available, otherwise men are used; (2) gooseneck boxes and headers coupled on; (3) bar-holes for starters put down; (4) starters used to thaw holes about 8 ft. deep; (5) starters pulled and long points placed in starter holes; (6) points driven down through gravel and into bedrock; (7) points allowed to steam in bedrock from 12 to 48 hr., depending on the formation; (8) points pulled, cleaned and straightened; (9) header moved and starters put down and cycle begun again.

The improvements that have been made in steam thawing since it was adopted for large-scale dredging operations are too many to attempt to detail in a short paper. They have taken the following general lines: (1) Reduction in fuel; (2) increase in efficiency of hose and points; (3) reduction in cost of driving.

The fuel has been reduced by improving the quality, reducing the radiation losses, purifying the feed water and improving the combustion. Experiments were made both with coal and fuel oil as a substitute for wood. The points have been greatly improved in material and manufacture, and the hose has been improved in quality and its life increased. Metal hose has been used for this work with success. The cost of driving has been reduced by improvement in the method of driving, correct spacing of points and correct pressure and amount of steam.

Costs Vary Widely Owing to Different Conditions

The question most often asked in connection with dredging in the North is: What does it cost to thaw and dredge frozen ground? This is a difficult question to answer on account of the wide variation in conditions. All of the creek deposits contain some areas of naturally thawed ground. The percentage of frozen and thawed areas varies on the same stream, and still wider variations occur from one stream to another. This variation reflects itself in the cost per cubic yard, the cost going up or down as the percentage of frozen ground increases or diminishes.

Another variable factor is the cost of thawing or preparing the frozen ground for dredging. Thawing on Hunker Creek, for example, is a much more difficult and expensive operation than thawing on Bonanza. In 1911 the thawing for dredge No. 4 on Hunker Creek cost $2.18 per sq.yd. as against $1.085 ahead of No. 5 on Bon-

[2]T. A. Rickard, "Min. and Sci. Press," Sept. 12, 1908.

anza. The depth being practically the same, the cost of thawing per cubic yard was twice as great in the one case as in the other. Purely local conditions govern this cost, such as depth of ground, character of material, ease or difficulty in driving, time of steaming, cost of fuel, etc. Since the gold, practically speaking, is all confined to the bedrock, the cost per square yard of bedrock thawed becomes the controlling factor in determining what ground can be dredged at a profit and what must be left.

The appended tables show the thawing and dredging cost for the last six years of the Yukon Gold Co.'s operation. Table 4 shows the variation in working cost for the different dredges in one season. As the conditions change, the dredge holding the lowest cost for one season may show the highest cost for the next. When the costs for the eight dredges are totaled and averaged the results over several seasons are remarkably uniform.

While Table 1 shows a gradual reduction in the thawing cost, it does not reflect the improvement in efficiency, which has been marked. It is a rare occurrence now for a dredge to strike a piece of ground that is not thoroughly thawed. The improvement in this direction is shown by the gain in duty per dredge-hour, which increased from 162 cu.yd. per hr. in 1910 to 204 cu.ft. per hr. last year.

I have previously referred to the operation of the Canadian-Klondyke company in the Klondike River valley. This company has built three 16-cu.ft. dredges, the largest size in use in California. The dredges have operated into December, making a total working season of 270 days. The president and general manager claims for the big dredges an operating cost of 6c. per cu.yd. No detail has been published showing how this cost is computed. As previously set out, the Klondike River gravels, where thawed, present exceptionally good conditions for dredging. It is doubtful, however, if as low a cost as 6c. per cu.yd. can be reached if the same items are included as given in the cost figures appended hereto. In the 1913 operation of the Yukon Gold Co. the items of gold tax and selling charges alone amounted to 1.98c., or practically 2c. per cu.yd. Depreciation, taxes, insurance, etc., add another 2c. in fixed charges, which would leave only 2c. per yard for labor, power, repairs and supplies if a 6c. cost were to be realized in this operation. However the costs of the Canadian-Klondyke company may be computed, they are undoubtedly low, and the company has contributed greatly to the development of dredging in the Yukon.

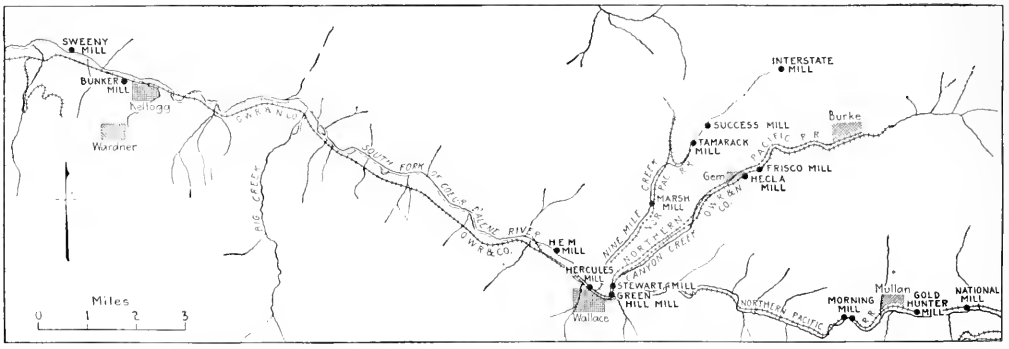
The development of another method I have not touched upon, as it is, as yet, untried for any large-scale operation, that is, the preparation of large areas of frozen gravel by the stripping method, or so-called "natural thawing." This method has been fully dealt with in a recent article[3] by E. E. McCarthy, who reports the results of the large-scale experiments conducted by the Yukon Gold Co. in 1906, 1907, 1908, and shows why the results were not such as to lead to the adoption of the method for its operations.

The dredging operation of the Yukon Gold Co. has added over $16,000,000 in gold to the wealth of the world; other companies have produced over $4,000,000, making a total of about $20,000,000 for Yukon dredging in less than 10 years of life.

[Since this paper was written, the total production mentioned in the last paragraph has been increased by about $4,000,000.—Editor.]

Flotation at Gold Hunter Mill

The Gold Hunter mine and mill, owned by the Gold Hunter Mining and Smelting Co., are situated in Hunter Gulch, about a mile northeast of Mullan, one of the mining communities of the Cœur d'Alene district. The orebody lies in the line of continuation of the Morning and You Like veins of the Morning Mine of the Federal Mining and Smelting Co. The mine has been operated since 1884, and while it originally produced high-grade silver ores, it is now in the same condition as the rest of the older mines of the camp, working on the comparatively low-grade and complex orebodies of the sulphide zone.



MAP SHOWING THE SITUATION OF THE PRINCIPAL CŒUR D'ALENE MILLS

Having approximately the same orebodies that exist in the Morning property, it is not surprising that the Hunter ores are complex and difficult to treat. The minerals known to be present are galena, sphalerite, pyrite, tetrahedrite, stibnite, siderite, barite and quartz. These minerals are unevenly distributed, and all of them do not occur in the general run of ores, although highly complex bodies containing many of them are sometimes encountered. As compared with the general character of the ore treated by the Morning mill, the Hunter ore supply contains more pyrite and less galena, but has a somewhat higher percentage of silver. In common with all the complex ores of the district, a great deal of difficulty

[3] "Min. Mag.," April, 1914.

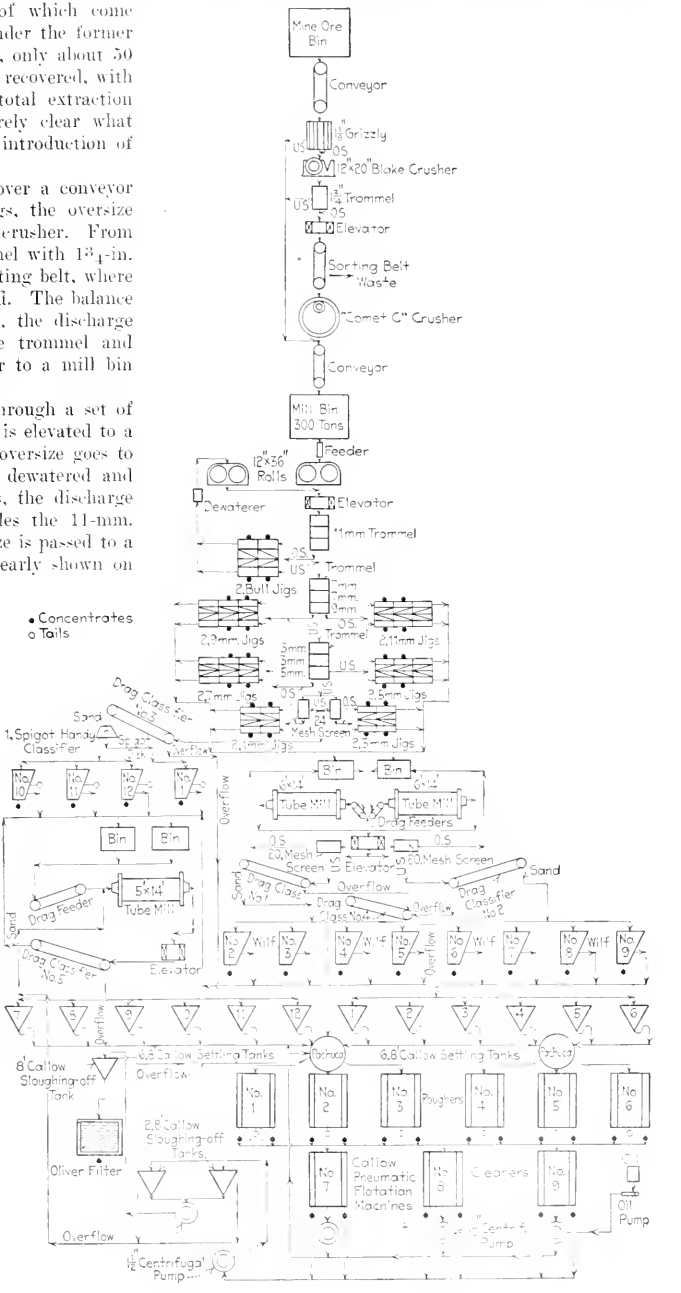
has been found in treating the Hunter ores profitably, and it may be said that not until flotation became a permanent part of mill treatment was continuously profitable operation possible.

The Gold Hunter mill at the present time treats about 310 tons of ore per 24 hr. From this about 35 tons of concentrates are produced, about half of which come from the flotation department. While under the former system of table and vanner concentration, only about 50 to 60% of the valuable minerals could be recovered, with the addition of the flotation units the total extraction has risen to 80%, thus making it entirely clear what a great difference has been made by the introduction of flotation in this district.

Ore from the mine-ore bin is passed over a conveyor belt to a grizzly having $1\frac{1}{8}$-in. openings, the oversize of which is put through a 12x20-in. Blake crusher. From the crusher the material goes to a trommel with $1\frac{3}{4}$-in. holes, the oversize being elevated to a sorting belt, where a portion of the waste is removed by hand. The balance of the oversize goes to a Comet crusher, the discharge of which meets the undersize from the trommel and grizzly and is carried on a belt conveyor to a mill bin having a capacity of 300 tons.

From the mill bin the ore is passed through a set of 12x36-in. rolls, the discharge from which is elevated to a trommel having 11-mm. openings. The oversize goes to two bull jigs, the tailings of which are dewatered and crushed in another set of 12x36-in. rolls, the discharge going back to the elevator which precedes the 11-mm. trommel. From the trommel the undersize is passed to a set of screens and jigs, the flow being clearly shown on the accompanying flow-sheet drawing. The sand is dewatered in a drag classifier and concentrated on four Wilfley tables, the concentrates from which are collected in a bin. The table tailings are then reground in a 5x14-ft. tube mill, elevated, dewatered and reconcentrated. The flow from the jigs is reground, classified and concentrated on Card tables, as is shown in the flow sheets. At this point preparation is made for treating the tailings from the concentrators by flotation. The pulp is thickened in Callow settling tanks and then delivered into two small Pachuca tanks, where mixture with the frothing oil is accomplished. Creosote oil in the proportion of about $\frac{1}{3}$ lb. per ton of ore is mixed in the tanks and then delivered to six Callow roughing flotation machines. Three of these are supplied by each of the Pachuca tanks. From the roughing machines the concentrates are sent to three Callow cleaners, these being machines of the same type as the roughers. Each of them is supplied by two of the rougher machines. The concentrates, finally cleaned, are pumped into two 8-ft. Callow sloughing-off tanks and then to a third Callow cone, whence they are delivered to an Oliver filter. The filter delivers concentrates containing only about 8% of moisture. All solutions from the flotation department are returned to the Pachuca tank for further use, the object being to avoid the loss of any oil that may remain in them.

The Callow machines are of the well-known light-froth type in which air is supplied through a filter bottom



FLOW SHEET OF THE GOLD HUNTER MILL

into the frothing cells. In this case the air pressure is about 8 lb. per sq.in., this pressure supplying sufficient buoyancy to keep a froth continually overflowing the cells.

Among the important points brought out in the practice of flotation at the Hunter mill is the absolute necessity of giving a great deal of care and watchfulness to the small details of operation. The flow of pulp to the roughing and cleaning machines must be absolutely constant in quantity, and what is even more important still, the dilution must be constant. At this mill the pulp is comparatively thick—that is, contains a high percentage of solids—but as a general rule of flotation this does not apply, since different dilutions may be necessary for the successful working of different kinds of ore. It is important, however, that after the proper working conditions have been determined, they shall be maintained absolutely to get proper results. The accompanying flow sheet shows clearly all the details of the operations of the Gold Hunter mill.

THE GOLD HUNTER MILL, NEAR MULLAN, IDAHO

Buys Ore Lands in Cuba

The Midvale Steel and Ordnance Co. announced Dec. 8 that it had obtained 300,000,000 tons of iron ore in Cuba through the purchase of all the stock of the Buena Vista Iron Co. The property owned by this concern lies adjacent to holdings of the United States Steel Corporation and the Pennsylvania Steel Co.

The company stated that improvements planned would entail the expenditure of more than $6,000,000. Those already outlined call for six new openhearth furnaces, a blooming mill and two turbo-generators for the Worth Brothers Co.'s plant at Coatesville, and of several additions to the Midvale plant at Nicetown, at a total cost of $2,380,000. The new facilities will enable the company to handle orders recently obtained from the Government for 14- and 16-inch guns 50 ft. in length.

Broad Pass Region of Alaska

Broad Pass is the western part of a wide glacial valley which is bordered by steep, straight mountain walls lying parallel with a great east-west range on the north and connecting the upper valleys of Chulitna and Susitna Rivers.

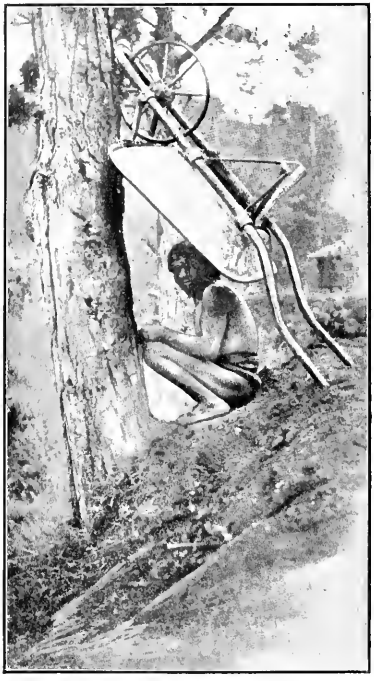
The geologic conditions in the region appear to be favorable to mineralization, but no valuable orebodies have yet been discovered. The most favorable reports came from the district just west of Broad Pass, near the head of Chulitna River, where prospecting has been carried on for several years. Valdez Creek, an important gold-placer district, lies about 30 mi. east of the pass. Along some of the streams between Broad Pass and Valdez Creek there are prospects of placer gold, which, however, has not been found in commercial quantity. Copper prospects, too, have been discovered in several parts of the region, and at one place, Coal Creek, there is a small area of coal.

The railroad, which will probably soon reach this region, will aid greatly in its development. The wealth of the Broad Pass region appears to be mineral rather than agricultural, and it can be profitably exploited only by a greater population and through better means of transportation.

The district is described fully in Bulletin 608 of the Geological Survey.

Safety First, Igorot Variety

The modern Safety-First idea, when applied by an aboriginal, does not always effect the security which it was intended to do, as shown by the accompanying illustration from the current issue of the Pan-American Union. The Igorot roadbuilder is safely(?) hiding under a modern American iron wheelbarrow upturned, awaiting the result of a blast on some road work nearby. He is showing the atavistic instinct of the ostrich by being apparently perfectly content with his safety precautions when he has protected his head from the flying rock, while the honorable torso is wholly exposed between the handles of the wheelbarrow.



SAFETY-FIRST POSE OF AN IGOROT

Details of Practical Mining

Compressed-Air Equalizing System at Copper Queen

By Fred M. Heidelberg*

Power for the Copper Queen Consolidated Mining Co., Bisbee, Ariz., was generated formerly at five of the company's shafts. About the middle of 1908 a central power house was built. Five 400-hp. Stirling boilers, with economizers and superheaters attached, were to furnish the steam, two 3,500-cu.ft. per min. Ingersoll-Rand compressors were to supply the air, while three 500-kw. Curtis vertical turbines were to furnish the electrical power.

The air consumption was the big variable and worked the greatest ravages on the plant. The compressors were connected directly to the air system. The governors on all compressors were controlled so as to keep the pressure about 90 lb. gage. The equipment using air consisted of three hoists—one Sullivan, one Fraser & Chalmers and one Nordberg—several hundred air drills and many other kinds of minor hoists and air machines distributed about the different shafts. It was found that since the Gardner hoist was so far from the power house, it could be run more economically on air than steam; therefore air was used, thus adding another Sullivan hoist to the air-consuming engines. More mine development made it necessary to install a 7,000-cu.ft. per min. Nordberg compressor to take care of the increased air requirements. The average consumption of air during the year 1912 was about 10,000 cu.ft. per min., while the maximum and minimum instantaneous requirements of the compressors were 14,000 and 2,000 cu.ft. per min. respectively. The minimum would take place between shifts when no air-using machines would be working. One 3,500-cu.ft. compressor would run at little more than half speed. The maximum was furnished when all three compressors were running at full speed.

Naturally, the maximum instantaneous supply would take place when all hoists and most of the drills were working at the same instant. The demand on the air system would be so great that all the compressors would jump from about half speed to full speed. Besides the undue racing of the compressors the demand on the boilers would be strong, since 30 lb. of steam for the Nordberg compressor and 40 lb. of steam for the Ingersoll-Rand compressors were required to produce 1,000 cu.ft. of air. Also, the air pressure would drop from 90 lb. to below 65.

Such conditions mean tearing the plant to pieces. Consequently, after a thorough investigation it was decided to install an air-storage and balancing system which would store up the air when consumption was light for use when the air consumption was large and keep the pressure nearly constant through a great part of the storage. This would allow fewer compressors in use and allow them to be run at a nearly constant speed.

General Features of the Design

In essence the plant consists of a steel-tank storage for air kept at a nearly constant pressure by a hydrostatic head.

The layout is shown in Fig. 1. The storage consists of six tanks, 9 ft. in diameter, 40 ft. long, spaced 11 ft. 6 in. centers. The volume of the six tanks is slightly over

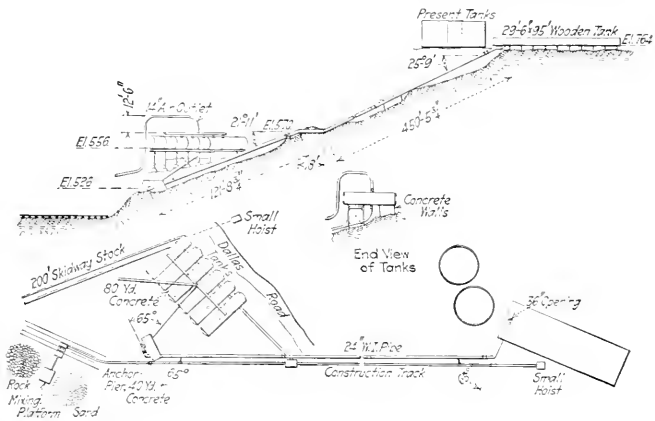


FIG. 1. GENERAL LAYOUT OF EQUALIZING SYSTEM

15,000 cu.ft., and they will store approximately 115,000 cu.ft. of free air at 93 lb. gage.

The air outlet at the top of each tank is 8 in. diameter and connects to a single-piece 14-in. header with 14x8 welded tees. The water inlet at the bottom of each tank connects to an 18-in. header by means of 12x18 tees welded to the header. This 18-in. header connects with the 24-in. line of the water tank by means of a 24x18 tee. The 24-in. line is of wrought-iron pipe and drops 30 ft. below the bottom of the tanks to form a U. At this U is a 24-in. gate valve. A 6-in. gate valve for draining and cleaning opens into the atmosphere at this point. From this U the pipe extends about 620 ft. to the wooden water-storage tank on top of the hill. The opening to the wooden tank is 36-in. and is connected by a 36x24 elbow.

There are five expansion joints in the pipe line, each allowing for a 2-in. expansion. Four of these expansion joints are between the U and the water tank and one between the U and the air tanks. Since one section of the long pipe is inclined at an angle of 21° 11′ and the other at an angle of 27° 11′, it would tend to slide down

*Box 1179, Bisbee, Ariz.

and close the expansion joints. Consequently an anchor pier 2x4 ft., top dimensions, extending with battered sides down to rock, was put in on the up side of each expansion joint to hold the upper section of pipe. Under each section of pipe a supporting pier 18 in. square on top was placed. At the U a large anchor pier was built. The pier was to have top dimensions of 6x21 ft. and was to extend with battered sides to rock not less than 4 ft.

Fig. 2 gives the details of the wooden water-storage tank. The dimensions are 29½x95x5 ft. The foundation

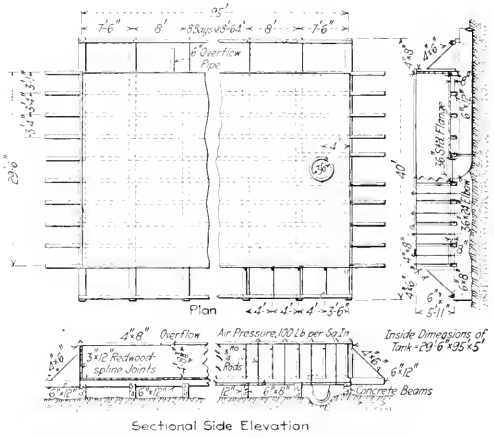

FIG. 2. DETAILS OF CONSTRUCTION OF WOODEN WATER-STORAGE TANK

consists of thirteen 12-in.-wide concrete beams spaced to make 95 ft. These piers are built on the rock and upon them were placed ten 6x12's spaced to make 29 ft. 6 in. The sides and bottom of the tank were lined with 3x12 splined redwood. The bottom of the tank was nailed to the 6x12's, while the sides were nailed to 4x6's. Braces of 4x6 were then inclined, as shown, to hold the sides plumb. A 4x8 cap was then placed around the entire periphery of the tank. Both a water outlet and inlet from the pump were provided.

The volume of the water tank is 2,800 cu.ft. per foot in height, which is slightly over one-fifth the volume of the air tanks. The total drop in head equals the drop in the water tank plus the rise in the air tank. The rise in the tanks varies for the same volume of water. At any rate one foot drop in head in the water tank displaces approximately 21,000 cu.ft. of free air at 93 lb. gage. This little example illustrates the delicacy of the system.

The water tank provides a large quantity of water with a small drop in head until the tank is empty. If there is just enough water in the system to bring the water to equilibrium when the air tanks are just full of water, the level of the water in the pipe will be about 108 ft. from the U, measured along the pipe. It is the volume from the bottom of the water tank to this point of equilibrium in the pipe that will produce the greatest drop in air pressure—that is, to zero gage. The length of pipe from this point of equilibrium to the bottom of the water tank is 512.2 ft., representing a volume of 1,630 cu.ft., approximately one-ninth the volume of the air tanks. This is a small quantity of air. It will be seen, therefore, that at no time should more water be put into the system than will just fill the air tanks at atmospheric pressure with the water at equilibrium.

The additional head of 30 ft. from the bottom of the air tanks to the U serves as a safety precaution. The air will just go around this point when the air pressure is between 103 and 105 lb. On a test at 103 lb. the system worked. When the pressure was raised to 105 lb. the air went around the bend and forced the column of water up with such force that part of the water-storage tank was wrecked.

The air tanks are supported at four places. The two back supports consist of concrete walls running under each tank. The two front supports are channel columns with channel struts between. The columns are directly under the tanks and were designed to take a load of 55,000 lb. each. Each tank rests in four cast-iron saddles, one over each support. Although the struts have no load to carry, they were designed to hold an empty tank at the center of the span, since the empty tank would be rolled over the beam in that manner while erecting. The curved air-delivery pipe is carried up 12 ft. 6 in. above the 14-in. header of the tanks to insure no water getting into the air system.

The distributing lines were located about as follows: In the power house the air discharge of all the compressors connected to a drum 4 ft. diameter and 80 ft. long. A 14-in. pipeline connected this drum with a smaller drain drum just outside of the power house. Two lines lead from this drain drum—one a 14-in. line connected to the balancing system several thousand feet away; the other, a 10-in. line, leads over to the Gardner shaft and

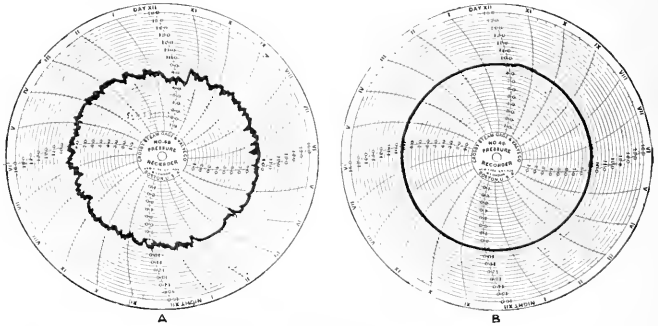

FIG. 3. CHARTS SHOWING PRESSURE CURVE BEFORE AND AFTER EQUALIZING SYSTEM WAS INSTALLED

supplies air to all the mines in the northern part of the camp. An 8-in. line connects to the 14-in. line near the balancing system, to furnish air to the Lowell shaft. Drain drums were provided wherever there was a dip in the pipe lines.

Constructing the concrete piers was simple. The concrete-mixing plant was located at the end of the railway spurs shown in Fig. 1. From this point to the top of the hill a construction track was run parallel to the pipe line. A small hoist was located on top to pull up mate-

rial. On the opposite side skids were installed with hoist, to handle the heavy tanks and material. The concrete was distributed as follows: Foundation beams under wooden water-storage tanks, 30 yd.; piers under pipes, 30; the anchor pier at U, 40; walls and piers under tanks, 80; total, 180 yd. The timber in the tank on the hill amounted to 22,400 ft. b.m.

In order that the right amount of water should be got in the reservoir, a set of gage-glasses were connected to one tank of the battery so that the height of water in the air tanks could be ascertained. By closing the gate valve the water in the storage tank could be kept from varying until enough new water could be added to bring the quantity to the required amount. Outside of keeping the required amount of water in the tank, the system gives no trouble. Its operation is automatic, and the pressure rarely varies over three pounds.

By way of comparison, two pressure charts are shown in Fig. 3. Chart A is an average one before the balancing system was installed, and shows the great variations in pressure in the air-supply system. It will be noted that in one place the pressure dropped and it was more than an hour before it could be brought up again. Chart B, on the other hand, was taken after the system was installed and shows very little variation in pressure during a 24-hr. period. These two charts tell the story.

Wash and Change Houses*

The value of change houses is not properly appreciated by the miners themselves, if the extent to which the houses are used is an indication. A great many men do not change their clothes on coming to the surface after a shift, but go to their destination in the clothes in which they have been working. The proper appreciation of the necessity of changing wet clothes, especially when the weather is severe, is a matter on which the miners need education. Several mine operators have erected commodious and well-equipped change houses only to have their proper use disregarded and the fixtures broken. The advantage to be gained by a wash and a change to clean dry clothes after work is a real one that makes for health and lessens exposure, but many, if not most, of the miners seemingly have not realized this, even where opportunity has been offered. The disregard shown by employees of companies that have erected change houses has probably influenced other operators to refrain from erecting or equipping similar buildings.

The value of change houses is a subject that can be handled in a general campaign of education among the miners; the necessity for such a campaign is great, and it is to be hoped that it will be undertaken in the near future. Mines that have no change houses should erect them. A plain wooden building, properly heated and having running water for wash purposes, is all that is essential. Shower baths, individual lockers, and otherwise elaborate structures, although of undoubted benefit where there are sufficient reasons for erecting them, are naturally not to be looked for where only a few men are working; but a warm shelter for changing clothes should be available, even at small mines. The exposure resulting from men going home a considerable distance in wet clothes in cold weather undoubtedly furthers disease, particularly tuberculosis, and to induce appreciation of this by proper education of the miners is one of the things that will help to reduce the prevalence of pulmonary tuberculosis in several mining districts.

The Bureau of Mines has published Technical Paper 116, "Miners' Wash and Change Houses," covering the subject of hygiene considerations and giving plans and descriptions of change-house equipments and an excellent bibliography.

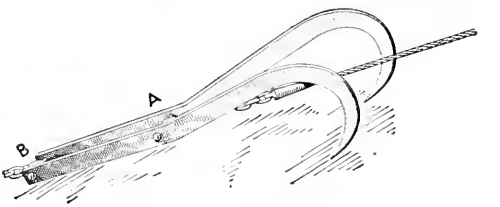
*Excerpt from Technical Paper 105, Bureau of Mines, "Pulmonary Disease Among Miners in the Joplin District, Missouri."

Runaway Tubs or Hutches

Under the title "Runaway Tubs," a correspondent of the *Iron and Coal Trade Review*, London, describes a method devised to prevent dropping of men being hoisted on an incline in case the hoisting rope breaks, as follows:

The risk run in lowering men down an incline or dook in hutches or tubs has again been brought to notice in the recent accident at Norton colliery, whereby two men were killed and nine injured. The speedy conveying of workmen to the various points underground has been rendered necessary by present conditions, and the practice has grown of taking a large number of workmen in one journey, thereby increasing the risk of injury.

To overcome or reduce to a minimum this risk the writer devised an apparatus—a sketch of which is shown herewith—to hold the train of hutches or tubs in case the rope should break when coming up or going down an incline. The apparatus consists principally of two flat bars of steel bent, spread and connected as in the sketch. The haulage rope is attached at A and the connection to the train of tubs is made



SAFETY HOOK FOR INCLINE HOISTING

at B. The sketch shows the connections clearly and indicates the spread of the bars necessary to clear the rope and pulleys and still be inside the rails. In a model the design was tested on all inclines up to 60°, and in every case, whether in lowering or raising, the hutches or tubs were held.

The writer would not recommend its use on roadways where short light rails are laid, but only on permanent laid roads. There is no fear of the hooks catching unless the rope breaks; so long as a strain is on the rope it is not possible for them to act. The appliance also prevents a sudden jerk being put on the rope through tubs catching when going down and then clearing; under such conditions the hooks would catch.

Resetting a Derailed Shovel

An old steam-shovel engineer, according to *Brick and Clay Record*, makes the following suggestion: If the front wheels are off of the track, fill the dipper with rock or other heavy material, loosen up one jack arm and swing the dipper over this side. This will raise the other side of the shovel. Put a number of men on the up-side jack and tighten it down as hard as possible. Swing dipper over high-side and screw down low-side jack. Continue this operation until the shovel is off the center bearing. If there is a key in the kingbolt, the trucks will be raised off the track.

If the rear trucks are derailed, lay blocks in the usual manner in order to assist the wheels to climb on the rails. If this is unsuccessful, drop the dipper and boost by means of the thrusting engines.

Details of Milling and Smelting

Baggaley Patent for Utilizing Heat of Molten Slag

U. S. Pat. 1,160,817, granted on Nov. 16, 1915, to the late Ralph Baggaley, of Pittsburgh, covers a method of utilizing the heat of molten slag by passing water, air, or other fluid to be heated, around a series of small receptacles into which the molten slag is poured. The apparatus suggested consists of a multiplicity of open-top conical slag "tubes" depending within a passage or container, and means for periodically inverting the device to discharge the cooled slag. One form of apparatus resembles a Walker casting machine, the lower part of the mold containing a water space connected with a central boiler and drum. A variety of constructions is shown for heating either air or water, all dependent upon passing the fluid around the depending tubes of solidifying slag and the periodic inversion of the slag tubes for the purpose of emptying.

This is a subject that has attracted the attention of many metallurgists, but owing to local conditions has seldom been worked out successfully. Mr. Baggaley stated in his patent that he had devoted many years to this investigation and had ascertained that the following features were either essential to, or at least seemed desirable in, the development of a successful apparatus for the utilization of molten slag:

1. The slag must not be able to shrink away from actual contact with its container at any time.

2. The slag must be delivered in such small units that it will congeal promptly.

3. A great number of such small units must be provided in order to obtain sufficient heating surface.

4. The volume of water to be heated must bear a proper proportion to the volume of slag which does the heating.

5. As the slag units congeal, cool and shrink, they should be free to fall by gravity so as to remain in actual contact with the container on all sides.

6. The slag-supply ladle should contain the same quantity of slag as the power-generator units, so that the slag may be poured quickly, without measuring.

7. The whole vessel should be well protected on all sides to prevent heat radiation.

8. As the slag tonnage is very large, the spent slag should be handled by machinery.

9. The feed water should be preheated to approximately 210° F., in order to secure proper efficiency in the apparatus.

10. The apparatus must be absolutely safe at all times against explosions or other accidents.

11. The free and complete discharge of the spent slag by mechanical means is important.

12. The possibility of water leaks into the molten slag must be absolutely guarded against to prevent disastrous explosions.

13. The apparatus must be durable in ordinary use.

14. The apparatus should not be more expensive to build than good boilers of the same capacity.

15. When the spent slag, after being discharged from the generator units, is used for the purpose of preheating the feed water, care should be exercised to prevent excessive sulphur in the feed water. This can be neutralized by any of the well-known chemical methods, or the hot spent slag may be delivered into a submerged container in the feed-water tank in a manner to prevent the slag from coming into actual contact with the feed water.

16. In order to provide sufficient heating surface, as well as to simplify the discharge of the spent slag, it is essential that the small slag units be located in one or more holding vessels which are separate and distinct from the boiler.

17. In order to maintain a supply of dry steam a dome or storage boiler should be provided, distinct from the water-storage boiler.

Handling Low-Grade Matte at Anyox, B. C.

The rehandling of low-grade matte is a problem at many smelting works. At the Anyox plant of the Granby Consolidated Mining, Smelting and Power Co., in British

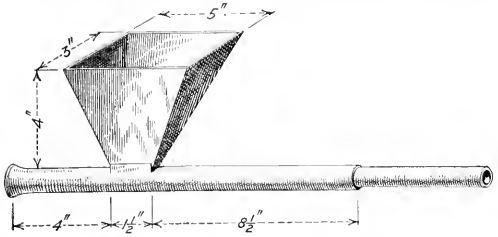
DRAG SCRAPER DIGGING AND LOADING MATTE AT ANYOX

Columbia, the management has eliminated much hand labor by applying the back-haul scraper principle to this problem. The low-grade matte is poured into long beds, and upon solidification the edges are broken with powder so as to give the special digging bucket or scraper a start. A donkey engine operates the digging bucket, which is pulled along on the bed, digs into the matte and is then hauled up the incline shown in the accompanying view. The bucket dumps into the railroad cars, and the matte is transported by a high line to storage bins and redrawn for the furnace charge.

Originally the converting of the first matte was done directly, but it was later found that it would be more economical to raise the grade by reconcentration. When resmelting was first started, the matte was stored in beds and dug up with pick and shovel. This was expensive, and it became necessary to find some mechanical way of doing it. The amount of hand labor and the cost of loading the matte have been much reduced. With six men, including the hoist man, as much as 600 tons of matte has been loaded in a day by the new arrangement. The objectionable feature of this method of loading is that the proportion of fines made is too great. This could be reduced by making shorter beds and thicker layers of matte, but the ground space at Anyox does not permit this improvement.

Cement Gun for Pointing Up Boiler Settings

A gun for squirting cement into the cracks of brick boiler settings is described by Harry Roebuck in *Power*, Dec. 7. From a length of brass tubing about 1 in. diameter was sawed a piece 14 in. long. Four inches from the end an opening ⅞ in. wide and 1½ in. long was cut with a sharp chisel, the tube being slipped on an iron rod held in the vise, while cutting. The cut was made along the center of the opening, and the metal was



CEMENT GUN FOR BOILER SETTINGS

bent out straight along the two sides. To the two sides was attached a hopper, 4 in. deep and 3 by 5 in. at the top, made of tin. The short end of the tube was given a flare of about a quarter of an inch, and a short piece of loosely fitting broom handle for a plunger completed the gun.

The plunger should not be too snug a fit, and the sand should be screened through a fine screen, or trouble will be experienced from sticking of the plunger. By rinsing the apparatus in a bucket of water each time before loading, the cement will flow more freely.

Making Babbitt Castings

A recent article on babbitt casting, by J. H. Van Deventer, in the *American Machinist*, embodies the following points.

If babbitt is heated to over 900° F. the chances of getting a scaly job are very good. The high limit is 850° F., which is too high to be tested with the finger, but can be judged from a pine stick, being the point at which such a stick when thrust into the metal hesitates whether to burn or not and finally decides to do so. This is too hot for pouring, unless the shell to be run is less than ⅛ in. thick. For ordinary work the metal is right to pour when it will char the pine stick but not produce flames.

There are three kinds of hand ladles for pouring babbitt—the good kind, the bad and the indifferent. A good ladle is one with a lip designed to pour a heavy *solid* stream. That is, a ladle with a rounded lip, preferably with a dross dam, is best.

When remelting scrap, boil green hickory wood with the metal to remove the dross. Beware of blowing out a cast-iron shell with compressed air before babbitting. Air lines contain water, and this won't mix with babbitt. Hand bellows are safer. A large casting too heavy to lift can be dried by burning gasoline in it. Use sal ammoniac in the melting pot if you want clear metal.

Remember that a thin section will cool quicker than a thick one and must be poured hotter. Remember that powdered rosin sprinkled and rubbed on a damp job will prevent explosions. Smoking a mandrel with lamp black will do if rosin paper or clay wash is not available. A heavy cord dipped in clay wash will act as core for an oil groove.

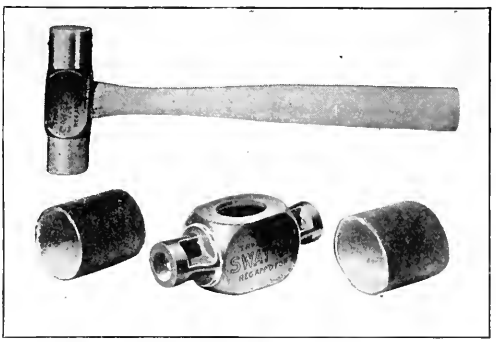
Slow cooling makes bearing metal coarse-grained. Open up the box as soon as the babbitt is cold. Dirt and dust rise to the highest point on the mold. Risers and a high pouring gate will get them outside of the bearing.

If you must pour a bearing cold, use a mixture that contains plenty of antimony. It won't shrink as much as other mixtures will. Remember that air is lighter than babbitt and vent at the highest point. You cannot depend on air getting out where the babbitt goes in. Give it a private exit. Overheated metal, lack of proper vent and slow pouring are back of most spoiled bearings. Hence, last and most important of all, *pour quickly*.

Soft-Metal Hammer

The soft-metal hammer shown is intended not only for general machine-shop use, but also for sheet-metal work, garages and repair work of various kinds.

The body of the hammer head is made of tough bronze that is practically indestructible, and it will stand all



SOFT-METAL HAMMER HEAD AND MAILING TUBE MOLDS

the reheating necessary to melt out the old metal preparatory to renewal. It is so made that short sections of paper mailing tubes may be used as molds for the soft metal. The lower picture shows two of these sections and a bronze head.

The hammers are furnished with handles and soft ends in 1-, 2-, 4- and 6-lb. sizes. They are recent products of the Bauth Manufacturing Co., 901 Gerke Building, Cincinnati, Ohio.—*American Machinist.*

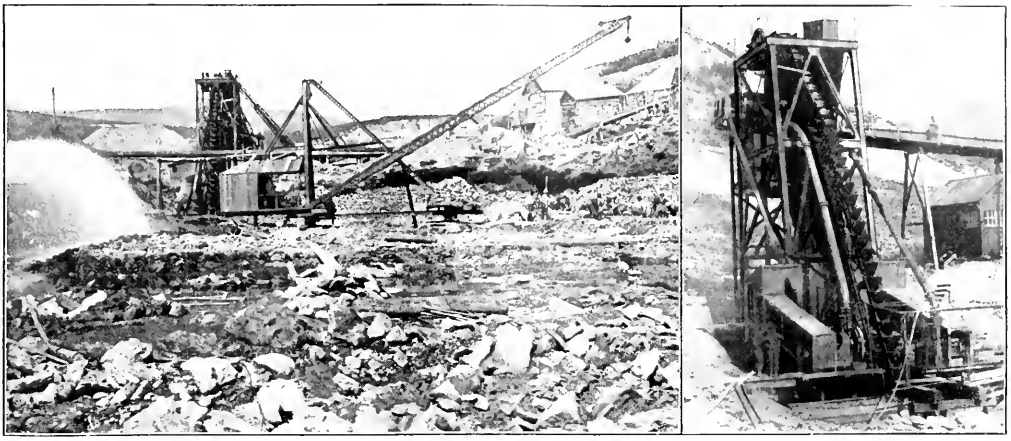
CLEANING BEDROCK AT ELEVATOR No. 3. PREVIOUS TO THE APPLICATION OF DREDGING THE BONANZA CREEK GRAVELS WERE HANDLED BY HYDRAULICKING IN CONNECTION WITH MECHANICAL ELEVATORS. LOWER VIEW SHOWS THE UPPER SLUICE OF ELEVATOR NO. 3



MECHANICAL ELEVATORS USED BY YUKON GOLD CO. IN THE EARLIER OPERATIONS ON BONANZA CREEK

Hydraulicking in connection with portable mechanical elevators was abandoned on Bonanza Creek when it was found that the dredges could be built strong enough to dig the bedrock and handle the large boulders or slabs that may be noted in the foreground of the above picture. The derrick shown in the center background was used to facilitate the removal of boulders and bedrock slabs preparatory to cleaning bedrock. The dredges now dig this bedrock and operate more cheaply than the elevator method. At the right is shown a nearer view of one of the mechanical elevators. These elevators were mounted in a portable steel frame, fitted with flanged wheels. The excess water is elevated from the pit to the sluice by a 12-in. centrifugal pump driven by 100-hp. motor. There was also a 10-in. auxiliary pump used when a rush of water was encountered

Library Service Bureau

The Library Board of the United Engineering Society, in order to bring the usefulness and facilities of the engineering library closer to the individual members of the profession, has inaugurated a service bureau which will maintain a staff of expert searchers and translators for researches and translations for those who are at such a distance from New York that they are unable to avail themselves of the facilities of the library.

The service bureau has also arranged to keep those who may desire it posted on the current publications of any engineering subjects that they may specify. In this connection, reference cards giving the title, author and exact citation of all published articles on the subject are mailed to the subscriber. Then, if copies or translations are desired, they will be furnished on application, at previously stipulated prices.

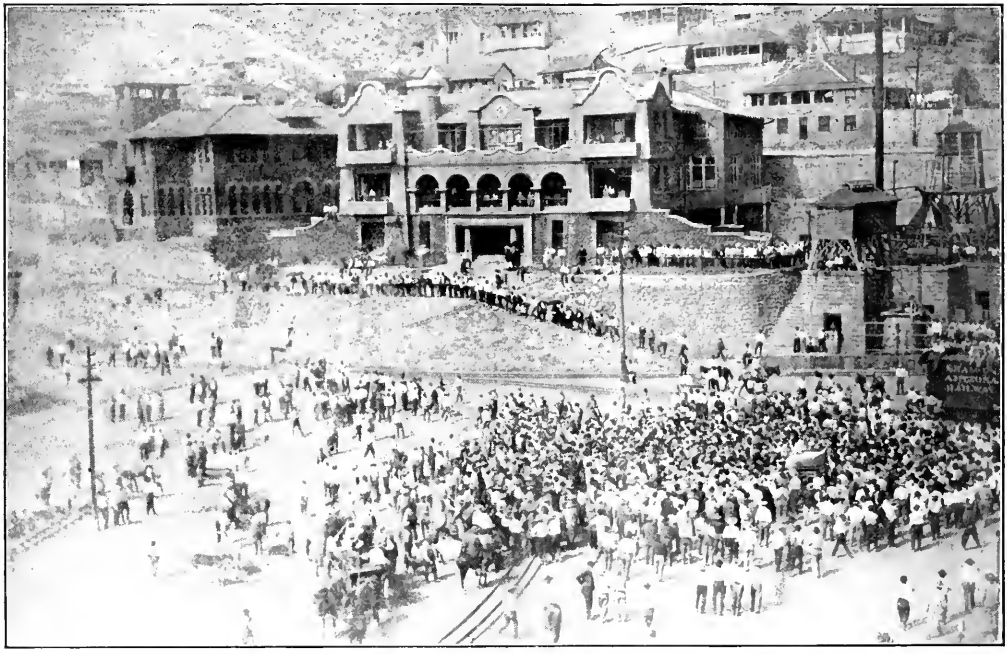
The prices charged for this work are kept down to the merely self-supporting basis, because the United Engineering Society does not carry on any work of a commercial character.

The engineering library has over 60,000 volumes on technical subjects and receives currently over 1,000 engineering and scientific periodicals. In addition, access is had to the New York Public Library and the library of the Chemists' Club, so that researches can be covered on almost any engineering subject.

Requests for information and rates should be addressed to the Library of the United Engineering Society, 29 West 39th St., New York City. E. Gybbon Spilsbury is chairman of the Library Service Committee, which is making every effort to bring this service to the attention of the profession at large, for whom it is designed and to whom it is conceived to be of great potential benefit.

The Clifton-Morenci Strike

The Lake Superior strike of 1913 introduced many features of labor warfare that were humorous in their very outrageousness. The Clifton-Morenci strike is even more picturesque. One of the accompanying illustrations shows the concentration camp. What? Of strikers, or strike-breakers? No. Simply of miners who would like to go to work and are not permitted to do so by the labor leaders, aided and abetted by the county and state officers.



STRIKERS IN THE CLIFTON-MORENCI DISTRICT OF ARIZONA LISTENING TO A WESTERN FEDERATION SPEECH IN FRONT OF THE MORENCI HOTEL

It's hard to get news from Clifton and Morenci. The correspondent, or indeed anybody else who enters town, has first to pass an inspection something like what an entry into Russia used to entail. If the sheriff and the labor leaders pronounce him O. K. he gets 24 hr. in which to transact his business and depart. However, if during his visit he turns out to be a *persona non grata*, he is apt to be caused to depart on shank's mare and barefoot. If *non gratissima*, tin cans are tied to his person, which also is appropriately placarded according to the views of the labor leaders and officers of the law.

It looks as if democratic government had ceased to exist in this part of Arizona. Irvin Cobb or Sam Blythe ought to go there as war correspondents to tell the country about the death of liberty in a part of the United States. However, if we were their editors, we should not

venture to send them there unless we could get von Mackensen to help.

We hear, however, that the property of the mining companies is being taken care of fairly well. The sheriff is attending to that, and nobly is doing his duty. He is hiring a corps of deputies to guard the property. He hires them among the strikers. Thus as deputies they are guarding what as strikers they are threatening. The mining companies are paying the wages. Herein we have a truly humorous situation. As a financial arrangement it is something like that of the cat and rat farm.

Copper in Germany

The following interesting article by Gilbert Hirsch, its Berlin correspondent, recently appeared in the New York *Evening Post* (copyright, New York Evening Post Co., 1915), by whose courtesy we reprint it, only slightly condensed. It was dated Oct. 21. The comments that are introduced are our own.

There is no copper famine in Germany; there is not going to be one. England, to be sure, has decreed that no American copper shall go to Germany, and no American copper goes there. Some copper did get through by way of Holland and Scandinavia in September of last year; but England put an end to that by bringing pressure to bear on Holland and the Scandinavian countries. This interfered with the business of Scandinavia and Holland, prevented Italy from getting some of the copper which she needed to arm herself for participation in the war, cut down the output of the American copper mines and caused a boom in the German copper industry. As to the ultimate object—a shortage in the German ammunition supply—it does not exist and is not in prospect.

The cutting off, to be sure, of the 35,000,000 lb. of copper which Germany was accustomed to get from America every month has had an appreciable effect. In times of peace Germany, the second largest copper manufacturing country in the world, makes articles containing 225,000 tons of copper. This year it makes none of these articles, devoting its entire copper supply to military purposes. No copper money is minted, and the resulting shortage in small change is already making itself visible in the requests posted in many retail stores, that customers give the exact change in payment. You hear of how carefully the copper from used ammunition is being saved; of the rounding up of all the available copper in every position captured from the enemy. You see women walking through the streets carrying between them copper kettles or gramophone horns to sell to the authorities. If you are a householder, you are invited to fill out long detailed forms describing everything you have made out of copper or brass and specifying whether or not the artistic or historical value of each piece is double the value of the raw material contained in it; for the German government has determined not to melt down anything that might be considered a work of art.

Precautions Against Shortage

From all these symptoms one might conclude, if not acquainted with German psychology, that Germany is face to face with a real copper famine. But all these measures, like the use of the bread-card, and the prospective milk card, are precautions against a shortage and not the confession of one.

At the outbreak of the war Germany had more than 75,000 tons of raw copper—much of it American copper—on hand in factories and warehouses. Measures were at once taken to increase the ouput from the German mines. In normal times they produce some 50,000 tons yearly.[1] Since the war began many of them have increased their production more than 50%. But the chief recourse of the military, in case of pressing need, will be the old copper. It is impossible to estimate exactly how much there is in a country which, like Germany, has been mining copper for a thousand years. Yet no doubt the German lust for statistics will be satisfied here as it is everywhere else. A few days ago the householders sent in to the proper municipal centers their blank forms all *regelmässig* filled out, and the necessary computations will be very quickly made.

The government has announced that it will begin buying up these articles, if it finds such a course necessary, by Nov. 16. It is not believed that these compulsory sales will actually take place in November, nor in six months from November, for the amount of copper which the government has already received through voluntary sales is said to be enormous. The price paid is an extremely good one—1.3 marks per kg.—that is, about 37c. for 2¼ lb. The German government which is, just now, poor in so many things, is, thanks to the unexpected success of its war loans, very rich in money. And its liberal payments for copper within the past year have enabled many a poor family to live for months on the proceeds of its own kitchen utensils.

One hears the hope frequently expressed on the part of housewives, and with a great deal of fervor, that these voluntary sales will make a later confiscation unnecessary. I have heard a woman discuss, with tears in her eyes, the possible loss of a copper and brass wash-tub which had cost her no end of time and trouble to keep clean, just as she might discuss the possible loss of a troublesome but dearly loved son on the field of battle. There is, in the German woman's love of her copper things, an intensity that is peculiarly racial. One feels as if, in some mysterious way, the Germans must belong to those races, like the ancient Persians and Egyptians, among whom copper, and not gold, was the royal metal.

As the German production of copper wares for home consumption has amounted in recent years to an average of 125,000 tons per annum, there is no question that the supply on hand is enormous. Not all of it, of course, is in private possession. There are hundreds of thousands of tons in street-railway wiring. And when, a couple of days ago, I put the copper problem to one of the persons most intimately concerned with the stretching of all Germany's resources, the answer was:

"Our roofs. Take a city like Dresden, where so many of the roofs are of copper. If we get hard up, we just have to go down there and take the roofs off a few *Rathhäuser* (municipal buildings) and we are saved." And there are many roofs in Belgium and in northern France which can also be used, if need be, for the same purpose.

And if the worst comes to the worst, a substitute can be used. To those who are familiar with copper and its peculiar qualities, this sounds like an impossibility. But

[1] The most authoritative statistics credit Germany with a copper production of 25,000 metric tons in 1913, which was larger than the average for several years immediately preceding. The official report of the Mansfeld mines, the principal producer, showed no increase in 1914.—Editor.

the German chemists and physicists during this war have obeyed the order "invent" in much the same spirit in which the German soldiers have obeyed the order "fire" or "charge." When a substitute for a thing has to be invented, it is invented. There have been invented since the outbreak of the war substitutes for rubber, for eggs, for wool, for meat, for leather, for string, for coal, for gas. In Germany the same word is used to indicate a substitute for a thing and a reserve regiment for the army—*Ersatz*. It is said that the substitute for copper has been found in a soft steel.

That it is not expected that a substitute for copper will be needed for a long time to come, however, is sufficiently proved by the fact that the copper mines of Germany are not being worked nearly as intensively as they might be, if the situation were considered serious. I visited the other day the Rammelsberg mine in the Harz Mountains, which belongs to the state. I found that it has had its working force materially reduced since the outbreak of the war and that there are only one and a half shifts a day, of eight hours each. The fact that in spite of this it now produces considerably more than before the war is due to a concentrating on the production of copper and cutting down materially on the mining of lead, of which, in peace times, four thousand tons was annually produced from ores taken from this mine.[2]

Romance of an Old Mine

The story of this oldest copper mine in Germany is full of romance. History has it that the mine was discovered and worked by the Franks in those distant days before the Germans understood the art of fashioning copper. But the tradition is that it was one of the knights of Emperor Otto First—the Ritter Ramm—whose horse laid bare some ore with a beat of its hoof. Traditions die hard in the Harz Mountains. The very price fixed by Emperor Otto for the carting of a wagonload of ore—nine pfennigs—holds to-day. And the miners of these days are said to be the direct descendants of the miners then. They cling to their peculiar superstitions, to their bizarre costume, to their custom of assembling in church every Monday morning before going into the mine, to pray for their safety while in the bowels of the earth, and to their ancient form of salutation *Glückauf!* which is a pious hope that you may return safely to the surface of the earth.

In the market place of Goslar, half a mile from the mine, and itself a thousand years old, is a great bell, on which the citizens used to beat whenever there was danger of attack, to call the miners out of the depths of the Rammelsberg mine to help in the defense. The bell is no longer rung. But the same obligation to give up their work at a moment's notice to help in the national defense is still on the men who work in this mine. Nor does the fact that this mine belongs to the state—a three-sevenths share belongs to the province of Brunswick, the remaining four-sevenths to Prussia—nor that these men are doing work essential to the defense of Germany make any difference. When the war broke out, every miner of the specified age, who could pass the physical examination, had to go. And only the fact that this mine happened, at the time, to be employing a large number of men past fighting age, saved it from serious embarrassment. I have been told that the miners are well thought of in the field. Most of them are assigned to pioneer regiments; but I have heard of one who—no doubt for variety's sake—joined the flying corps.

A German Mining Town

To speak of Goslar as a mining town might give a wrong impression, since it reminds one of a scene from "Meistersänger" or "Faust" rather than of the grimy streets of Butte or the abandoned shacks of Virginia City. But the city has lived for a thousand years from the steady flow of metal from this one mine; its history has largely consisted of battles between rival nobles for the possession of the mine; its fine old monasteries and churches were due less to a particularly religious spirit in the town itself than to the desire of the clergy to make quite sure of receiving their full tithe from the mine, by being on the spot. In the Middle Ages it was one of the most strongly fortified towns in Germany, completely walled, and defended by 180 towers (of which three are still standing) which could not have been built but for the wealth that the Rammelsberg mine brought into the coffers of the city. And the defense was carried on by nobles who had made the city their residence in order to seize some of the precious metals from the mine and—in a literal sense—make money out of them. For the mine still turns out as much as 75 kilos of gold and a hundred times that quantity of silver every year.[3]

The story of this German mining town is a sufficient answer to those Americans who claim that it is our "commercialism" that keeps us from being as "picturesque" as Europe. Goslar has attained its present distinguished appearance through the fact that it has been doggedly commercial for ten centuries. The very Kaiserhaus on the hill above the town, of which the Germans are so proud, would not have been built there had it not been for the mine, whose riches were the determining factor with Henry II (despite his sobriquet, "the Saintly") in fixing on Goslar as the capital of the "Holy Roman Empire" in the eleventh century.

I went into the mine itself, 450 yd. below the surface. No horses are used in the interior to carry out the ore—and no boys under 19, the German law fixing this age as the minimum for underground employment being strictly observed even in war time. [Some lines here have been cut out by the censor.] We went through miles of passages roofed by ore containing lead which looked like flashes of silver, copper which looked like streaks of gold, and zinc which looked like deposits of copper, past men boring into the sheer rock with compressed-air drills, past elevator shafts and emergency shafts.

As we were down below the very center of the mountain, one of the men from another mine who accompanied us, asked the manager of the mine whether he believed in the *Wünschelrute* (the divining rods by which, according to an old belief, it is supposed that one can tell where the rich deposits are). He himself, he said, was

[2]The Rammelsberg mine, a famous and interesting ore deposit, has never been aught than an insignificant producer of copper in modern times.—Editor.

[3]The author is here describing the mining customs of the Harz, an extensive and picturesque district, rather than of the Rammelsberg mine alone. That mine is in the lower Harz. Goslar and Oker are the nearest towns. In the upper Harz the best-known town is Clausthal, where there are numerous mines, the ore being taken to Lautenthal and Langelsheim in the lower Harz for smelting. All of these are classic names in mining and metallurgy, but like that of Freiberg in the Erzgebirge, their industrial importance waned many years ago.—Editor.

absolutely convinced that it has properties that are as good as magical. But the manager laughed.

"I believe only in my Bible," he said.

"Your Bible?" I asked.

"I mean the American *Mining Journal*," he said, smiling. "We all read it religiously. For years the rates cited in it, rather than the prices listed in the German journals, have been the basis of the German mining trade. Since the outbreak of the war, the English have kept all other American mining products from us."

The shoot of ore in this mine is wider than anywhere else in the world, is extremely rich in copper, in some cases yielding as much as 22% metal. But it is a comparatively small mine, employing, together with the Oker smelteries, with which it is affiliated, only about 2,000 men. This is far less than the Clausthal mine, in the Upper Harz, to say nothing of the mine at Mansfeld, the largest copper mine in Germany, and the one at Eisleben, in Halle, which also produces an enormous quantity of zinc and employs 10,000 men.

When we came up to the surface the "Mr. Mountain Inspector"[4] (as the manager of a mine is quaintly called), after showing me the various safety devices insisted upon by the German government, took me into a building where there was an apparatus which had been insisted upon—more or less indirectly—by the British government. It was a plant, just completed, for the manufacture of liquid air, which, as I learned, is being substituted for dynamite in all the principal mines of Germany, now that the supply of Chile saltpeter has been cut off.

Liquid Air for Explosive

The use of liquid air as an explosive has been known ever since the famous Professor Linde took out the first patent in 1895. It was used in the building of the Simplon Tunnel, and has been tried in a number of countries, notably France. But until very recently it was regarded as still in the experimental stage. Immediately upon the outbreak of the war it was put into practical operation throughout the German mining industry. The results have proved so successful that it is now certain that it will continue to be used in place of dynamite even after the war.

In the first place it is peculiarly safe. You can take a cartridge—as they call the little black mouselike bags—put it into the bucket of liquid air which, literally, steams with cold, until the cartridge has soaked up 90 gr. of it, and then, with the assurance that you are dealing with an explosive more than half again as powerful as the ordinary charge of dynamite, you can put it down and step on it, and the only result is a fizz as of so much steam. I saw five of these cartridges jammed with a stick into the holes drilled in the rock, just as if they had been so many wet rags. And then I saw the men running like mad, when the electric current was turned on and the pieces of rock began to fly.

The cheapness is another advantage. Over against 20 pfennigs, the approximate cost of a dynamite cartridge, one cartridge saturated with liquid air costs, at this Rammelsberg mine, only 12 pfennigs. And where it is made in larger quantities, the cost is even less. A whole new industry is in the process of development in Germany to manufacture and handle liquid air; and the principal firm, the Marsit Corporation, declares the cost of liquid air to be just one-half that of dynamite.[5]

[4]Berginspektor = mine inspector. The literal translation is more humorous than accurate, whatever be the derivation of the term.—Editor.

[5]The use of liquid air was described in recent issues of "Stahl und Eisen."—Editor.

Revision of Mining Laws

The meeting of the Mining and Metallurgical Society of America in collaboration with the American Institute of Mining Engineers, the American Mining Congress, the Idaho Mining Association, the Montana Society of Engineers, the California Metal Producers' Association, the Spokane Mining Men's Club, the Nevada Mine Operators' Association and the Colorado Scientific Society, together with representatives from several chambers of commerce and many operating mines, was well attended. Many delegates came from distant states, including South Dakota, Montana, Idaho, Oregon, California, Utah, Arizona and Colorado. Organizations unable to be represented communicated resolutions in approval of the purpose of the meeting.

The first session was called to order by W. R. Ingalls, president of the Mining and Metallurgical Society of America, who briefly stated the purpose of the meeting. The idea was to impress upon Congress the earnest wish of the mining industry that the archaic mining laws of the United States be revised; that a commission be promptly authorized for this purpose. In this program all of the mining societies and the mining press of the country had united. While the present meeting was being held under the auspices of the Mining and Metallurgical Society of America, the other national organizations and the several state societies had been invited to collaborate and were doing so; also the chambers of commerce in the mining towns of the public-land states; moreover, through the medium of the Bureau of Mines, every mine operator of the United States had been invited to participate.

The rules for the conducting of the meeting were then read and approved, and the appointment of the following committees was made: Credentials—J. F. Callbreath, George Collins and George C. Stone. Rules—J. Parke Channing, S. W. Mudd and Frank A. Ross. Resolutions—H. V. Winchell of Minneapolis, Minn.; E. B. Kirby, of St. Louis., Mo.; Hennen Jennings, of Washington, D. C.; Walter Douglas, of Bisbee, Ariz., and John Kirchen, of Tonopah, Nev.

The chair was then taken by Carl Scholz, president of the American Mining Congress, who introduced the first speaker, E. B. Kirby, of St. Louis. Mr. Kirby made a general presentation of the bad situation that has come to pass under the mining law of 1872, which for 43 years has stood unrevised, although the knowledge of ore deposits has increased enormously during that time.

Following Mr. Kirby, Hon. Franklin Lane, Secretary of the Interior, made some graceful remarks extolling the importance of the mining industry, welcoming the mining men to Washington, and in concluding stated that he would anticipate his forthcoming annual report by informing the meeting that he recommended a revision of the mining laws. "The old code," he said, "is so elaborate and complicated that the best of brains cannot tell what the law is. The truth seems to be that between mining engineers and mining lawyers the rules of the game

have been refined into obscurity; and if Congress were to say to the President that he might select three men familiar with mining laws and miners' difficulties to suggest a new mining code to Congress, it would, I believe, be giving in earnest a new freedom to the mining industry."

The next address was by Hon. E. T. Taylor, member of Congress from Colorado, who read the bill that he had introduced in the House of Representatives on Dec. 6 (H. R. 18) and explained its provisions. Mr. Taylor remarked that the total representation in Congress from the public-land states was but a small proportion of the membership: that the representation from the Eastern, Southern and Middle States is not much interested in such a question as mining law revision; that he is the only member of the committee on mines and mining who is from a mining state. Congress, he said, is becoming more and more averse to the creation of commissions. In his bill he had provided for an unpaid commission, considering that the House of Representatives would be more likely to agree to that than to a paid commission, and he for his part being hopeful that five men sufficiently patriotic to give their services to the Government would be found. The exemption of coal, oil, phosphate and potash lands from the scope of his bill was introduced at the request of the Administration, which has a well-defined program respecting them.

Mr. Taylor made a very excellent impression, both on account of his sincerity of purpose and his thorough knowledge of his subject. For the purpose of discussion the bill introduced in the Senate by Senator Smoot was also read.

A lively debate respecting the merits of the two bills ensued, especially with regard to the composition of the proposed commission and the having a general revision or having a revision with certain classes of mineral lands excluded. The general opinion appeared to be that the revision ought to be of the broadest character and that the commission should consist of mining men rather than mining lawyers.

F. F. Sharpless, secretary of the Mining and Metallurgical Society of America, introduced the resolutions that were to be offered by that society. By agreement of the meeting, other resolutions were read by title and referred directly to the committee on resolutions. That committee was also authorized to frame and introduce resolutions at a subsequent session.

The second session was opened at 2:30 p.m. with William L. Saunders, president of the American Institute of Mining Engineers, in the chair. The first speaker was the Hon. Reed Smoot, United States Senator from Utah, who made an impassioned address, voicing the demand of the mining industry that the archaic mining laws be revised. He explained the provisions of the bill that he had introduced in the Senate and announced that on that day it had been reported favorably by the committee on mines and mining and had been put at the head of the Senate calendar.

Following Senator Smoot, an address upon the need of revising the mining laws in the light of modern knowledge of ore deposits was made by Dr. George Otis Smith, director of the United States Geological Survey. J. Parke Channing then gave a talk, illustrated by lantern slides, upon the conditions existing in the Miami district of Arizona, illustrating a case where the law of the apex is utterly inapplicable and was abolished for the district by the common consent of the mining companies.

Horace V. Winchell then offered, in behalf of the committee on resolutions, the following that had been agreed upon by that committee:

1. The mining law of the United States should be revised, not piecemeal, but thoroughly, so as to coördinate and harmonize its various provisions.

2. For the purpose of giving the fullest consideration to the needs of every branch of the mining industry and every section of the country as affected by the mineral-land laws of the United States, it is desirable that a Government commission be created by Act of Congress, whose duty it shall be to investigate by every proper means the questions and interests here referred to, and to make recommendations as to a basis for the proposed mining-law revision.

3. That in order to represent the classes of men whose interests will be affected, the proposed commission should consist of five members: One representing the legal profession, one representing the Department of the Interior, and three men actively interested and experienced in mining and the acquisition and handling of mineral lands.

4. That this commission shall be selected and appointed by the President of the United States.

5. That this conference believes that the services of such a commission are deserving of compensation, as well as reimbursement for all necessary expenses, but is more concerned with the actual establishment of the commission and its character than with the question of emolument, and will gladly see the work done through an honorary commission if Congress deems it advisable.

6. That this conference expresses itself in favor of the creation of a permanent committee on mining-law revision, such committee to consist of five members from the Mining and Metallurgical Society of America, five from the American Institute of Mining Engineers and five from the American Mining Congress, and be appointed by these organizations. Such committee to have the power to select its own chairman and secretary and to add to its membership not to exceed 10 additional mining men or others interested in the subject for which the committee is created. The work of this committee shall be to further the interests of the mining industry through congressional action in accordance with the resolutions adopted at this conference; and its joint report shall be presented to each of the societies formally represented in its make-up.

There was a lively discussion upon the recommendation that one member of the proposed commission should be a representative of the Department of the Interior. Ravenel Macbeth, speaking for the Idaho State Mining Association, was violently opposed to this, saying that Idaho did not want any bureaucratic interference with the mining industry; that it had already had enough of it. Mr. Macbeth was supported by E. Percy Smith, of Wallace, Idaho. The other side was taken by J. Parke Channing, of New York, and by E. B. Kirby, of Missouri. Frank A. Ross, of Spokane, Wash., supported the views expressed by Mr. Channing and Mr. Kirby. When put to vote, the recommendation of the committee on resolutions was upheld by a large majority.

In the evening session the chair was taken by W. R. Ingalls, president of the Mining and Metallurgical Society of America. The first speaker was Horace V. Winchell, who delivered an exhaustive and scholarly address on the subject of ore deposits and the inapplicability of the extralateral law to many of them. He pointed out, moreover, many other failures of the law of 1872. Hon. Charles S. Thomas, United States Senator from Colorado, then made a brief but pertinent address from the standpoint of the mining lawyer, but one who is thoroughly in accord with the purpose sought by this meeting. In conclusion Senator Walsh of Montana delivered a carefully prepared speech in support of the need of revision of the mining laws on even broader grounds than the mischief of the law of the apex and the prerequisite of discoveries where honest discoveries cannot be made.

Editorials

Revision of the Mining Laws

The convention, or conference, of mining men that was held in Washington on Dec. 16 under the auspices of the Mining and Metallurgical Society of America was a noteworthy event, especially for its exhibition that all of the mining organizations of the country—both national and state—could and would unite for a common purpose; next for the unanimity of opinion respecting the particular object of the meeting that was displayed; and finally for the effectiveness that the meeting promises to have. The hall in which the several sessions were held was so commodious that the attendance did not appear to be so large as it really was. Yet it was really remarkable that so many mining men came to it from distant parts of the country. As the reports are carried home the after-effects will become even more important than the immediate ones. The debates in the Washington meeting were less spirited than they would have been if there were less unanimity of opinion.

It is known now, beyond peradventure, that the men engaged in the mining industry in the public-land states want the mining laws revised and codified as a whole; that they want this to be done by Congress upon recommendations by a competent commission after thorough study of the subject. These points were embodied in resolutions offered by the Mining and Metallurgical Society of America. The American Institute of Mining Engineers had previously adopted the same resolutions. The American Mining Congress had formally expressed itself to similar effect. The resolutions had also been officially approved by several state mining societies.

It was made clear, moreover, that the mining men of the United States in great majority want abolition of the law of the apex and of the law making discovery a prerequisite to location. Many of the state mining societies had also followed the Mining and Metallurgical Society in those particulars, but the council of the latter had decided not to press its own action in those matters, regarding it as being incompatible with the major purpose; that is, the securing of a commission to revise and codify the mining laws as a whole. It was not deemed fitting to ask for such a commission and say in advance what it was expected to do. The expressions of opinion on these subjects that have previously been made will surely have great weight, however, in the minds of any commission that may be appointed.

The bills that have already been introduced in Congress by Senator Smoot of Utah (Senate, 52) and Mr. Taylor, of Colorado (H. R. 18), crystallize the issue. Both of these bills provide for the preparation of a tentative code of laws governing mining lands and rights by a commission to be appointed by the President, but they differ in important particulars. Senator Smoot's bill provides for a paid commission of three members, "two of whom shall be lawyers of large experience in the practice of mining law and one a mining engineer who shall have had practical experience in the operation of mines," and the scope of the commission is unrestricted. Mr. Taylor's bill provides for an unpaid commission of five members, "who shall be selected because of their recognized experience in, or knowledge of, the mining industry and mining law;" and the laws relating to coal, oil, phosphate and potash lands are excluded from their consideration.

Both Senator Smoot and Mr. Taylor said frankly that certain of their provisions were framed out of considerations of policy and did not necessarily exemplify their personal views. Therefore criticism of these points may be made without any fear of hurting the feelings of their sponsors. Indeed, Senator Smoot declared from the platform that his chief desire was to have revision, and that no controversy over the way of going about it should be permitted to defeat the purpose. He was of the opinion, however, that the Government of the United States should not make it impossible for any man to serve upon such a commission owing to inability to give the time to do so; nor should it ask of any citizen such a favor as the gift of his time. Mr. Taylor, on the other hand, is of the opinion that the House of Representatives will not agree to a paid commission. However, both his bill and Senator Smoot's provide for $25,000 for expenses in the aggregate. Senator Smoot would have the commission draw $18,000 in salaries, leaving $7,000 for traveling, clerical and printing expenses, etc., while Mr. Taylor would have $25,000 available for those purposes.

With regard to the composition of the commission, Senator Smoot provides for a membership of three, two of them mining lawyers, which he said was in conformity with the ideas of Senator Walsh, chairman of the Senate's Committee on Mines and Mining, while Mr. Taylor would simply have five mining men.

These subjects and others were debated in the Washington meeting. The committee on resolutions made the recommendations that the commission should consist of five members, of whom one should be a mining lawyer, one a representative of the Department of the Interior and three men experienced in mining. As to remuneration the committee was of the opinion that whatever Congress could agree upon would be satisfactory to the mining industry, or at least that difference in ideas over that matter should not stand in the way of action. This report was adopted by a large majority, although there was dissent by the Idaho delegates respecting representation of the Department of the Interior. The action of the convention in these matters was broad-minded and rational, whatever might be the individual views.

On one matter neither the committee on resolutions nor the convention as a whole expressed itself so clearly as it might have done, namely, the question of the scope of the commission. It had previously been pointed out in discussion that the exclusion of coal lands and phosphate lands would create uncertainty and dispute with respect to cases where coal and phosphate rock occur in

connection with metalliferous minerals, while moreover, it is illogical—and probably not intended—to exclude potash deposits and not to exclude soda deposits. The convention confined itself to the opinion that the mining laws should be revised in whole, wherefore, it is to be deduced that the review by the commission should comprise all sorts of mineral deposits—iron, copper, coal, oil, alkali and everything—but this opinion was not clearly defined.

Speaking for itself, the *Journal* is of the opinion that Mr. Taylor's bill is a better bill than Senator Smoot's. It provides for a commission of five mining men. If the men engaged in the mining industry should speak out without any considerations of politics, diplomacy and the getting of what they want by giving up something different, we think they would say that this is purely a mining question. Let it be attended to by mining men. They can employ lawyers for the legal advice that is necessary. With the commission recommended by Mr. Taylor, we should probably get a better piece of work than by the commission recommended by Senator Smoot. The most objectionable part of Mr. Taylor's bill is the exclusion of coal, phosphate, oil and potash lands from general mining-law revision. Such exclusion is in deference to the Administration, which has another program with regard to those lands. If such exclusion there must be, the language that effects it ought to be carefully considered. We know of gold placer deposits occurring above coal seams, of gold occurring with alunite (a potash mineral), and of mines that are worked both for metals and for apatite (a phosphate mineral). One of the greatest mining litigations in this country, one that was longer drawn out than any of the apex cases and was more costly than most of them—we refer to the Franklin Furnace litigation in New Jersey—arose from the deeding of one kind of mineral to one man and another kind to another man, both occurring in the same vein. The Administration and Congress ought to be exceedingly careful about excluding certain kinds of mineral deposits from a general revision of the laws.

Villa Gives Up the Fight

Villa's admission that he is beaten and his proposal to seek refuge in the United States is the most hopeful thing for Mexico that has happened in many years. Heretofore as soon as any patriot has succeeded in casting out the usurper, one of his followers has risen to repeat the process. So it was with Villa, but instead of carrying on the thing indefinitely, he gives in at last and lets his country have a chance for peace. In so doing, he will make a greater name for himself in history than he would as a bandit. Already he gets such recognition as this from the *Evening Post:*

> Villa's acknowledgment that the game is up is formal recognition of a fact that has been patent for some months. It marks the end of an epoch and the beginning of another which will be signalized with due pomp when Carranza enters Mexico City and sets to work at the reconstruction of Mexico with the good will of the nations. For the moment our interest attaches to the flitting from the contemporary stage of one of its most picturesque characters. "Pancho" Villa, the outlaw, who came within striking distance of the Presidency of Mexico, the bandit who developed into a military genius, represented in his own person the raw capacities of the Mexican people for good and evil. He was the peon to whom the policies of Diaz denied the opportunity for developing into a contented and prosperous citizen of his country. It has been a romantic career. Yuan Shi-Kai, who has won an emperor's crown, set out from the high position of governor of one of China's greatest provinces, and has traversed the interval in 15 years. If we measure the distance from Villa's starting point to where he stood at the height of his power, the record is no less impressive. Nor does the picturesque record suffer from the fact that the outlaw Villa rose to fame on the crest of a great cause, that he will go down in history as one of the avengers of Francisco Madero and a vindicator of the cause of Mexican democracy.

In this there is a good deal of truth, although we have some doubts about the "cause of Mexican democracy." However, the great thing is the prospect that warfare in worn-out Mexico, is ended, in spite of the unregeneration of Zapata and the silly plotting of Felix Diaz. Let us hope that Don Venustiano will be reasonable in his decrees and will not tax the miners more than they can bear or compel the bankers to redeem their current notes with gold before they have any gold to do it with. American mining men are already hurrying back to Mexico, and without any doubt they will soon be active in their operations.

Tungsten and Molybdenum

One of the most spectacular advances in commodity prices occasioned by the war has been in tungsten, both metal and ore. This has been due to the extraordinary demand for tungsten steel—an essential constituent in making high-speed tool steel. The manufacture of immense quantities of military material has required greatly increased quantities of tool steel, and consequently corresponding quantities of tungsten: hence the advance in price for it.

Before the war high-speed tool steel was worth about 70c. per lb., tungsten about 60c. per lb. and tungsten ore about $6 per unit. At present high-speed tool steel fetches about $3 per lb., tungsten about $5 per lb. and tungsten ore about $50 per unit. Even at the enhanced prices supplies are scarce.

The fabulous price for tungsten ore has stimulated prospecting for it throughout North America and South America. This ore is not known to occur in large deposits. The annual production of concentrated ore in the United States previous to the war was only about 1,400 tons. However, this ore has now become so valuable that the discovery of a deposit that affords a single carload is the finding of a fortune. A ton of ore assaying 60% tungsten trioxide—the standard commercial grade—at $50 per unit is worth $3,000: a carload of 40 tons would be $120,000. So precious is this ore that the assay offices are being scoured for specimens. Brokers do not sneer at trade in one-pound lots. The purchasing agent of the Crucible Steel Co. is very grateful if somebody can give him 100 lb.

A contributory factor in the production of this situation was the utter stupidity of the British authorities. They fought the advance from the beginning. When they were offered some tungsten ore, they came back with a lower bid—trying to dicker in what was not a dickering market—and naturally failed to get what they wanted. Then they practically commandeered the supply of tungsten ore in the British Empire, appointing official brokers and fixing a price of 55s. per unit, or about $800 per 2,000 lb. of 60% ore if exchange be figured at 4.86. Previous to the war that would have been regarded as a fine price, but the producer in Australia, Burma, Malaya and elsewhere does not think very much

of it when the same grade of ore is fetching $3,000 or so per ton in America. Patriotism does not go quite so far as that. His policy appears to be to restrict production until such time as the authorities may raise the price, which he believes they will have to do. In so forecasting the future he is a better economist, we are inclined to think than is the bureaucrat in London.

In the meanwhile there is relief immediately at hand if the manufacturers of tool steel would only avail themselves of it. We mean the substitution of molybdenum steel for tungsten steel. It is well known that molybdenum steel has excellent qualities of more or less the same character as tungsten steel. There is an extensive literature on this subject to which the tool-steel maker may refer. It is indeed claimed by some authorities that molybdenum steel is superior in certain respects to tungsten steel. The chronic reluctance of manufacturers to get out of the beaten tracks is offered as an explanation of their blindness to the merits of molybdenum steel. But even if it were not preferable with tungsten at 60c. per lb., it might be when that metal is more than eight times as high.

The point is that molybdenum ore and the products thereof are now a drug in the market. While the tungsten mines are being worked at the limit of their capacity, the molybdenum mines have had to be closed, and the smelters of molybdenum ore are carrying large unsold stocks of the products that probably they would be glad to sell at cost. The manufacturers of tool steel and the British authorities are recommended to give some attention to this situation.

⁂

According to an evidently inspired article in one of the financial papers, the Alaska Gold Mines Co. is going to stop increasing the tonnage sent to the mill at the expense of grade of the ore and for a while will make tonnage secondary to a grading of the ore. By February it is hoped to have the mill running on $1.50 ore. The delivery of the ore to the mill will be increased later as rapidly as the development of the mine will permit it. The experience of the Alaska Gold Mines Co. is another example of the principle that the opening of a mine so as easily to furnish 10,000 tons of ore daily is more of a job than the building of a mill to treat it.

BY THE WAY

An unusual consignment of gold from China was received recently at the Assay Office in New York City, says the New York *Times*, consisting of a single bar of fine gold worth about $600 in a bamboo covering. It came from the agency of the Guaranty Trust Co. in Shanghai and was credited to that institution. The hollow of a length of bamboo was utilized as a natural safety carrier for the 4-in. bar, one end being sealed by the joint and the other with wax. The valuable package came by registered mail. There have been numerous shipments of gold from China to this country this year, but most of them have been directed to the San Francisco Mint.

⁂

Roland was green but willing. His resolve to "follow mining" led him to Colorado, where he obtained a job as assistant to a deputy mineral surveyor. The first day out he was informed that the work immediately in hand was to "tie" certain indicated tunnels and assessment pits to a mineral-monument base line. Whereupon he gazed mournfully up toward the summit of Republican Mountain and then toward the village of Silver Plume, meanwhile fumbling a ball of plumb-bob twine that he fished out of the kit, remarking, "Then I better hurry down to the store, hadn't I?" "What for?" inquired his employer. "Well," rejoined Roland, "it will take a damned sight more string than I can find in this bag."

⁂

The safety-first movement has reached the stage of education through slogans, says the Boston *News Bureau*. Safety-first literature teems with them. The walls of workshops are covered with them. Among the following, drawn from the Inland Steel Co. and other sources, employers might select an assortment:

Keep out of debt and danger. Both are alluring, yet poor friends to make.

Peace, prosperity and good health depend on the selection and proper preparation of normal food material.

The difference between a wise man and a fool is the fool's mistakes never teach him anything.

The thinker will not drink. The drinker cannot think.

Any fool can take a chance. It takes brains to be careful.

It takes only a moment of carelessness to cause a lifetime of suffering.

When hurry interferes with safety, cut out the hurry.

⁂

Two powerful American trench-digging machines, says the *Scientific American*, have been in operation for some time at the Canadian camps, where men who will ultimately be sent to the fighting front are being trained. These men are already thoroughly acquainted with life in the trenches, but the trenches have been dug for them by the American machinery referred to, thus relieving them of the hard shovel-work. This innovation was originated by General Sam Hughes, commandant of the Canadian militia, and has proved to be quite successful. At one of the camps two of these machines dug seven miles of trench, 5½ ft. deep, with a 2-ft. bottom, in 10 days. They are readily moved about under their own power and dig trenches of any reasonable depth or width with straight or sloping sides.

⁂

Many contradictory tales have been heard concerning the unobtrusive woman who, in 1885, discovered the principle of oil flotation, in Denver. Since her invention has attained fame, technical men have sought to establish her identity and to give her proper recognition. Recently such efforts—especially those of Howard C. Parmelee, secretary of the Colorado Scientific Society—have brought tangible returns, and it is now established that this lady was not a spinster school teacher, as commonly stated, but the wife of a practicing physician. Her full married name was Carrie Jane Everson, and she occasionally undertook nursing cases in her husband's practice. Since the discovery that she was the wife of a scientific man, it has been assumed that the doctor was largely responsible for the flotation invention, but a telegram received in Denver recently from the son, John L. Everson, of San Anselmo, Calif., reads: "Mother alone invented flotation process. Father assisted in securing patents." While the application of this process has been world-wide, Colorado is coming in for such pronounced benefits from it that there exists a local desire to perpetuate the name of Mrs. Everson.

PERSONALS

J. R. Finlay has returned from Missouri.

B. B. Thayer has returned from Montana.

The offices of Philipp Brothers are now at No. 29 Broadway, New York.

Kirby Thomas, of New York, is examining mines in the Casa Grande district in Arizona.

L. L. Middlecamp superintendent of the Ellamar Mining Co., Alaska, is in the States for the holidays.

H. A. Guess has returned to New York after an extended visit to the Braden and Chiquicamata mines in Chile.

Richard Roelofs, general manager Cresson mine, Cripple Creek, Colo., has returned there from Oatman, Arizona.

J. W. McKim, formerly of Salt Lake City, but for some years back in the Transvaal, has arrived in San Francisco.

W. L. Cumings, of the Bethlehem Steel Co., has returned to South Bethlehem after spending four months in Chile and Peru.

E. A. Cappelen-Smith has been elected a director of the Chile Copper Co. and the Chile Exploration Co. He has gone to Chile.

W. R. Van Evera consulting engineer for the Hill Mines Co. on the Cuyuna Range, has returned to Virginia, Minn., after a visit to New York.

S. D. Bridge, who for the past 26 years has been interested in mining in Mexico, returned to Monterey Dec. 11 after an absence of over two years.

J. H. Plummer, president of the Dominion Steel Corporation, who has had a severe attack of illness, has recovered sufficiently to attend to business.

J. Norman Sherer, of Bellefonte, Penn., has been made superintendent of the blast furnaces of the Reading Iron Co., Reading, succeeding Albert Broden.

L. W. Trumbull is now in the oil fields of southern Illinois. He will be at the Raleigh, Washington, D. C., during the meeting of the Geological Society of America.

Alfred B. Iles, of the Alaska Copper Corporation and Iles Power, Water and Light Co., is in the States on his vacation. He is located at Strelna on the Copper River Ry. in Alaska.

Charles A. Sulzer has taken over the lease of the Alaska Industrial Co. at Sulzer and in future will handle the mine personally. This copper mine has been a continuous producer for 14 years.

Charles Andrews, a well known prospector has returned to Winnipeg from the Gold Lake district where he made important discoveries and staked a number of claims for the Harris syndicate of Winnipeg.

Col. Thomas Cantley, president of the Nova Scotia Steel and Coal Co., who has been prominent in connection with the work of the Canadian Shell Committee, will shortly leave for England and will probably make a six months' stay.

Frederick Peiter has severed his connection as coke oven engineer with the Gas Machinery Co., Cleveland, Ohio. For the past three years he has been engaged in the designing and development of the company's top burner regenerative coke oven.

Among the western mining men attending the conference on revision of the mining laws at Washington on Dec. 16 were George A. Collins, of Denver; John Kirchen, of Tonopah; E. Percy Smith and Ravenel Macbeth of Wallace, Idaho, and S. W. Mudd, of Los Angeles.

Lorne A. Campbell has been appointed Minister of Mines in the newly formed administration of British Columbia. He is one of the leading business men of the interior of the province and has had a wide practical experience in connection with mining and power development.

Henry M. Payne, left London on Dec. 11, on his way to Petrograd, where he expected to arrive about Dec. 20. He will attend further sittings of the Committee of Technical Experts to the Lena-Lenskoie controversy, and expects to return to London and sail for America in January.

Charles E. Duncan, who has been superintendent of the old Cambria works at Johnstown, Penn., has been appointed general superintendent of the Donner Steel Co. and has entered upon his duties at Buffalo. He went to Johnstown from the Carnegie Steel Co. and previously had been superintendent of the Algoma Steel Co. plant at Sault Ste. Marie.

Secretary Lane has ordered the transfer of R. B. Marshall, chief geographer of the Geological Survey, to the position of superintendent of the National Parks, effective at once, and to continue during the balance of the fiscal year. Sheldon Tatum has been designated acting chief geographer, and he will continue to serve as geographer in charge of the Rocky Mountain Division.

W. L. Smith, manager of the Mountain King Mining Co., Valdez, Alaska, went to the property with a companion late in October to inspect workings. His companion returned a few days afterward and Smith was expected to follow in five days. On Nov. 17, three weeks later, nothing had been heard of him and searching parties are now looking for him.

OBITUARY

Frank Howard Bailie died in Pittsburgh, Penn., Dec. 14 aged 44 years. He was born in Freeport, Penn., but spent most of his life in Pittsburgh. He had been for 27 years past connected with the H. K. Porter Co., of which concern he was assistant sales manager at the time of his death. He leaves a widow and one son.

Sidney E. Bennett died in Denver, Colo., Dec. 11, aged 33 years. He was graduated from Colorado College and in 1903 established offices in Denver. He was born in Brookfield, Mo., but went to Colorado when a young man. He was widely known among mining men in that state and throughout the Rocky Mountain region, in which he traveled extensively. For several years he represented the Hill Publishing Co. in Colorado.

Abraham Overholt Tinstman died at Turtle Creek, Penn., Dec. 14, aged 81 years. Born and brought up at Broad Ford, Penn., he was one of the first to enter into the coke business in the Connellsville region 50 years ago. He was a partner with Henry Frick in starting in the coke business at Broad Ford and Mt. Pleasant, and later he organized the Connellsville Coal and Iron Co. He continued in the coke business until a few years ago when he retired.

Richard Henry Lee died at Lebanon, Penn., Dec. 8, aged 56 years. He was born in Pennsylvania and graduated from Lehigh University. Soon afterward his father put him in charge of the cold-blast charcoal furnaces of the Logan Iron and Steel Co., at Burnham, Penn., where he remained for six years. Later he was in charge of blast furnaces for the Colorado Fuel and Iron Co., the Tennessee Coal, Iron and Railroad Co., the Alabama Steel and Iron Co., the Lackawanna Steel Co., and the Shenandoah Iron Co. For three years past he had been superintendent of Lebanon furnaces of the Pennsylvania Steel Co., and consulting engineer for Dunbar Furnace of the American Manganese Manufacturing Co. He was a close student of blast-furnace operations and a successful experimenter, solving many problems in the management of the blast furnace. He was noted for his kindness, especially to younger men, and made many warm friends among his associates. He was a member of the American Institute of Mining Engineers, the American Iron and Steel Institute and the Engineers' Society of Western Pennsylvania. He contributed many valuable papers to the technical press and to the "Transactions" of the Institute of Mining Engineers. He leaves a widow and one son.

SOCIETIES

Teknik Club meeting, Denver, Dec. 14, was addressed by J. M. Simpson on "The Calcination of Zinc Carbonate," and by H. B. Barnes on "Excessive Costs of Caring for Mental Defectives."

Society of Chemical Industry—The regular meeting of the New York section was a joint meeting with the Chemists' Club held at Rumford Hall, New York. The evening was devoted to a lecture on "The Production of Radium from Carnotite," by Dr. Charles L. Parsons, of the Bureau of Mines, Washington, in which he gave an account of the plant which has been erected in Denver, for this work.

Colorado School of Mines has begun the publication of a monthly press bulletin, containing items of interest to the readers of mining publications. During the president's visit to San Francisco he arranged for the purchase of numerous new pieces of equipment for the school's ore-testing plant, including a 10-ton Oliver continuous filter. A Flowers viscosimeter for testing flotation oils has also been purchased.

Geological Society of America—The annual meeting of this society will be held jointly with the Association of American Geographers in Washington, Dec. 28-Jan. 1. Dr. T W

Vaughan, of the Geological Survey, is chairman of the committee on arrangements. A. H. Brooks, F. L. Ransome and P. S. Smith are chairman of subcommittees under Dr. Vaughan. This committee has gone to a considerable amount of work to arrange for a successful meeting.

University of Idaho—The School of Mines will offer during the months of January and February, 1916, a short course for prospectors, miners and millmen. The subjects treated will include prospecting, mineralogy, mining geology, mining, metallurgy, ore dressing and concentration, and milling. There are no fees in connection with any of these courses, and instruction is free. The work is laid out especially for mature men who desire to make the most of their time during this brief period.

Iron and Steel Institute—A circular from the London office says that the Council announces that the annual meeting has been fixed to take place on May 4 and 5, and the autumn meeting on Sept. 21 and 22, 1916. Both meetings will be held at the rooms of the Institution of Civil Engineers, Great George St., Westminster, London. Sir William Beardmore will be inducted into the chair as the new President of the Institute, in succession to Dr. Adolphe Greiner. The Bessemer Gold Medal for 1916 will be presented to F. W. Harbord, honorary consulting metallurgist to the Ministry of Munitions. It has been decided not to hold an annual dinner next year.

Colorado Scientific Society held its regular monthly meeting Dec. 4. The attendance and interest in the society is better this fall and winter than it has been for several years past. Prof. Herman Fleck, of the chemistry department, Colorado School of Mines, read a paper on "Molybdenum," this being the second in a series of four lectures on rare metals to be delivered by him this season. He covered the technology and development of this metal. The series will be eventually published as a bulletin. This was the meeting at which nominations for officers were made and the following were duly nominated for 1916: President, Howard C. Parmelee; first vice-president, Thomas B. Stearns; second vice-president, Frank E. Shepard; treasurer, John W. Richards; secretary, Arthur J. Hoskin. S. A. Ionides and Victor G. Hills were nominated on the executive committee.

University of Illinois—To extend and strengthen the field of its graduate work in engineering, the University of Illinois has since 1907 maintained 10 research fellowships in the Engineering Experiment Station. These fellowships, for each of which there is an annual stipend of $500, are open to graduates of approved American and foreign universities and technical schools. Appointments to these fellowships are made and must be accepted for two consecutive collegiate years, at the expiration of which period, if all requirements have been met, the master's degree will be granted. Not more than half of the time of the research fellows is required in connection with the work of the department to which they are assigned, the remainder of the time being available for graduate study. Nominations to fellowships, accompanied by assignments to special departments of the Engineering Experiment Station, are made from applications received by the director of the Station each year not later than Feb. 1. These nominations are made within the month of February by the station staff, subject to the approval of the faculty of the Graduate School and the president of the University. Appointments are made in March, and they take effect the first day of the following September. Vacancies may be filled by similar nominations and appointments at other times. Nominations to these fellowships are based upon the character, scholastic attainments, and promise of success in the principal line of study or research to which the candidate proposes to devote himself. Preference is given those applicants who have had some practical engineering experience following their undergraduate work. The Engineering Experiment Station, an organization within the College of Engineering, was established in 1903 for the purpose of carrying on investigations in the various branches of engineering, and for the study of problems of importance to engineers and to the manufacturing and industrial interests of the State. Research work may be undertaken in architecture, architectural engineering, chemistry, civil engineering, electrical engineering, mechanical engineering, mining engineering, municipal and sanitary engineering, physics, railway engineering, and in theoretical and applied mechanics. The work of the Station is closely related to that of the College of Engineering, and the heads of departments in the College constitute the administrative station Staff. Investigations are carried on by the members of the staff and other members of the instructional force of the College of Engineering, by special investigators employed by the Station, and by the Research Fellows. By action of the Board of Trustees on Mar. 9, 1915, four additional research fellowships were created in the Engineering Experiment Station, making 14 in all.

INDUSTRIAL NEWS

Among the orders recently booked by the National Transit Pump and Machine Co. is one for three of its new type of Diesel oil engines. These are to be installed in the Joplin zinc district and will be an innovation in prime movers in that field. The Flannery Zinc Co. of Sareoxie, Mo., will use a 200-hp. Diesel oil engine to drive its mill. Another of 150 hp. is to be direct-connected to a Sullivan air compressor. A third engine and pump are to be used in dewatering its mines and will be the first Diesel engine pumping unit to be installed in the Joplin district. The pump barrels will be 30 ft. below the surface while engine and pump will be above ground, a new method of installation in which the National Transit people are the pioneers.

The Diamond Power Specialty Co., manufacturer of Diamond soot blowers to suit every type of boiler, has announced an interesting prize article contest for the four best articles submitted on the subject of mechanical soot blowers. One hundred dollars in gold will be distributed, divided as follows: First prize, $50; second, $25; third, $15; fourth, $10. The contest is open to all consulting and operating engineers and to engineers-in-charge. Articles must be written on one of the following subjects: (A) What the mechanical soot blower has done toward greater economy and efficiency in the power plant; (B) The mechanical soot blower versus the hand method; (C) Why I indorse the use of mechanical soot blowers; (D) Why I have changed my attitude in favor of mechanical soot blowers. Only one article will be accepted from each contestant. No article less than 1,000 words in length will be accepted and articles should not be more than 5,000 words in length. Articles must be in the hands of the Diamond Power Specialty Co., Detroit, on or before Mar. 1, 1916. Articles must be written in ink, or typewritten, on one side of an 8½x11-in. sheet, or near this size. The Diamond Power Specialty Co. reserves the right to use any of the manuscripts in any way it chooses. The first four prize-winning articles will be published. No article accepted for competition unless proper entry is made before the article is submitted. Articles should be sent rolled or flat, not folded. Entry blanks and further particulars may be had by addressing the Prize Article Contest Department, care of Diamond Power Specialty Co., Detroit, Mich. Names of the prize winners will be announced in this publication.

NEW PATENTS

United States patent specifications listed below may be obtained from "The Engineering and Mining Journal" at 25c. each. British patents are supplied at 40c. each.

ALLOY—Metal Alloy of Iron, Cobalt and Manganese. Richard H. Patch, Philadelphia, Penn. (U. S. No. 1,162,186; Nov. 30, 1915.)

ALLOY of Copper, Nickel, Vanadium, Spelter, Tin and Aluminum. Charles Ramsden Denton, Sheffield, England. (U. S. No. 1,162,226; Nov. 30, 1915.)

BLAST-FURNACE SLAGS—Improvements in the Utilization of Blast-Furnace Slag and in the Recovery of Product Therefrom. T. Twynam, Redcar, Yorks., Eng. (Brit. No. 20,258 of 1914.)

CONCENTRATORS—Head-Motion for Concentrators. John F. Isbell, Los Angeles, Calif., assignor to Orren Allen, Denver, Colo. (U. S. No. 1,163,345; Dec. 7, 1915.)

DRILL-ROD EXTRACTOR. William Schildwachter, Walworth, Neb. (U. S. No. 1,163,560; Dec. 7, 1915.)

DRILLS—Improvements in Power-Driven Rock Drills. M. Kellow, Penrhyndeudraeth, North Wales. (Brit. No. 11,564 of 1915.)

ELECTRIC FURNACE. Carl Hering, Philadelphia, Penn. (U. S. No. 1,162,773; Dec. 7, 1915.)

ELECTRIC FURNACE. James M. Lohr and Horace W. Gillett, Ithaca, N. Y. (U. S. Nos. 1,162,178 and 1,162,179; Nov. 30, 1915.)

FUEL—Powdered-Fuel Feeder. Walter L. Caven, Cincinnati, Ohio, assignor of one-half to Walter Macleod, Cincinnati, Ohio. (U. S. No. 1,162,221; Nov. 30, 1915.)

FURNACE—Ore Furnace. Howard F. Wierum, Upper Montclair, N. J. (U. S. No. 1,162,894; Dec. 7, 1915.)

HEAT-INSULATING MATERIAL. Clarence P. Byrnes, Sewickley, Penn. (U. S. No. 1,162,450; Nov. 30, 1915.)

HOISTING—Locking Device for Hoisting Apparatus. William Rutan, New York, N. Y., assignor to Gillis & Geoghegan, New York, N. Y., a Firm. (U. S. No. 1,163,176; Dec. 7, 1915.)

LEACHING—Process of Treating Metallic Ores. Axel Estelle, Hagen, Westphalia, Germany. (U. S. No. 1,162,150; Nov. 30, 1915.)

MAGNETIC SEPARATION—Improvements in Magnetic Separation. Stephan Bruck, Charlottenberg, Germany. (Brit. No. 20,551 of 1914.)

Editorial Correspondence

SAN FRANCISCO—Dec. 15

Modoc County Miners are showing a persistence that should be rewarded. The Sunshine and the Modoc mines in Highgrade district have laid in winter supplies and are determined to proceed with development and extraction of shipping ore during the winter. Several other companies are getting their affairs in shape to resume active operation next spring. The miner who has faith enough in his mine to lay in a supply of provisions and material to keep his property going through a winter in Modoc county, is entitled to large returns on the investment of money and energy. Besides the operation in Highgrade district there is very little mining being carried on in Modoc county. When the district was first opened up three or four years ago a boom was started which was not warranted and which gave the camp a black eye and discouraged a number of investors who otherwise would have been of value to the camp. But some men who were pioneers in Highgrade are sticking to it with determination.

Amador County Merchants are proposing a bond issue of $250,000 for good roads. The county is paying out from $20,000 to $25,000 a year on roads, and as this amount would be sufficient to meet the interest on the bond issue, and provide for sinking fund, the bond plan would provide the needed highways without increase of taxes. The matter was considered at a meeting of the merchants at Plymouth and the recomendation was made by a former chairman of the board of supervisors. All the merchants present indorsed the plan and it is believed that the bond issue will be voted upon early in 1916. The annual payroll of the mines and other industries in Amador County amounts to $1,250,000. The transportation facilities are chiefly confined to the Amador Central Ry. running between Ione and Martell. This road is not available to all parts of the county, and supplies for the mines must be taken in by way of Ione or Latrobe and wagon-hauled to the mines. In some cases motor trucks are used. But the roads are not in good order for either motor trucks or wagons. With a good highway from Jackson, Sutter Creek, Amador City, Dry Creek and Plymouth, thence to Sacramento the merchants claim their transportation costs could be reduced by moving of water-borne freight from Sacramento by motor trucks. The proposed road work would include 13 mi. to connect with the Sacramento County line at which point connection would be made with the road leaving Sacramento by the way of Slough House. At present there are 15 mi. of this road beyond Walsh station in Sacramento County that would have to be paved before the highway could be completed and ready for use through from Sacramento to Jackson. There is little doubt that Sacramento would do this necessary work as direct haulage from Sacramento to the mines would be an important feature, well worth the expenditure.

BUTTE—Dec. 16

Increased Activity in the Philipsburg District following recent rise in silver is reported. Prominent among developing companies are Mondamin, which during past season has expended for equipment and mining over $22,000. Among leasers, Courtney Bros., operating Coyle property in Hasmark, has successfully exploited silver-lead deposit from which they have made several shipments of pay ore. McLure Bros. operating Sunrise property at Henderson, has recommenced shipment of copper ores from that property. Various leasers on ground of Philipsburg Mining company at the Hobo, Trout and other claims, have shipped cars of ore running as high as 10% copper and others as high as 100 oz. silver. Johnson and Thomas who have a lease on Gold Reef in South Boulder district have installed a cyanide plant that is successfully treating gold ores from that property. Granite Bi-Metallic Consolidated Co. has inaugurated campaign of surface and underground prospecting to disclose any heretofore unknown orebodies. During the last year company's property has been a continuous producer and has shipped over 300 cars of ore of all classes.

DENVER—Dec. 17

Cripple Creek District's Production for December is estimated at 83,550 tons, making year's output 982,697 tons of a gross valuation of $16,135,164. This means an average monthly production of about $1,345,000, which closely tallies with December figure. The lowest production for the year was in January when it was $1,121,884: The highest was in March, $1,986,493. The greatest tonnage in a single month was 92,175 for October.

A Reduction in the Treatment Rates at the two big custom mills at Colorado City—the Portland and the Golden Cycle will be announced soon, it is said. This will lessen the nominal treatment charge on low-grade Cripple Creek ores by $1 per ton, the new rate being $2. Heretofore, milling companies have paid the freight which averages about 50c. per ton; but, under the new terms, the shipper will pay his own freight, so that the proposed change really means a saving to him of about 50c. per ton, while the treatment rate is really lowered only the same amount.

Boulder County's Mineral Statistics for 1915 have been estimated by the Boulder Commercial Association and announcement is made that tungsten leads, by far, in the output of minerals—viewed from the standpoint of value. It is believed the year's production of this kind of ore will be about 1,440 tons with a valuation of $1,687,300. This ore, therefore, would appear to have averaged more than $1,170 per ton. A "dicker" between a miner and a purchaser of this class of ore last week resulted in the closing of a sale of a small lot of high-grade stuff at $60 per unit.

Breckenridge Used to be Famous as a producer of handsome specimens of free gold. Many remarkable pockets were encountered in the early days but not much has been heard of such bodies for a good while. Interest in them has been revived by the recent opening of a bonanza in the Dunkin mine on Nigger Hill, where leasers took out 240 lb. of stuff said to average $6% fine gold beside much second-grade material worth about $1,000 per ton. The pocket will probably show a production of $40,000.

Idaho Springs Shows More Activity than for a decade past. This pretty little mountain city has, recently, been much advertised as a summer and health resort because of its splendid hot and cold springs that are claimed to possess radioactivity. Indications are, however, that mining will again become the leading industry. In the "silver days," this town was lively: With the termination of high prices for silver, there came a slump. Owing to numerous shady mining deals that had disgraced the district, it was difficult, for a long time, to secure the attention of investors to its mineral merits. With interest again centering in the mining industry in general and the near-elimination of questionable financial practices, this district should thrive. Already several projects of significance have been financed. The McClelland Tunnel, started as a crosscut drainage, transportation and development adit toward the Lamartine part of the county and driven in about 1½ miles, has been newly re-financed and operations are about to resume. The Bellevue-Hudson, American Sisters, Boulder Nest, St. James, Tabor, Jo Reynolds and Commodore Tunnel are among other old properties that promise to resume operations in the near future.

SALT LAKE CITY—Dec. 16

Salt Lake Stock and Mining Exchange during November traded in 1,335,668 shares of stock, valued at $349,693; an increase of $109,662 over October. During 11 months of the year there were sold 15,461,931 shares of stock valued at $3,388,875 as compared with 3,387,020 shares valued at $693,472 during 1914.

A Sulphuric-Acid Plant is to be built in Salt Lake valley by the American Smelting and Refining Co. in the near future. The initial capacity is expected to be 100 tons per day, which can be increased as desired. Fumes from the smelters will be utilized. This crystallizes plans which have been under consideration for several years and have included almost every form of smoke consumer and utilizer.

Zinc Shipments continue from the Lakeview mining district on Promontory Point near Ogden. During November, the Lakeview Mining Co. made net earnings of $31,000, from the shipment of 19 cars of zinc ore, including four cars by lessees. This ore averaged 32% zinc. The first work as done in March of this year, and shipments were begun in May, from which time the property has been self supporting, and on a dividend-paying basis. In December eight cars or about 400 tons had been shipped up to the time that the dividend was paid.

WALLACE, IDAHO—Dec. 18

The Mineral Production of Idaho for the year 1914 was $24,976,706, and of this $23,607,604, or about 95% came from the Cœur d'Alene district in Shoshone County. State Mine Inspector Robert N. Bell, who spent several weeks in this district last month, estimates that the production this year will exceed $30,000,000. The large increase implied in his estimate will come largely from Cœur d'Alene mines, probably in about the same proportion as production in 1914. The tonnage for 1915 will probably not show much if any increase, the large increase in value being due to the high prices of lead and spelter. Two of the largest producers, the Hercules and the Morning, were shut down several months during the present year, otherwise there would have been a great increase in tonnage also. The dividend record for Cœur d'Alene mines will be far in excess of any year in the history of the district. Last year the total dividends amounted to $6,042,752 and was the highest record. This year dividends have now been declared amounting to $8,952,429. These figures are from official sources with the exception of the Hercules, which is estimated. The final figures will be in excess of $9,000,000 and possibly $10,000,000. Dividends for December already paid and to be paid before the first of the year amount to $1,377,985. This forecasts a Merry Christmas to many stockholders scattered all over the country and to thousands who receive good wages and steady employment through the operations of the mines.

The Golden Chest, in what is commonly referred to as the gold belt of the Cœur d'Alene district, has been the center of much interest the past few weeks. Many years ago the mine produced considerable gold, but questionable management and litigation long since forced it into idleness. The property has been quite extensively developed and has a 20-stamp mill. The company owns 37 patented claims and valuable water rights. After passing through many legal entanglements, the property is now owned by Samuel Green of New York. Mr. Green was here last week and coincident with his coming also appeared several mining engineers and geologists, all apparently bent upon examining the Golden Chest. There has been more or less mystery about the coming of these experts which time alone will solve. However, one highly interesting fact has been disclosed in connection with this famous old gold mine. In the old days when mining methods were more crude and less attention was given to careful analysis of ores, particularly free gold, much difficulty was experienced in saving the gold in Golden Chest ore on account of the heavy gangue, which was recognized as an unusual substance accompanying the quartz, but which no one appears to have taken the trouble to analyze. It is now learned that this troublesome stuff was scheelite (tungsten) and that it is found in combination with the quartz throughout the Golden Chest vein. Much of it was left in the stopes by the early day miners, while many tons went into the creek as tailings from the mill. At that time tungsten was worth about $300 per ton, while now, thanks to the war, it is worth over $3,000 per ton. This has infused new life into the long abandoned proposition. While Mr. Green was here he started men retimbering and generally repairing the underground works and tungsten ore is now being sacked for shipment. In addition to the tungsten, it is the opinion of capable mining men that under modern methods of mining and milling the Golden Chest may again come back as a gold producer.

BELLEVUE, IDAHO—Dec. 15

The Croesus Gold Mine has been taken over by a Spokane, Wash., group headed by Fred C. Robertson. Possession was given by Kilpatrick Bros., the owners, Dec. 1. This is the property purchased a year ago by Robert T. Tustin and associates, who contemporaneously with its purchase, also purchased the Old Vienna property. The bond was forfeited as to the Croesus, and the forfeit money abandoned, in favor of the Vienna property, on which property a large number of men have been working since early summer. The first car of ore from development, high-grade silver running as high as 1,500 oz. to the ton, is just now being loaded at Ketchum—the nearest railroad point.

The Old Red Elephant Mine, which was in early days one of the bonanza producers of the Bullion District, situated on the opposite side of the diorite flow whose eastern contract produced the famous Minnie Moore, Queen and other bonanzas in the '80s, struck the vein in the 2,600-ft. crosscut driven for the purpose. The pay streak was a few inches over 8 ft. wide—about one-third of the ore being first-class shipping, and the balance the regular grade of old Original Red Elephant mill rock. These ores average 70% lead and 130 oz. of silver. The Company celebrated the "melon" in Chicago last week, by ordering a 100-ton mill erected as soon as possible, together with a complete mining equipment. J. G. Sawyer is to be in charge of the work.

LOVELOCK, NEV.—Dec. 14

An Industrious Little Badger was unconsciously the cause, this week, of the discovery of a new antimony lead at Antelope Springs, about 25 mi. from here, which gives great promise. While digging his hole, the badger threw out small portions of float rich in antimony. J. H. Caustin noticed these specimens while prospecting. He made an investigation which resulted in the uncovering at the grass roots a lead that runs between 50 and 60% antimony. The vein is 5 ft. wide at the surface, and has been uncovered for a distance of 40 ft. Ten tons of this ore was removed in one day.

MORENCI, ARIZ.—Dec. 16

Strikers Held up and Searched two A. & N. M. trains few miles below Clifton last week. Contractors who had agreed to do Arizona Copper Co.'s assessment work were run out of town, although contractors offered wages that the strikers were asking for. If the union does not change its attitude about the assessment work the Detroit and Arizona companies will have 155 mining claims go by default.

LEAD, S. D.—Dec. 18

In the Black Hills, there has been comparatively little activity during the past year—except in tungsten, owing to the phenomenal rise in price of that metal. Several carloads have been shipped by Wasp No. 2 and one by Homestake, the latter being from the old Hidden Fortune ground. Selected high-grade ore as shipped is reported nearly 50% tungsten trioxide, but there is much of lower grade, and the Wasp is installing a concentrator to treat this. The ore is wolframite. No new deposits have been announced. The Wabel property near Hill City was sold during the year. Much prospecting has been done in a small way for other rare elements, but though molybdenum, vanadium, and uranium have all been found in the Hills, no occurrence of commercial importance is known. Changes at the Homestake consist in the remodeling of the B. & M. (or Old Abe) shaft, now equipped with a Nordberg hoist; an Edgemoor boiler plant supplies steam to this and a turbo-generator plant auxiliary to the Spearfish hydroelectric system, some current having hitherto been purchased. The Hanna pumping station has also been electrified. Metallurgical changes—in the direction of increasing the weight of stamps, using heavier heads, and casting mortars with open fronts and backs—have been made. Labor conditions are unchanged. The Homestake, following the practice of the past few years, has announced that a 7% addition to the year's wages will be paid to all employees on the December payroll. Trojan, Golden Reward, and Mogul continue running on the same scale as last year.

HIBBING, MINN.—Dec. 18

Shortage of Labor being keenly felt in this district. At the Bangor and Mohawk mines difficulty was experienced in securing enough men for third shift. Several hundred more men could be given full winter's work here this season. In Virginia District the situation is not so acute. Virginia & Rainy Lake Lumber Co. has established 17 camps, employing upward of 3,000 men, at wage increase of 50% over last season. The various mining companies centering at Virginia will keep 2,000 men at work through the winter, while an equal number are employed at Chisholm. Outlook is that labor costs will keep pace with advanced ore prices for 1916. With the European sources of labor closed, if the prediction of a 55,000,000-ton production is to be realized, it seems that laborer will participate in war profits.

TORONTO—Dec. 18

The King Dodds Vein, the discovery of which occasioned the Kowkash gold rush, has pinched out a few feet below the surface, according to information received at the Ontario Bureau of Mines. The report of Percy E. Hopkins, who investigated the district some weeks since, is stated to be satisfactory especially as regards other veins found further west along the line of the National Transcontinental Railway, but is not being published—as it was considered that sufficient development had not been carried on to permit examination as a basis for determining the extent of the orebodies.

There Is Much Complaining among the mining men of Manitoba as to the operation of the provincial mining law which requires a mining company to be on a dividend-paying basis before stock can be offered to the public. It is asserted that this provision makes it very difficult to secure capital for legitimate development purposes, and that it has the effect of giving the control to American capitalists, who buy up claims at a low price and organize companies in the United States. Prof. Wallace, of Manitoba University, who has been delivering a series of lectures on the gold deposits of the province, has made the suggestion that sales of stock in non-dividend-paying companies should be permitted on the condition that the money so secured should be placed in the hands of trustees, who would see that it was properly expended for the development and equipment of the mines.

The Mining News

ARIZONA

Cochise County

DRAGOON TUNGSTEN (Dragoon)—Arizona's biggest tungsten producer. Shipping 6 tons concentrates daily to reduction works at Rochester, N. Y.

Mohave County

ORPHAN (Secret Pass)—O. T. James is milling about 1 ton every 8 hr. with 2-stamp mill and is saving $10 per hour.

LEVIATHAN COPPER (Cedar)—Has shaft down 200 ft. and has opened up large deposits of ore, carrying copper and molybdenum.

AMERICAN MOLYBDENUM (Cedar)—Company has built oil flotation and concentration plant of about 25 tons capacity for experimentation purposes. Ore assaying from 2% to 25% in molybdenum has been found in shaft on 12-ft. ledge.

UNION BASIN (Golconda)—Operating Golconda mine, 20 mi. north of Kingman, has declared $85,000 dividend, second of the same size since present owner, N. L. Amster, of Boston, acquired control, June 1, 1915. Company is building oil flotation plant and an electric power line from Kingman. The main shaft is now 300 ft. deep.

Pima County

CALERO (Twin Buttes)—Green, Adams and Page have bought this mine and have begun to ship 4½% copper ore.

CACILLO (Tucson)—This property, 40 mi. west of Tucson, is reported bonded for $150,000. Julian Johnson has developed mine, hauling ore to Tucson for shipment to El Paso smelter.

MARY JANE (Nogales)—A. D. McGhan is building wagon road to this property, 14 mi. north of Nogales. He intends to drive tunnel into hill, which has several veins of gold, silver and copper on surface.

NEW VENTURE PLACER (Amado Station)—Company is taking out about 100 cu.yd. per day, average $1.25 per yd. Recently installed Clark dry machines. Property is 60 mi. southwest of Tucson and 20 mi. west of Amado. L. C. Friend, manager. Estimated 4,200 acres of gravel, averaging $1 per cu.yd. Papago Indians and Mexicans have known and worked placers for many years.

Yavapai County

MORE LOCATION NOTICES were filed in first 11 months of this year in Yavapai county than in whole of 1914. Up to first of December 1115 notices had been filed as compared with 850 for year 1914. November was record-breaking month exceeding all records since the spring of 1907.

COPPER QUEEN GOLD (Mayer)—Is preparing to resume operations after several months' idleness.

BLACK CHIEF (Prescott)—Plans for refinancing completed; active operations will begin at once. New pumping plant to be installed.

CALIFORNIA

Amador County

KELLY (Jackson)—Tunnel being retimbered at portal and other repairs being made. Property situated about 3 mi. south of Jackson; formerly operated by Owen Kelly. After his death property purchased by Charles Vicini.

JOE DAVIS (Amador City)—William J. McGee, United States subtreasurer, has secured control of property known as North California and Joe Davis Mines. Former directors resigned and following have been elected: W. J. McGee, Ralph McGee, C. R. Downs, Charles Gillis, Emma Parrow. Assessment of 5c. per share levied. Office of company removed to Sutter Creek.

Calaveras County

PIONEER CHIEF (San Andreas)—Three new transformers installed. Development showing good results; day and night shifts being worked. Joseph E. King is superintendent.

TULLOCH (Angels Camp)—Property taken over by Thomas Lane. Was formerly producer; been idle number of years. The 200-ft. shaft will be deepened to 800 ft.

ROBBERS ROOST (Nimshew)—Pay gravel is being worked and company has done large amount of development including construction of reservoir and drain tunnel half-mile long.

Eldorado County

GEORGIA SLIDE (Georgetown)—Property being developed under bond taken by Eastern men, represented by Robert E. Cranston, of San Francisco. Teams and motor-trucks are hauling in supplies. Air compressor and other machinery will be installed.

Inyo County

POWELL'S CAMP west of Randsburg is showing a great deal of activity. Roschl, Lawrence, Watchman, Sanderson and Powell are extracting large amounts of low-grade tungsten ore.

CERRO GORDO (Keeler)—Contract made with Southern Sierras Power Co. for electric power for mine and camp purposes. Transmission by pole line from Keeler.

SKIDOO (Skidoo)—An oil-fired boiler has been installed for heating cyanide solution.

Nevada County

GOLDEN CENTER (Grass Valley)—New hoist put in operation Dec. 1. The 10-stamp mill will be doubled and cyanide plant installed.

UNION (North Bloomfield)—Tunnel will be driven 40 ft. further where it will intersect bottom of old incline shaft that was sunk to gravel channel.

Sierra County

OXFORD-GOLD BLUFF (Downieville)—Aërial tramway being installed to transport ore from Oxford ground to Gold Bluff mill. Both mines operated by Cliff Leasing Co., of Salt Lake City.

TWENTY-ONE (Alleghany)—Following judgment for $25,000 and costs by Federal Court at San Francisco, in favor of U. S. Senator William Flynn, of Pittsburgh, Penn., against officers and stockholders, on charge of selling him "salted" mine, comes information of strike of bonanza ore of same character as that produced by Tightner, Oriental and other famous mines on same serpentine belt. F. M. Phelps in charge of operations.

COLORADO

Summit County

TONOPAH PLACERS (Breckenridge)—Is operating three boats full time.

FRENCH GOLD DREDGING (Breckenridge)—Operating the Reiling boat is making average recovery of $1,300 per day. When digging along south bank many good sized nuggets are found, while few are found on north bank, indicating apparently the chief enrichment came originally from mountains to the south.

IDAHO

Shoshone County

STANLEY (Burke)—Shipped car of gold-antimony ore from near surface. Driving crosscut to gain depth.

NORTHERN LIGHT (Pine Creek via Kingston)—Main shaft will be sunk 200 ft. from 200 level. Lead, zinc and silver have been found in upper levels. B. G. Harmon is manager.

NEVADA-STEWART (Pine Creek via Kingston)—Will be equipped with compressor and drills. Crosscut will be driven to cut vein at depth of 400 ft.

BIG CREEK LEASE (Kellogg)—W. R. Hughes is driving crosscut from Big Creek vein to Polaris vein, which traverses Yankee Boy ground as parallel vein system.

WISCONSIN (Moon Gulch)—Mine has been unwatered to 90-ft. level and crosscut started to vein, supposed to be about 50 ft. from shaft. After driving on this level, will sink to 200.

HIGHLAND-SURPRISE (Kellogg)—Alterations and additions to mill have been completed with exception of flotation plant, which will be completed by first of year, when regular shipments of concentrates will begin. Ore is lead-zinc and mine has large reserve.

NATIONAL (Mullan)—After two weeks try out, National mill now in good working order; running on full time. Was first in district to introduce flotation. New 1,200 level in ore of better grade than levels above. Ore is copper and management is quoted as stating that an average of 1½% will pay, although higher average is expected.

POLARIS (Kellogg)—Polaris Development and Mining Co. organized this week, preparing to begin operations on Polaris taken under bond. Was developed many years ago by drift and shaft 160 ft. deep. Ore is gray copper running high in silver; extensive shipments were made in early days. Three-mile wagon road has been rebuilt, new building erected, and compressor, hoist and pump ordered. Colonel W. E. Mann is in charge.

PATUXENT (Wallace)—Important strike made at depth of 550 ft. Property on Nine Mile joins Rex on north, being explored by crosscut from Rex tunnel No. 2. Vein proved to 50 ft. wide. Along hanging wall there is 6 ft. of lead-zinc ore about equally divided and of good milling grade. Control of Patuxent owned by James F. Callahan, original owner of Callahan mine and largest individual stockholder in Consolidated Interstate-Callahan.

MICHIGAN

Iron

VOLUNTEER (Palmer)—One hundred and fifty men now employed. One hundred and sixty thousand tons of ore sold for 1916 delivery.

ODGERS (Crystal Falls)—Shaft work started two weeks ago. Quicksand encountered at 15 ft. passed through successfully. Ledge struck at 26 ft. Rock drills are now being used. Believed that mine will be in shape for hoisting next summer.

SPEIS (Iron River)—This is name of new Cleveland-Cliffs Iron Co. property. Twelve forties are under option. Two have been leased. Shaft work will start shortly. Sixteen buildings to be erected. Contract has been awarded. Drilling was done three years ago. Good body of ore developed; lies 51 ft. below sand and gravel. Spur line being surveyed.

CLEVELAND-CLIFFS (Ishpeming)—Stockholders at a special meeting just held, authorized an increase in the capital stock from $5,000,000 to $10,000,000 and authorized directors to make disposition of the new stock, which they will do some time this year. Company resumed dividend payments in October after discontinuance about a year, the resumption being on a 10% basis. Stockholders have been notified of plan to issue $3,500,000 of collateral trust 6% bonds to reduce floating indebtedness and provide for future requirements.

MINNESOTA

D. & I. R. RY. (Two Harbors)—An appropriation has been made for the construction of new car and paint shops, 275x310 and 50x184 respectively. The changes are necessitated because of anticipated heavy tonnage of ore next season.

Duluth

CUYUNA-SULTANA (Ironton)—Planned to start stripping operations and construction of concentrator immediately after Jan. 1.

MINNESOTA STEEL (Duluth)—Actual steelmaking has begun at plant; operation thus far being confined to billets. Rail mill is ready for operation but is not being used.

FERRO (Manganese)—A 75x40 boiler house under construction, with space for four boilers. Compressor plant will have capacity for 15 drills. Company reports having contracted for sale of entire 1916 output, planned to be 150,000 tons.

Mesabi Range

HULL-RUST (Hibbing)—This pit produced 2,294,405 tons during past season, being leading producer in Lake Superior district.

MONTANA

Fergus County

BARNES-KING DEVELOPMENT (Kendall)—Estimated returns from 4,206 tons of ore treated at North Moccasin mine during November show $8.51 per ton. At Piegan-Gloster property near Marysville, 2,670 tons of ore treated during November, yielded $4.98 per ton.

Silver Bow County

BUTTE DULUTH (Butte)—Negotiations for sale of property are still going on.

BUTTE-ZENITH CITY (Butte)—Will begin unwatering 670-ft. shaft, and as soon as unwatered it will be sunk to 1,000-ft. level.

BUTTE & SUPERIOR (Butte)—Official estimate of net profits for current year $9,000,000 derived from concentrates approximating 150,000 tons. Working capital on Jan. 1, 1916, after payment of $2,200,000 in dividends, Dec. 31, should amount to $5,000,000.

DAVIS-DALY (Butte)—Annual report of company for year ended June 30, 1915, together with quarterly report for three months ended Sept. 30 of this year just issued. Operating charges for year were $204,455; total income $24,411; excess charges over income $180,043. Unofficial announcement made that receipts from ore for October and November will be between $35,000 and $40,000. Mining costs for these months estimated at less than $15,000. Faulted extension of Hesperus vein has been picked up, insuring addition of large orebody to the company's reserves.

NEVADA

Esmeralda County

GRANDMA (Goldfield)—As result of November annual meeting, it is announced that company will be reorganized for purpose of financing deep development. Ground lies east of Kewanas, north of Spearhead, and contiguous to both.

ATLANTA MINES (Goldfield)—Stoping above 1,580-ft. and 1,620-ft. levels continues to yield small tonnage of shipping ore while exposing considerable tonnage of lower grade ore not amenable to profitable treatment by present local milling facilities.

SANDSTORM-KENDALL (Goldfield)—Winze from long east crosscut on 500-ft. level, started on the vein, passed into foot wall at about 80 ft. and was continued to 200-ft. point where a station was cut. From here an east crosscut has progressed 120 ft. without encountering vein, indicating a decided flattening of vein between 500-ft. and 700-ft. levels.

FLORENCE (Goldfield)—Dumps leased to Nevada Metal Extraction Co., which will erect flotation plant on site of old Florence mill. New 75-ft. headframe is completed and in commission. Drifting is in progress on 250-ft. level for purpose of exploring old Reilly Lease and vicinity, while on 530-ft. level west crosscut will be driven beyond old Rogers-Syndicate lease.

NEVADA METAL EXTRACTION CO. (Goldfield)—Company formed of Nevada mining men for purpose of treating refractory ore by flotation process. Extensive tests on Goldfield base ores resulted in their acquiring three-years' lease on Florence dumps, estimated to contain 50,000 tons. Ground for 150-ton plant being cleared on site of old Florence mill; part of machinery is on ground. Expect to be running in February. F. A. Mead, superintendent.

Humboldt County

ROCHESTER MINES (Rochester)—Mill resumed operations after brief shutdown caused by disabling of freight engine on Nevada Short Line, which transports ore from mine to mill, a distance of about two miles.

Nye County

TONOPAH ORE PRODUCTION for week ended Dec. 11 was 10,114 tons; estimated value, $208,012, compared with 9,747 tons for week previous. Producers were, Tonopah Belmont, 3,133 tons; Tonopah Mining, 2,825; Tonopah Extension, 1,850; Jim Butler, 1,100; West End, 756; Halifax 128; North Star, 50; miscellaneous leases, 212 tons.

NORTH STAR (Tonopah)—In stope above 900 level, ore has narrowed and appears to be approaching cap rock, although considerable tonnage is still available. New stope has been started above 950-ft intermediate level on about 2½ ft. of good ore. Regular development continues on 850 and 1,250 levels.

MIDWAY (Tonopah)—At new shaft on 1,350 level, in drift 50 ft. off main north crosscut, winze has been started on vein. Will be put down to 1,450 level and vein crosscut at that point. Several sets of leasers continue operations in old workings and make frequent shipments of ore.

RESCUE-EULA (Tonopah)—Eula crosscut, projected to crosscut width of Eula claim on 950 level just east of endline of Occidental claim of Belmont company, being advanced about 40 ft. per week. Announced that shaft will be sunk additional 150 ft. to 1,100 level, where lateral work will be started, development continuing meanwhile on 950 level.

Storey County

MEXICAN (Virginia)—Advanced east and west crosscuts No. 2A on 2,500 and 2,700 levels, through porphyry and quartz of low assay value. Mexican mill treated 444 tons custom ore, average assay value $22.01 per ton.

OPHIR (Virginia)—Saved 361 cars of ore from Central tunnel stopes and shipped 320 tons to mill. Exploration continued and prospecting from southwest drift on 2,500 level discontinued. Jointly with Con. Virginia west crosscut on 2,700 level advanced 30 ft., to 141-ft. point through vein porphyry and quartz stringers.

NEW MEXICO

Grant County

ERNESTINE (Mogollon)—Has completed construction of new machine shop; and installation of centrifugal pump at mine.

BURRO MOUNTAIN COPPER (Tyrone)—Capitalization of company has been increased from $200,000 to $8,000,000. Preparations still being made for 1,000-ton mill.

BONNEY (Lordsburg)—John M. Sully, general manager of Chino Copper, Mr. Thorne, of Santa Rita, and F. R. Jones, of Silver City, have closed deal for this property and, it is understood, will begin development on large scale.

Lincoln County

PARSONS MINE (Parsons)—Supt. A. B. Anderson remodeling mill and installing new machinery. Power line will soon be finished and milling is to be started by next March.

Santa Fé County

SANTA FÉ GOLD AND COPPER (San Pedro)—J. H. Wood is working about 300 men and installing extensive machinery.

UTAH

Beaver County

BEAVER GOLD ZONE (Beaver City)—New hoist will be installed at 40-ft. shaft. A. E. Rykert is general manager.

MOSCOW (Milford)—Installation of new electric hoist has been completed, and shaft sinking from 800 to 1,100 level will soon be started.

RED WARRIOR (Milford)—Efforts being made to resume operations at this property near Moscow. Ore has been produced in past, but greater depth is needed.

MAJESTIC (Milford)—Stockholders have received statement from J. M. Dick, of Boston, president of company, giving settlement assays on 19 cars of ore recently shipped from the Old Hickory; these averaged 1½ oz. silver; 3% copper and 36% iron. Net operating profit for November was $2,450. Shaft at Hoosier Boy, being sunk below 400, has reached depth of 600 ft. Two shifts are working.

Juab County

TINTIC SHIPMENTS for week ended Dec. 10 amounted to 134 cars.

IRON BLOSSOM (Silver City)—Copper orebody below 900 is being developed.

Salt Lake County

UTAH COPPER (Bingham)—October production amounted to 16,004,607 lb. copper, which is the high record. Stripping operations being carried on at usual rate; according to D. C. Jackling these will be decreased rapidly within year.

Summit County

PARK CITY SHIPMENTS for week ended Dec. 10 amounted to 3,485,051 lb.; estimated value of $59,000.

SILVER KING CONSOLIDATED (Park City)—Shipments during the first 10 months of year averaged 48.67 oz. silver, and 29.7% lead.

NAILDRIVER (Park City)—Owns claims in eastern part of Park City district; has had its stock listed on Salt Lake exchange. Capitalization is 300,000 shares, par value $2, with 12,550 shares remaining in treasury. There is no indebtedness, and $5,000 cash on hand. W. Mont Ferry is president. Ore carrying silver, lead, copper and gold was shipped during 1903, 1904 and 1905. Six men are working.

Tooele County

BULLION COALITION (Stockton)—Drifting being done on 200 level to cut orebodies opened above Honorine tunnel. Electric pump recently installed; capacity, 600 gal. per min.

CANADA

Ontario

ORE SHIPMENTS OVER THE T. & N. O. RY. for the month of November, 1915. From Cobalt proper; Beaver, 111 tons; Buffalo, 61; Cobalt Comet, 65; Coniagas, 104; Crown Reserve, 101; Kerr Lake, 58; La Rose, 130; McKinley-Darragh, 161; Mining Corporation of Canada, Cobalt Lake, 92, Townsite City, 114; O'Brien, 25; Penn Canadian, 73; Peterson Lake, 130; Temiskaming, 88; from New Liskeard; Casey Cobalt, 42; total silver ore shipments, 1,409 tons; from Porquis Junction, Alexo Mine (nickel), 1,305 tons.

MEXICO

Durango

ESPERANZA (El Oro)—A. C. Savage has left El Paso with several carloads of cyaniding and other mining supplies for El Oro. Esperanza, which has been shut down for several months, is starting up.

The Market Report

Metal Markets

NEW YORK—Dec. 22

The outstanding feature of last week was the sharp advance in th eprice for copper. Lead and tin also advanced. Spelter too was stronger.

Copper, Tin, Lead and Zinc

Copper—About the beginning of our last week of record, domestic manufacturers, especially some who have ammunition contracts, began to exhibit signs of nervousness. The storm of Dec. 13-14 and the disorganization of telephone and telegraph communication throughout New England, and the consequent inability to keep in touch with the market, played a part in this. However, the basic factor was the manner in which numerous manufacturers let themselves go short of the market, having failed to contract for the metal that they needed for their own products already sold. These manufacturers required copper for early delivery and in the first quarter of 1916. When they attempted to cover their shorts they found that copper was not easy to get; they had to hunt for it. One of the largest producers was so well sold ahead that it had none to offer. Another one withdrew from the market pending the negotiation of a spectacular piece of business. With these conditions the price was driven up sharply on business that was in no way extraordinary. Having risen to the level of about 20c., r. t., the market opened at 19.95@20c. on Dec. 20 and closed on that day at 20¼c., r. t. On Dec. 21 the opening was at 20¼c., r. t., and the closing at 20½c., r. t. On Dec. 22 the market opened at 20½c., r. t., and before the end of the day sales were made at 20¾c., r. t., with leading producers then asking 21c., r. t. Sales in England were made at £97½@101½ during the week.

On Dec. 22 was announced the consummation of a spectacular transaction whereby the British government purchased 60,000 long tons of copper from two leading American producing interests for delivery during 1916. The price was in the neighborhood of 20c. This copper was taken for delivery month by month during 1916.

Copper Exports from the United States in the week ended Dec. 4 are reported by the Department of Commerce at 20,332,109 lb.; the larger items being 7,871,554 lb. to France; 6,098,675 lb. to Great Britain; 2,581,374 lb. to Russia and 1,725,041 lb. to Italy. Imports for the week were 104,951 lb. metal and 1,777,888 lb. in ore and matte; 1,882,839 lb. in all, chiefly from Chile and Canada.

Tin—On Dec. 16 the market rose sharply on news that the British government intended to curtail exports until such time as a safe working stock should be accumulated in Great Britain. When it was learned, however, that the idea of a safe stock was about 4,000 tons, about 75% of which was already on hand, the buyers here refused to become excited, and toward the end of the week the price declined a little.

Lead—Business in this metal was very active and about Dec. 20 independent producers began to be able to realize premiums over the price of the A. S. & R. Co. on good round lots. Inquiries became brisk with indications that further large business will be consummated. There was some gossip as to whether ammunition manufacturers might not be short of lead, as they were of copper. If that were the case, a sharp advance in price for lead might be looked for, the unsold stocks in the hands of producers being very small.

Spelter—This market was extraordinarily confused. Several producers reported an entire absence of demand and no business done. Others reported a considerable aggregate of transactions, representing a fair demand from galvanizers, and a larger demand from brass makers. The supply of metal available for prompt delivery is very small, although a moderate tonnage is to be had, of course at substantial premiums. In this position brokers and dealers are playing a considerable part, and producing much confusion. Sales of prompt spelter by producers were reported at 17@17¼c. The aggregate of these sales was, however, relatively insignificant. The bulk of the business done by producers last week was for first-quarter delivery, for which the average appeared to be about 15½c. in the early part of the week, and 15¾c. in the latter part. At the close first-quarter spelter was offered at 16c., while 15½c. was bid for it. On the other hand, smelters are free sellers of second-quarter spelter at 13@14c., without finding much interest in that delivery on the part of buyers. The situation may be summarized as follows: Prompt spelter is very scarce. Producers are pretty well sold for the first quarter of 1916, but still have liberal quantities to offer for that delivery, sales of which at present represent the bulk of the business. Most producers are eager sellers for the second quarter.

Arrivals at Baltimore for the week included 6,527 tons zinc concentrates from Port Pirie, Australia.

Zinc Sheets, base price remains at $22 per 100 lb. f.o.b. Peru, Ill., less 8% discount. Business has been steady, with good sales forward.

DAILY PRICES OF METALS IN NEW YORK

The quotations herein are our appraisal of the average markets for copper, lead, spelter and tin based on wholesale contracts for the ordinary deliveries of the trade as made by producers and agencies; and represent, to the best of our judgment, the prevailing values of the metals, reduced to basis of New York, cash, except where St. Louis is given as the basing point. St. Louis and New York are normally quoted 0.17c. apart.

The quotations for electrolytic copper are for cakes, ingots and wirebars. Electrolytic copper is commonly sold at prices including delivery to the consumers and is subject to discounts, etc. The price quoted for copper on "regular terms" is the gross price including freight to the buyer's works and is subject to a discount for cash. The difference between the price delivered and the New York cash equivalent is at present about 0.20c. on domestic business. The price of electrolytic cathodes is 0.05 to 0.10c. below that of electrolytic. Quotations for lead represent wholesale transactions in the open market for good ordinary brands. Quotations for spelter are for ordinary Prime Western brands. Only the St. Louis price is herein quoted, St. Louis being the basing market. We quote the New York price at 17c. per 100 lb. above the St. Louis price.

Silver quotations are in cents per troy ounce of fine silver.

Some current freight rates on metals per 100 lb. are: St. Louis-New York 17c.; St. Louis-Chicago, 6.3c.; St. Louis-Pittsburgh, 13.1c.

LONDON

Dec.	Silver	Copper Standard Spot	Copper Standard 3 Mos.	Copper Electrolytic £ per Ton	Copper Electrolytic Cts. per Lb.	Tin Spot	Tin 3 Mos.	Lead £ per Ton	Lead Cts. per Lb.	Zinc £ per Ton	Zinc Cts. per Lb.
16	25⅛	79½	79¼	97½	20.53	165	165½	28¼	6.06	90	18.96
17	25⅛	80½	81¼	98	20.65	167⅜	168½	28¼	6 05	90	18.95
18	26	..	.....	..	..	..	..	..	..	..	..
20	26 1/16	82⅜	83¼	99½	21.07	168½	169	28⅝	6 08	90	18 96
21	26 1/16	84¼	84¼	100½	21 18	167¼	168½	29	6 11	90	18 97
22	25⅛	82½	82½	100½	21 19	166	167	29	6 12	90	18 98

The above table gives the closing quotations on London Metal Exchange. All prices are in pounds sterling per ton of 2240 lb., except silver which is in pence per troy ounce of sterling silver, 0.925 fine. Copper quotations are for standard copper, spot and three months, and for electrolytic, price for the latter being subject to 3 per cent. discount. For convenience in comparison of London prices, in pounds sterling per 2240 lb., with American prices in cents per pound the following approximate ratios are given, reckoning exchange at 4.80. £15 = 3.21c.; £20 = 4.29c.; £30 = 6.43c.; £40 = 8.57c.; £60 = 12.85c. Variations, £1 = 0.21c.

Other Metals

NEW YORK—Dec. 22

Aluminum—The market is not so stiff, there being less pressure to buy, while supplies are a little better now, with a prospect of more to be had before long. Prices are a little easier, current quotations being 57@58c. for No 1 ingots, New York.

Antimony—The market shows little change from last week, but is not specially active. Quotations are a shade easier. Chinese and other ordinary brands are held at 38@39½c. per lb., according to size of order. Cookson's is scarce and such as is available is held at 55c per lb., New York.

In the "Journal" of Dec. 4 ordinary brands of antimony were quoted at 40c. per lb. for large lots, but it was mentioned that 42½c. had been named on some small business. Replying to an inquiry, we consider that the average price for antimony, ordinary brands, at that time was 40c., and so quote.

Quicksilver—The market is strong and active, sales being limited by supplies, which are still restricted. New York price is $130 per flask of 75 lb. for large orders, $135 per flask for smaller lots. San Francisco reports by telegraph an active market; sales earlier in the week at $115@120 per flask, with some dealers holding today at $130 per flask. London price is unchanged at £16 12s. 6d. per flask, with no discount from second hands.

Nickel—Business is good, with about the usual demand. Quotations for ordinary forms are 45@50c. per lb., according to size and terms of order. A premium of 5c. per lb. is charged for electrolytic nickel.

Gold, Silver and Platinum

NEW YORK—Dec. 23

Platinum—The market is excited and uncertain, supplies being still very limited and the future not all clear. It is difficult to fix prices, and dealers decline to make quotations except to regular customers. Sales are reported all the way from $90 up to $100 per oz. for refined platinum.

Our Russian correspondent writes that the market is very firm. A further increase of prices for the last fortnight is to be noted, partly owing to the rise in foreign exchange, partly in connection with the persistent demand both for internal markets and for abroad. Dealers abstain from sales, expecting yet higher prices. The quotations are: In Petrograd, 57,000@58,000 rubles per pood; at Ekaterinburg, 15 rubles per zolatnik, for crude metal, 83% platinum. These are equivalent to $56.40 and $56.35 per oz., respectively.

Silver has been fairly steady the past week. The approach of the holidays has brought on dullness in the general trading. Continental coinage demand may revive at any moment, and then there should be some improvement in price.

Zinc and Lead Ore Markets

PLATTEVILLE, WIS.—Dec. 18

The best price paid this week for 60% zinc ore was $88@100 per ton. The base price paid for 80% lead ore was $70 per ton. Shipments were curtailed by shortage of electric-drive power, occasioned by improvements being made at the central power plant of the Interstate Light and Power Co.

SHIPMENTS WEEK ENDED DEC. 18

	Zinc Ore, Lb.	Lead Ore, Lb.	Sulphur Ore, Lb.
Week	3,999,000	566,400	463,300
Year	202,210,750	7,195,540	29,088,510

Shipped during week to separating plants, 3,604,000 lb. zinc ore.

JOPLIN, MO.—Dec. 18

Blende, high price, $106.60; base per ton, 60% zinc, premium ore, $105; medium, $104@95; lower grades down to $85; calamine, base 40% zinc, $70@65; average selling price, all grades of zinc, $90.30 per ton. Lead ore, high price, $74.40; base per ton 80% metal content, $70@73; average selling price, all grades of lead, $71.66 per ton.

SHIPMENTS WEEK ENDED DEC. 18

	Blende	Calamine	Lead	Values
Totals this week...	9,819,400	919,220	2,162,970	$562,300
Totals this year...	567,310,780	44,629,950	$9,263,810	$26,320,850

Blende value, the week, $455,420; 51 weeks, $22,737,530.

Calamine value, the week, $29,370; 51 weeks, $1,156,290.

Lead value, the week, $77,510; 51 weeks, $2,427,030.

Last week's week-end buying, with some early buying this week, on a little higher price level than the general price of last week, was sufficient to create an excitement that advanced premium ores this week $15 per ton. The purchasers of premium ore are looking ahead a little, too, as a vacation of two weeks during the holidays will be observed by producers of high-grade ores more certainly than by producers of medium- or lower-grade ores. A light tonnage is reported, mainly because general buying was so late.

Iron Trade Review

NEW YORK—Dec. 22

The iron and steel markets continue to show unprecedented activity for this season of the year. The mills are being pressed with orders which they will have much difficulty in filling in anything like the time wanted. Domestic business is increasing, while export orders, after hesitating for a time, are coming in again rapidly.

The pressure for materials for car building, ship building and structural work is becoming strong. Structural business, which was rather slow for a time, is increasing rapidly. Fabricators in the East have taken large contracts and are urging deliveries of steel to prevent delays.

The pig-iron market is strong and active. Foundries, which have not contracted far ahead are finding difficulty in getting iron except at an advanced price.

Freight congestion has been increased by bad weather and is presenting serious difficulties. Some furnaces have been hampered by trouble in getting coke as they need it.

Some progress has apparently been made with the organization of the new combination which is to include the Cambria Steel, the Lackawanna Steel and the Youngstown Sheet and Tube companies. Options have been taken on the stock, but no definite details has been given out. The Republic Iron and Steel Co. is not concerned in the merger.

Pig-iron production in Alabama in November is reported at 212,000 tons.

Iron and steel exports for which quantities are reported are given by the Bureau of Commerce in October at 351,251 long tons, against 147,293 tons in October, 1914. For the 10 months ended Oct. 31 the total so reported was 1,291,018 tons in 1914, and 2,818,679 tons in 1915; an increase of 1,527,661 tons.

PITTSBURGH—Dec. 21

In point of new buying finished steel products are much less active this week. While with such a rush to buy in the past few weeks, and mills now so thoroughly sold up, a decrease in activity was unavoidable, the sharpness of the decrease is attributed to the arrival of the holiday season. There is as great a disposition as ever to specify on current contracts, but the volume of this business is somewhat reduced, as many buyers had already specified their full quotas to Dec. 31.

Steel prices show as sharp an advancing tendency as ever. Wire products are up today $2 a ton, making nails $2.10. Bars, plates and shapes advanced last week from 1.70c., a price quoted by a few sellers on certain business, to a general minimum of 1.80c., and a further advance is predicted for early next month. Hoops are up $2 a ton to 2c., and black sheets a like amount, to 2.60c. for 28 gage.

The Pennsylvania R.R. has placed an embargo on all iron and steel destined east for lighterage at Jersey City or Waverly, while the movement to line consumers is greatly congested. The coal and coke movement east is largely embargoed. The Baltimore & Ohio restrictions are almost equally severe. Railroad officials who a few weeks ago expressed confidence that the situation would soon improve now admit that it is not only worse, but may grow still worse in the next two or three weeks, particularly if bad weather intervenes.

In the circumstances iron and steel shipments for export are practically cut off. The mills are shipping correspondingly more material to the domestic trade, which is very glad to have the additional material. Total shipments of steel for export, direct and indirect, probably represent no more than about 20% of the total shipments at the present time.

Pig Iron—Inquiry for pig iron is by no means heavy, but small buying sends prices upward. There have been small sales of bessemer at $19.50, with no $19 iron in sight, and most sellers holding for $20. In foundry iron $18 is no longer heard, and $18.50, which was done a fortnight ago in the case of some deliveries, is now the minimum. Several small sales of basic iron are reported at $18, the quotation named in last week's report. Producers evidently expect a shortage of pig iron, and are predicting much higher prices. Consumers have all covered to an extent, but some are expected to require additional tonnages through their consumptive requirements having increased. There is some inquiry for foundry iron for third quarter, for which delivery furnaces quote 50c. higher than for early delivery. We quote: Bessemer, $19.50@20; foundry, $18.50@19; gray forge, $18@18.50; malleable, $18

@18.50; basic, $18, f.o.b. Valley furnaces, 95c. higher delivered Pittsburgh.

Ferromanganese—The market is much stronger. At least one English producer is quoting $110 on contract, Baltimore, instead of $100, while some domestic producers quote as high as $125 on contract. Prompt lots generally bring $100@105. Consumers have been buying steadily in the past few weeks and are probably fairly well covered for the next six to nine months.

Steel—After several weeks of a practically nominal market in billets there have been open-market sales of ordinary soft openhearth billets to the extent of several thousand tons at $35, maker's mill, Pittsburgh district, $4 a ton above the nominal quotation which some mills have lately mentioned as probably representing the market. It would appear that more openhearth steel could be sold at $35. Bessemer billets are quotable at about $32. Sheet bars would not be offered at lower prices than billets, but sheet mills could not afford to pay such prices, and must be content with their contract tonnages, which cover them fairly well. Forging billets are $52@55 and rods nominally $40 at mill.

FERROALLOYS

Ferrosilicon is in demand and firm. For high-grade, 50% up, the quotation is $83@85 per ton at furnace in the Pittsburgh District. Bessemer ferrosilicon is also firm, prices varying from $28 at furnace for 10% up to $38 for 16% alloy.—**Ferrotungsten** remains high with some variations in price.—**Tungsten** metal is a little easier; a sale is reputed this week at $6.50 per lb. for a lot of 1,000 lb., 98% pure.—**Molybdenum** metal is reported sold at $1.50 per lb. Most of the metal now offered is high in sulphur, and good metal is scarce.

FOREIGN IRON TRADE

British Foreign Trade in Iron and Steel and in manufactures thereof 10 months ended Oct. 31, as valued by the Board of Trade returns:

	Exports	Imports	Excess
Iron and steel	£32,736,119	£8,853,825 Exp.	£23,882,294
Hardware, etc.	24,254,232	12,350 392 Exp.	11,903,840
Totals	£56,990,351	£21,204,217 Exp.	£35,786,134
Totals, 1914	79,449,681	21,524,575 Exp.	57,925,106

The total tonnage of iron and steel exported, 3,441,157 tons in 1914, and 2,640,569 tons in 1915; imported, 1,502,648 tons in 1914, and 995,297 tons this year.

Pig-Iron Production in Germany in October is reported by the German Iron and Steel Union at 1,076,343 metric tons; which is 40,265 tons more than in September and about two-thirds of the normal output. For the 10 months ended Oct. 30 the total make was 12,746,729 tons in 1914, and 9,741,871 tons in 1915; a decrease of 3,004,858 tons this year.

Steel Production of Germany nine months ended Sept. 30, as reported by the German Iron and Steel Union, in metric tons:

	Basic	Acid	Total
Converter	4,829,819	118,003	4,947,822
Open hearth	3,883,319	177,922	4,061,241
Direct castings	321,553	124,931	446,484
Crucible	.....	75,441	75,441
Electric	.....	87,262	87,262
Total	9,034,691	583,559	9,618,250
Total, 1914	11,716,855	508,022	12,224,877

The total number of works in operation on Sept. 30, or at any time during the nine months, was 231, against 242 last year.

Swedish Iron Production for the seven months ended July 31 is reported as follows:

	1914	1915	Changes
Pig iron	432,000	426,500	D. 5,500
Wrought iron blooms	78,300	65,200	D. 13,100
Converter steel	63,000	52,200	D. 10,800
Openhearth steel	254,800	282,400	I. 27,600

The production of finished iron and steel in all forms for the first half of 1915 was 218,300 tons.

IRON ORE

Some large sales of Eastern iron ore have been made, doubtless stimulated by the Lake activity. Among these are heavy sales of Port Henry ore at 8¼@9c. per unit, delivered, which is about 75c. per ton over last year. Some lump ore is reported sold at $4 per ton at mine. A good tonnage of other New York and New Jersey ores has been sold at 8¼@8¾c. per unit, delivered.

Of the total shipments of Lake iron ore in November, 4,308,295 tons, or 97%, went to Lake Erie ports.

Imports at Baltimore for the week were 8,650 tons manganese ore from India and 5,600 tons from Brazil.

Imports of manganese ore in the United States in September were 29,959 tons. For the nine months ended Sept. 30, the imports were 215,271 tons in 1914 and 173,992 tons in 1915; a decrease of 41,282 tons, or 19.2%, this year.

An interesting table, published by the "Iron Trade Review," gives the season prices of Lake Superior iron ore for 27 years. The highest quotations were in 1890, when Old Range ore brought $5.50 for bessemer and $5.25 for non-bessemer; no Mesabi ore was then being shipped. Since that year the highest prices were in 1899, when $5.50 was paid for Old Range and $4.50 for Mesabi bessemer; $4.20 for Old Range and $4 for Mesabi nonbessemers. Other high years were 1906 and 1909, when the rates were $5 for Old Range and $4.75 for Mesabi bessemers; $4.20 and $4 for nonbessemers. The rates for 1916 are higher than in 16 out of 27 years.

to foreigners as well as to Spanish subjects.

OTHER ORES

Some trial shipments of antimony ore have been made from Honduras to New York. The mine has been known for some time, but has been little worked on account of transportation difficulties. The ore shipped is mined in the vicinity of the interior village of Yoro and has to be transported six days by pack mule to the Sulaco River, thence two days by canoe down the river to Pimienta, where rail connection is made for Puerto Cortes.

Señor D. Domingo Orueta, who recently discovered in Spain deposits of platinum, chromium and nickel, has relinquished his claims to the Spanish Government. By royal decree, published Nov. 17 in the "Gaceta de Madrid," official organ of the Spanish Government, the territorial limits of the mines are defined. Concessions to exploit the mines are obtainable from the Spanish Government by foreigners as well as natives.

COKE

Coke production for the week in the Connellsville region is reported by the "Courier at 451,896 short tons; shipments, 451,175 tons. Shipments of Greensburg and Upper Connellsville districts, 40,967 tons. No material increase is probable until labor conditions improve.

Coal Production of Austria nine months ended Sept. 30, in metric tons:

	1914	1915	Changes
Coal mined	11,700,541	12,088,961	I. 388,420
Brown coal	18,337,727	16,367,481	D. 970,246
Coke made	1,771,938	1,374,770	D. 397,168
Briquettes made	301,763	345,797	I. 44,034

Of the briquettes reported this year 190,047 tons were made from brown coal, or lignite.

Chemicals

NEW YORK—Dec. 29

The general market is fairly active with rather a strong tone. Business is for the most part good for this season of the year.

Arsenic—Business is quiet, but very steady and there is no change. Prices are $3.75@4 per 100 lb. for both spot and futures.

Copper Sulphate—Stocks are low and some large producers are out of the market for the time being. The quotations are unchanged at $10 per 100 lb. for carload lots and $10.25 per 100 lb. for smaller parcels.

Nitrate of Soda—Imports have been smaller recently and stocks not at all excessive. Prices continue firm at $3.20 per 100 lb. for spot and January; $3.15@$3.20 for futures.

Sulphuric Acid—The spot market is nominal with dealers' stocks very small. Large makers are in a position to name shipment figures and business is being booked for 1916, according to the "Oil, Paint and Drug Reporter." Contract shipments are quoted at $27@35 per ton in tanks for 60 deg., according to quantity and time of delivery. Contracts for 66 deg. $45@50 per ton for prompt, $37 per ton for first half of next year and $40 per ton over the year in tank cars. Smaller quantities in carboys command premiums according to size.

Imports and Exports of Fertilizing Chemicals in the United States nine months ended Sept. 30, in long tons:

	Imports		Exports	
	1914	1915	1914	1915
Kainit	229,041	6,646	...	...
Manure salts	157,710	13,647	...	...
Other potash salts	154,258	56,881	2,746	900
Nitrate of soda	430,136	669,383	7,384	16,846
Sulphate of ammonia	59,054	27,193	150	1,204
Phosphates	...	...	915,360	271,584

Exports include reëxports of foreign material. Some phosphates are imported, but are not given separately in the returns.
